Short-Circuit Current of Induction Motors and Generators

BY R. E. DOHERTY and E. T. WILLIAMSON
General Electric Company, Schenectady, N. Y.

There has been a rather prevailing opinion that a sudden short circuit of an induction generator would not cause a serious initial rise in current such as occurs in synchronous generators. This has led to the proposal of the use of such machines as a partial solution of the short-circuit problem on a-c. systems. Theoretical considerations and experimental data given in the paper show that, on the contrary, there is in the induction generator, just as in the synchronous machine, a serious initial rush of current which is limited only by the leakage reactance of the machine. The only difference is that the transient is shorter in the induction machine, and the current dies down, of course, to zero instead of to the sustained value which occurs in an excited synchronous generator.

THE problem of short circuits on alternating-current systems is ever becoming more pressing. The calculation of the short-circuit current of the generating apparatus is therefore of utmost importance. This calculation for synchronous machines has been covered in an Institute paper[1] presented in 1918. The present paper deals with the induction machine. This study was prompted by the suggestion, which has now and then been proposed, that the installation of induction generators might possibly be a partial solution of the short-circuit problem. The basis for the suggestion was, of course, the supposition that the initial short-circuit current of this type of machine was negligible. This supposition rested on the idea that, unlike the synchronous machine, the induction generator has no permanent excitation, and therefore when the terminals are short-circuited and all electrical connection thus removed, the existing small current will die out exponentially. A study of the problem however, indicated that this was not the case. Subsequent tests given herewith confirm that view and show that on large induction generators serious initial short-circuit currents may be expected, just as on synchronous machines.

From a search of the literature it appears that very little has been published on this subject. In 1910 Messrs. Spooner and Barnes[2] published an article on "The Induction Generator," giving the results of comparative short-circuit tests on synchronous and induction generators. Quoting from the article, "Theory would indicate that a short circuit would be equivalent to a withdrawal of the exciting current from the induction generator and hence it would cease to deliver energy. The accompanying oscillogram, which is a typical current record, shows this to be the case." These tests, however, were made on a small machine (10 h. p.) of relatively high resistance and therefore are not, as will be pointed out later, representive of conditions that would exist in large induction generators. In the same year a paper[3] by G. W. Meyer stated that, "If induction generators are used, a short circuit in the line does not cause an abnormal rise of current in these machines. They simply cease to generate."

The present investigation, however, shows that the sudden short circuit of an induction generator or motor, like that of a synchronous machine, is initially

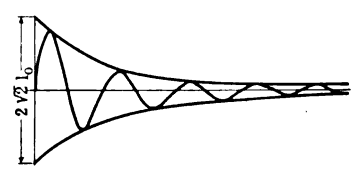

Fig. 1—Diagram Showing Method of Determining the Short-Circuit Current

many times normal, and depends in value upon the total leakage reactance. Unlike the synchronous machine, there is no "sustained" current. Instead the current decreases in a few cycles, from the high value existing in the moment of short circuit to zero. This is shown in Fig. 1.

The comparison of the *initial* short-circuit currents of induction and synchronous machines is really a comparison of practically identical phenomena. In either case, the relation of the flux in the machines to the stator and rotor windings is in fundamental respects the same. In either, the poles of the magnetic flux rotate at synchronous speed with respect to the stator windings, and at the same time the flux is linked

To be presented at the Midwinter Convention of the A. I. E. E., New York, February 16-18, 1921.

with the closed rotor winding. The fact that in normal operation the flux of the induction machine "slips" with respect to the rotor winding, does not change the circumstance that it is nevertheless at all instants linked with the closed winding. Neither does the fact that the rotor winding of the synchronous machine has direct-current excitation whereas that of the induction machine has not, alter in a fundamental way the conditions which determine the initial current; although it does, of course, determine altogether the difference between the final values.

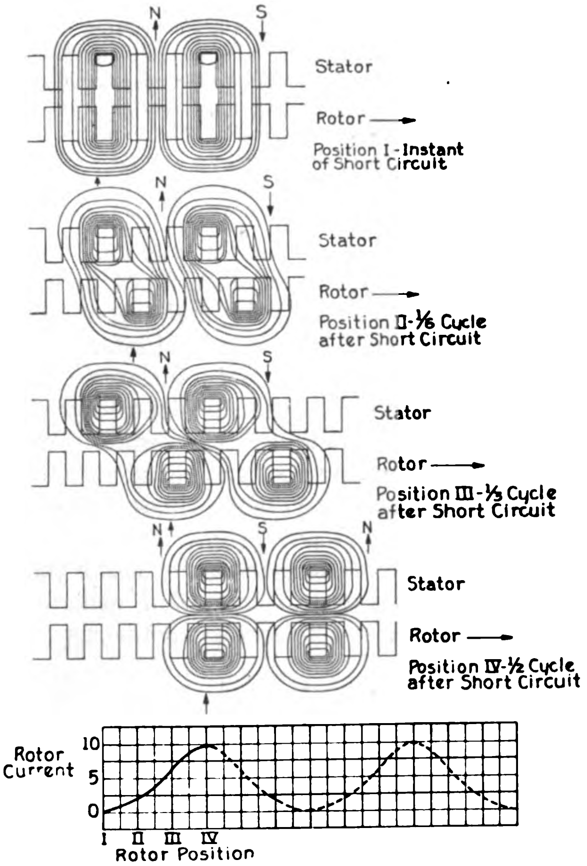

FIG. 2—DISTRIBUTION OF PRIMARY AND SECONDARY FLUX FOR DIFFERENT POLE POSITIONS AFTER SHORT CIRCUIT

It follows from Lentz's Law that *a closed electric circuit, without resistance, must persist magnetically in the same condition as at the instant of closing; that is, must contain as long as it is closed, the same number of magnetic interlinkages.* While both stator and rotor windings of course do contain some resistance, it is yet small enough to make possible at least a qualitative study of initial conditions on the assumption that the resistance is zero; and from that, one may form an idea of the modification which a small value or resistance would involve.

Suppose an induction motor is running at full voltage no load, and that the terminals of the stator winding are suddenly short-circuited. For convenience assume that when this happens, no flux is linked with the stator coils. Then, by Lentz's Law and the assumption of zero resistance, no flux can enter those coils. The rotating flux attempting to enter the winding causes sufficient current to flow in the winding, *i. e.* sufficient m. m. f., to force the flux out, *i. e.*, tends to "kill" the magnetic field. But this field, being linked with the closed rotor circuit, can not die out. It can not decrease at all, since doing so would involve a change of interlinkages. Neither could the flux cease rotation for the same reason. Therefore, since the flux can not enter the stator and yet must emanate from the rotor surface and remain linked with the rotor coils, it follows that it must pass through the leakage paths, largely along the air gap and tooth tips between the stator and rotor winding and return to the rotor. Now the m. m. f. required to maintain normal flux in the leakage paths is greater than the m. m. f. of normal current in the ratio of normal flux to the leakage flux produced by normal current. Hence the m. m. f. at short circuit depends directly upon the leakage reactance of the machine.

It is clear that the stator current, generated by the rotating flux, is alternating, whereas the rotor current, being that required to maintain a direct flux, is itself direct.

The foregoing assumed that the stator interlinkages were zero when the short circuit occurred. Actually, in a polyphase machine, the entire flux is linked at all instants with some phase or phases. Hence the stator interlinkages must always be the same, *i. e.*, those due to normal flux regardless of the instant of short circuit. This means that there must always be two sets of magnetic poles of practically equal intensity. See Fig. 2. One, just mentioned, linked with the closed stator winding and therefore stationary in space; the other, described in the foregoing, linked with the rotor winding and therefore rotating in space. And just as the latter causes direct current in the rotor and alternating current in the stator, so does the former cause direct current in the stator and alternating current in the rotor. Thus the total current in either the stator or the rotor is the resultant of an alternating and a direct component.

Obviously these components must be roughly of the same magnitude, since the m. m. f. in either case is that required to maintain normal flux in the leakage paths. Actually the a-c. component of the stator is less than the d-c. component because the flux linked with the rotor (which causes the a-c. component in the stator) is slightly less than the flux linked with the stator (which causes the d-c. component in the stator).

It is clear from the above considerations, that, assuming the same leakage inductance, the initial value of short-circuit current will be the same in a given machine whether it is operating as induction motor, or as a synchronous motor with direct-current excitation in the secondary winding. There would, of course, be some difference in the leakage inductance when operated as an induction machine and when operated as a synchronous machine.

The effect of shaft load upon the value of the short-circuit current is small. The primary flux per pole is a fixed value for a given voltage. At no load all of this flux, except 5 per cent or so, is linked also with the secondary pole, the 5 per cent being the leakage due to the exciting current. Under load, the per cent by which the remaining 95 per cent linked with the rotor, is reduced is not in direct proportion to the increase in the stator current on account of the phase difference between the

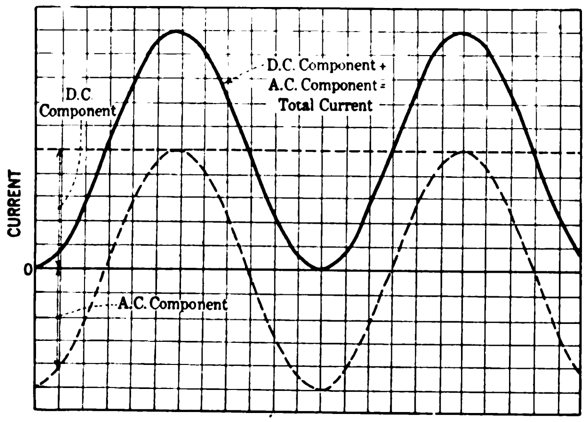

FIG. 3—CURVE SHOWING THE SUDDEN SHORT-CIRCUIT CURRENT OF INDUCTION MOTOR IF IT IS ASSUMED THAT THE RESISTANCE IS ZERO

exciting current and the load current, and therefore between leakage fluxes produced by those currents. In other words, the primary flux per pole is unchanged, the rotor flux is further reduced by 5 per cent, leaving, say, 90 per cent. Thus the primary d-c. component will be the same, the primary a-c. component and both components of the secondary current will be less by about 5 per cent. Hence the difference in the total current is small.

Assuming no resistance, the general shape of the short-circuit current wave would be as shown in Fig. 3.

With resistance, which is present in every case, the flux linked with the two members will die out as an exponential function of time. Such a short-circuit current wave is plotted in Fig. 4. In this case the d-c. component of the primary is:

$$i_1 \text{ d-c.} = \sqrt{2}\, I_{01}\, \epsilon^{-\frac{r_1}{L_0} t}$$

and the a-c. component is

$$i_1 \text{ a-c.} = -\sqrt{2}\, I_{01}\, \epsilon^{-\frac{r_1}{L_0} t} \cos \omega t$$

Then the total primary current is

$$i_1 = i_1 \text{ d-c.} + i_1 \text{ a-c.} = \sqrt{2}\, I_{01}\, \epsilon^{-\frac{r_1}{L_0} t} (1 - \cos \omega t)$$

Where,

i_1 = instantaneous primary current

I_{01} = r. m. s. of the initial value of a-c. component

$$\text{in primary} = \frac{\text{(normal voltage per phase)}}{\text{(impedance per phase)}}$$

$$= \frac{E}{\sqrt{r^2 + X^2}}$$

r = total resistance per phase = $r_1 + r_2$

r_1 = resistance per phase of primary

r_2 = resistance per phase of secondary reduced to primary terms

X = total leakage reactance per phase (primary terms)

$L_0 = X \div 2 \pi f$

The above equations apply when the ratio $r_1/L_0 = r_2/L_0$, that is, when $r_1 = r_2$.

Resistance does not appreciably affect the initial value of short-circuit current since the resistance is usually small compared with the reactance. For example in a case where $r = 5$ per cent and $X = 20$ per cent the error due to neglecting r in the impedance would be only 3 per cent, which is negligible. Resistance does, however, affect the duration of the short-circuit current, since, in this case, r appears as a factor of direct proportionality in the attenuation factor r/L.

In general, the primary and secondary members are magnetically very similar. That is, the ratio L/r is very nearly the same for either member. Hence the two fluxes die out at about the same rate. A conception of this rate can be had from the following illustration. Take, for example, a 60-cycle machine with 2.5 per cent resistance loss in each member, (*i. e.* 2.5 per cent resistance drop in each member at

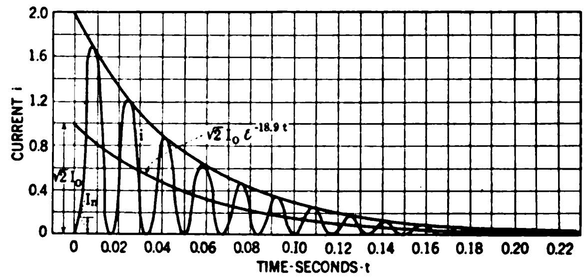

FIG. 4—CALCULATED CURVE OF THE SUDDEN SHORT-CIRCUIT CURRENT OF AN INDUCTION MOTOR

Equation of short-circuit current

$$i = \sqrt{2}\, I_0 \,(E^{-18.9t} - E^{-18.9t} \cos \omega t) = \sqrt{2}\, I_0\, E^{-18.9t} (1 - \cos \omega t)$$

Assumed Constants

	Stator	Rotor
	r = 1 per cent	r = 1 per cent
Total	x = 20 per cent	
	$\frac{r}{L_0} = 18.9$	$\frac{r}{L_0} = 18.9$

I_N = normal rated current

$$I_0 = \frac{100}{x} I_N = 5\, I_N$$

normal current) and a leakage reactance of 20 per cent. Then the time constant is,

$$\frac{L_0}{r} = \frac{\frac{20}{2 \pi f}}{2.5} = \frac{20}{2 \pi \times 60 \times 2.5}$$

$$= 0.021 \text{ second}$$

which means that in four times 0.021 second, or 0.084 second, that is five cycles, the flux, and therefore the current, will have practically died out. It is

very important to note that at one-half cycle (0.0083 sec.) when the current reaches the maximum peak (that is, when assuming no transient, sufficient m. m. f. would necessarily exist to support twice

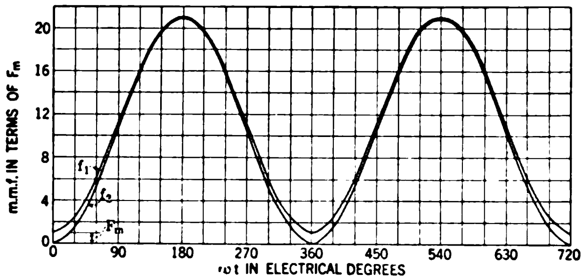

FIG. 5—CALCULATED CURVE OF M. M. F. AT SHORT CIRCUIT OF A POLYPHASE INDUCTION MOTOR

Primary m. m. f. $= f_1 = \dfrac{F_m}{\dfrac{P_1 P_2}{P_m^2} - 1} \left[\dfrac{P_1 P_2}{P_m^2} - \cos \omega t \right]$

Assumed Constants

$$\frac{P_m}{P_1} = \frac{P_m}{P_2} = 0.95$$

Secondary m. m. f. $= f_2 = F_m \dfrac{P_1}{P_m} \left[\dfrac{1 - \cos \omega t}{\dfrac{P_1 P_2}{P_m^2} - 1} \right]$

normal flux in the leakage paths) the flux has already decreased to 70 per cent of its initial value. This is important because if the resistance is less, say 1 per cent, as in the case of large induction generators, the

	r = 2.1 per cent		r = 2.1 per cent
Total	x = 16.5 per cent		
	$\dfrac{r}{L} = 48.3$		$\dfrac{r}{L} = 48.3$

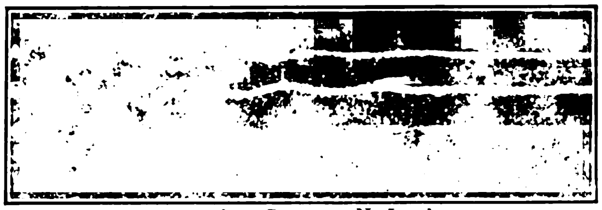
I_n = normal rated current

$$I_0 = \frac{100}{x} I_n = 6.06\, I_n$$

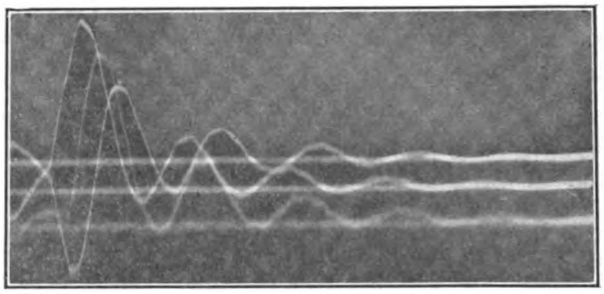
flux, and therefore the current at this critical instant, would be higher. Moreover, the leakage paths would be more nearly saturated, thus causing an additional increase in current. Using 1 per cent resistance in the above illustration, the flux at the end of one-half cycle would be only 85 per cent instead of 70 per cent initial value. Such a case is plotted in Fig. 4.

In connection with this investigation four conditions of short circuit have been considered. The calculated curves of m. m. f. are plotted for each case and accompanying oscillograms show the actual current curves for two cases. Equations are developed

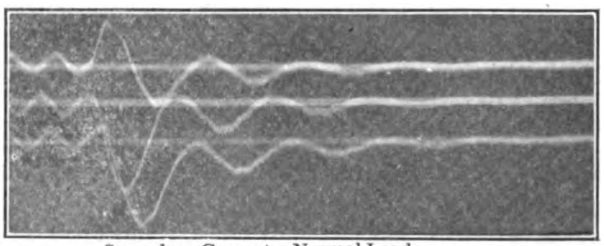
Primary Current—No Load.



Secondary Current—No Load.



Primary Current—Normal Load.



Secondary Current—Normal Load.

FIG. 7—OSCILLOGRAMS OF THE SHORT-CIRCUIT CURRENT OF AN INDUCTION MOTOR

150-h. p., three-phase, 60-cycle, 720-rev. per min., 440-volt three-phase short circuit at 440 volts.

in the Appendix for each of the cases and are as follows:

Case I. Polyphase short circuit on a polyphase induction motor or generator. The equation for the primary m. m. f. is,

$$f_1 = \frac{F_m}{\dfrac{P_1 P_2}{P_m^2} - 1} \left[\frac{P_1 P_2}{P_m^2} - \cos \omega t \right] \quad (9)$$

and for the secondary m. m. f. is,

$$f_2 = F_m \frac{P_1}{P_m} \left[\frac{1 - \cos \omega t}{\dfrac{P_1 P_2}{P_m^2} - 1} \right] \quad (10)$$

Fig. 5 shows the calculated curves plotted from these equations.

This case of a polyphase short circuit is the most important and the equations have, therefore, been reduced to terms of current instead of m. m. f., and the effect of resistance is taken into account by introducing the transient factor. The equation for the primary current is,

$$i_1 = \sqrt{2}\, I_{01}\, \epsilon^{\frac{r_1}{L_0}t}\ (1 - \cos\omega t) \qquad (26)$$

and for the secondary current is,

$$i_2 = \sqrt{2}\, I_{02}\, \epsilon^{-\frac{r_2}{L_0}t}\ (1 - \cos\omega t) \qquad (27)$$

The curve in Fig. 6 is plotted from equation (26) and Fig. 7 shows the oscillogram of the current from test.

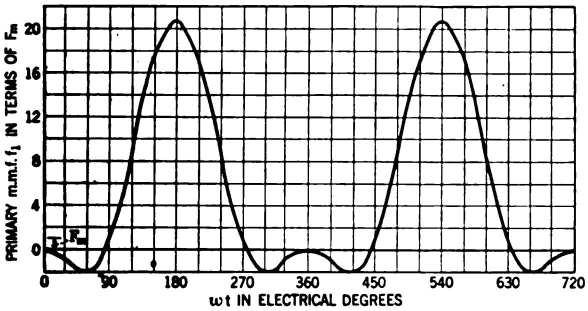


FIG. 8—CALCULATED CURVE OF PRIMARY M. M. F. AT SUDDEN SHORT CIRCUIT OF A POLYPHASE INDUCTION MOTOR HAVING THE SECONDARY EXCITED WITH THE DIRECT CURRENT.

$$f_1 = F_m \frac{P_m}{P_1}\left[1 - \frac{1}{\frac{P_1 P_2}{P_m^2} - 1}\left\{\frac{P_1 P_2}{P_m^2}\cos\omega t - \frac{1}{2}(1 + \cos 2\,\omega t)\right\}\right]$$

Assumed Constants

$$\frac{P_m}{P_1} = \frac{P_m}{P_2} = 0.95$$

Case II. Polyphase short circuit on a polyphase induction machine having one phase of the rotor excited with direct current, that is, operating as a synchronous machine. The equation for the primary m. m. f. is,

$$f_1 = F_m \frac{P_m}{P_1}\left[1 - \frac{1}{\frac{P_1 P_2}{P_m^2} - 1}\left\{\frac{P_1 P_2}{P_m^2}\cos\omega t - 1/2\,(1 + \cos 2\,\omega t)\right\}\right] \qquad (32)$$

and for the secondary m. m. f. is,

$$f_2 = F_m \frac{\frac{P_1 P_2}{P_m^2} - \cos\omega t}{\frac{P_1 P_2}{P_m^2} - 1} \qquad (31)$$

These equations are plotted in Fig. 8 and Fig. 9. The test curve is shown in Fig. 10. The difference between the test curve for f_1 and the curve of stator current in Fig. 10 can probably be accounted for by the fact that the rotor resistance is increased by a rheostat and an exciter in the circuit. This causes the secondary flux to die down rapidly, thus causing the a-c. component of fundamental frequency in the

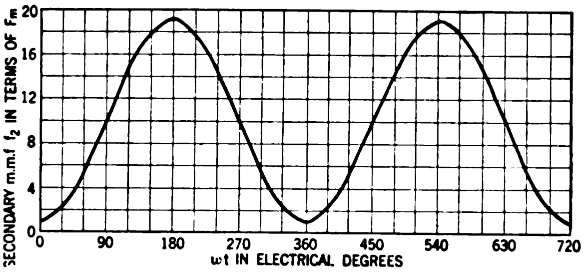

FIG. 9—CALCULATED CURVE OF SECONDARY M. M. F. AT SUDDEN SHORT CIRCUIT OF A POLYPHASE INDUCTION MOTOR HAVING THE SECONDARY EXCITED WITH DIRECT CURRENT

$$f_2 = F_m\left[\frac{\frac{P_1 P_2}{P_m^2} - \cos\omega t}{\frac{P_1 P_2}{P_m^2} - 1}\right]$$

Assumed Contents

$$\frac{P_m}{P_1} = \frac{P_m}{P_2} = 0.95$$

primary to die down faster than the second harmonic in the primary.

Case III. Single-phase short circuit on a polyphase induction machine under the assumption that the third line is opened at the instant the other two are

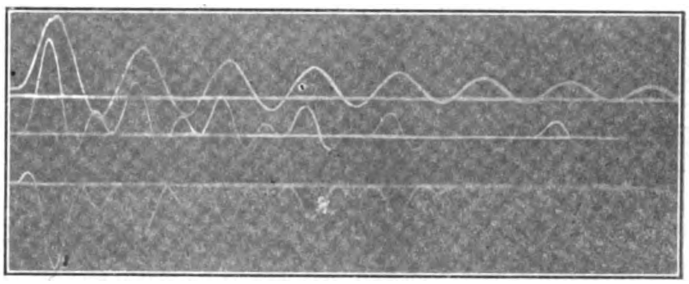

FIG. 10—OSCILLOGRAM OF THE SHORT-CIRCUIT CURRENT OF AN INDUCTION MOTOR WITH ONE PHASE OF ITS SECONDARY EXCITED WITH DIRECT CURRENT

Secondary excited with direct current.
Upper curve—d-c. current in rotor.
Middle curve—primary current.
Lower curve—primary current.

short-circuited. The equation for the primary m. m. f. is,

$$f_1 = F_m \frac{\frac{P_1 P_2}{P_m^2}\cos\delta - \cos\omega t}{\frac{P_1 P_2}{P_m^2} - 1} \qquad (36)$$

and for the secondary m. m. f. is,

$$f_2 = F_m \frac{P_m}{P_2} \left[1 - \frac{1}{\frac{P_1 P_2}{P_m^2} - 1} \left\{ \frac{P_1 P_2}{P_m^2} \cos\delta \cos\omega t - 1/2\,(1 + \cos 2\,\omega t) \right\} \right] \quad (39)$$

It will be noted that the curves from these equations with $\cos\delta = 1$, would be identical with those of Case II except that in this case f_1 corresponds to f_2 of the other, and *vice versa*. No test was made under these conditions.

Case IV. Single-phase short circuit on an induction machine with direct current in one phase of the secondary and the other phases open, that is,

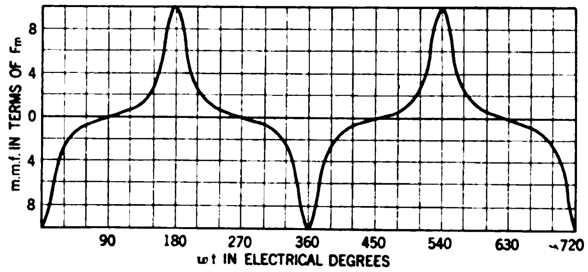

Fig. 11—Calculated Curve of Primary m. m. f. at Sudden Short Circuit of a Polyphase Induction Motor When Operating Single-Phase

$$\text{Primary m. m. f.} = f_1 = -F_m \frac{P_2}{P_m} \left[\frac{\cos\omega t}{\frac{P_1 P_2}{P_m^2} - \frac{1}{2}(1 + \cos 2\,\omega t)} \right]$$

Assumed Constants

$$\frac{P_m}{P_1} = \frac{P_m}{P_2} = 0.95$$

operating as a single-phase synchronous machine. The equation for the primary m. m. f. is,

$$f_1 = -F_m \frac{P_2}{P_m} \; \frac{\cos\omega t}{\frac{P_1 P_2}{P_m^2} - 1/2\,(1 + \cos 2\,\omega t)} \quad (44)$$

and for the secondary m. m. f. is,

$${}_2 = F_m \frac{P_1 P_2}{P_m^2} \; \frac{1}{\frac{P_1 P_2}{P_m^2} - 1/2\,(1 + \cos 2\,\omega t)} \quad (45)$$

Fig. 11 is the curve for f_1 plotted from equation (44). A test was not made under these conditions.

Tests

The tests in connection with this investigation were made on a 150-h. p., three-phase, induction motor. The short circuits were made with the machine operating at normal voltage, no load, and normal voltage, full load. Fig. 12 shows the diagram of connections indicating the position of the oscillograph shunts and the short-circuiting switch. About 50 oscillograms were taken. Typical results are given in Table I.

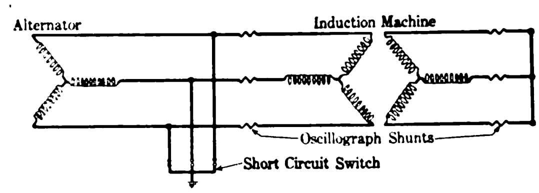

Fig. 12—Diagram of Connections for Short-Circuit Tests

It is important in appraising results of short-circuit tests to note the method by which the "short-circuit current" is determined from the oscillogram. The method used in these tests is illustrated by Fig. 1. The curves joining the crests (both positive and negative) of the wave are projected backward to the axis of zero time. The same exponential is used to extend the curve back from the first crest to the axis of zero time as was found to apply to the curve between the first two crests. The intercept at the axis of zero time is taken as twice the maximum value of the a-c. component.

†Per cent reactance $= 100 \times \dfrac{\text{normal current}}{\text{initial current (primary)}}$

‡Oscillogram shown in Fig. 7.

In the more general aspects these tests confirm the theory outlined in the foregoing. The particulars in which the tests do not agree, but which for the most part can be explained, are:

1. The attenuation factor r/L is higher than measured by the ohmic resistance and the inductance from the impedance test. That is, the current dies down in about 75 per cent of the calculated time. The calculated curve, Fig. 6, shows that six cycles are required for the current to die out, while the test curve, Fig. 7, shows that the current died out in four and one-half cycles.

This discrepancy can be explained by the facts that on account of eddy losses, etc., the effective resistance is greater than the measured ohmic resistance, and that on account of saturated leakage paths, the inductance is lower than that indicated by impedance test taken at near half voltage: both of these would shorten the transient.

2. The secondary m. m. f. at short circuit is apparently 60 to 75 per cent of the primary m. m. f. For this there seems to be no adequate explanation. This result, although roughly indicated by the tests, should, for reasons already given, be accepted with reserve.

3. The leakage reactance from results of these tests is about 25 per cent lower than that calculated from ordinary impedance tests (*i. e.* calculated reactance = 17 per cent, reactance from short-circuit tests = 13 per cent). This is explained by the fact that under short-circuit conditions the leakage paths are highly saturated, hence more current is required to maintain the flux. The amount by which the leakage reactance is reduced depends upon the extent to which the flux has died down at the end of the first half cycle after short circuit (at which time the greatest flux exists in the leakage paths). It therefore depends upon the time constant X/r.

In such a machine as the present 150-h. p. motor, in which X/r is about 6, the flux dies down to about 60 per cent of its initial value in the first half cycle, and completely disappears, as shown in Fig. 7, in four or five cycles. On the other hand, in a machine with $X/r = 20$, the flux would die down to only 85 per cent of its initial value in one-half cycle. This would mean not only more current on account of saturated leakage paths, but also an additional increase because it is now necessary to maintain 42 per cent more flux in those paths (*i. e.* $85/60 = 1.42$). Hence in large machines of relatively low resistance the total leakage reactance under conditions of short circuit would be less than the reactance from impedance test by a difference greater than the 25 per cent noted in this test. On the contrary the difference would be *less*, if X/r were smaller.

CONCLUSIONS

1. The sudden short-circuit current of a polyphase induction motor or generator, like that of a synchronous machine, is initially many times the normal rated current, and consists of an a-c. and a d-c. component, of approximately equal magnitudes in both primary and secondary.

2. The initial value of the r. m. s. of the a-c. component is equal to the impressed voltage divided by the total leakage reactance.

3. It follows that, assuming the same leakage inductance, the initial current will be the same whether the machine is short-circuited as an induction machine, or as a synchronous machine with the secondary excited with direct current.

4. The leakage reactance under short-circuit conditions is lower than indicated by ordinary impedance tests. As pointed out in paragraph (3) under TESTS, this is an important point to be considered in the design of certain large induction generators in which relatively low values of resistance may exist.

5. The actual duration of the transient is less than that indicated by the ohmic resistance and the reactance from impedance test, both because eddy currents increase the effective resistance, and saturation of leakage paths decrease L. Hence, r/L is increased.

6. Adding resistance to the primary winding will cause the d-c. component of that winding, and therefore the a-c. component of the secondary, to die out rapidly, and it will prolong the transient of the primary a-c. component and secondary d-c. component.

7. The effect of load upon the value of the short-circuit current is practically negligible.

The authors wish to acknowledge the assistance of Messrs. H. Maxwell, A. E. Averett, C. M. Davis and E. J. Burnham in making this investigation.

APPENDIX

ASSUMED CONDITIONS

The following assumptions are made in the development of the equations of short-circuit current: (1) Sine wave, m. m. f., (2) Zero shaft load, and (3) Zero resistance.

The first assumption is true in polyphase machines so far as the practical calculation of short-circuit currents is concerned. There are, of course, harmonics which exert appreciable influence in other problems of design, but little evidence of them is seen in oscillograms of short-circuit current.

Regarding the second assumption it has been pointed out in the preceding theory that the effect of load upon the initial value of short-circuit current is negligible.

The third assumption (zero resistance) does not appreciably affect the initial value of the short-circuit current in the ordinary machine, since the resistance is usually less than 3 or 4 per cent of the impedance. It does, however, affect the duration of the short-circuit current. Therefore, by neglecting r in the impedance and multiplying the resulting expression for current by $\epsilon^{-\frac{r}{L_o}t}$ the effect of resistance is, for practical purposes, taken into account.

Method of Attack

At the instant of short circuit the primary (stator) flux ceases to rotate since it must remain linked with the particular turns with which it was linked at the time the short circuit occurred. For the same reason, the secondary flux must continue to rotate. In a polyphase winding these fluxes are, at all times, supported by a resultant m. m. f. made up of ampere turns in each of the phases of the winding.

The problem at hand is to determine how the resultant m. m. f. in either member must adjust itself during rotation to maintain the constant value of flux. There are two sets of poles of practically the same magnitude, one stationary, the other rotating. The center lines of these poles afford references at which flux summations may be made involving equations including instantaneous values of m. m. f. For example, in Case I, where a polyphase short circuit is considered on a machine with a polyphase rotor, it is possible to sum up the following known values of fluxes in terms of known permeances and unknown instantaneous m. m. fs.

1. The total flux of the primary. The center line of this flux is, of course, the center line of the primary pole.
2. The primary flux in line with the secondary pole.
3. The total flux of the secondary.
4. The secondary flux in line with the primary pole.

In the case of a single-phase winding, since the current in all turns is in time phase, the direction of the resultant m. m. f., unlike the polyphase case, must be fixed by the position of the winding. Thus if both primary and secondary are single-phase only two equations are required. If one member is single-phase and the other polyphase three equations are required. In any case the reference lines are the same.

Notation

Φ_1 = flux linked with primary at instant of short circuit (stationary after short circuit).

Φ_2 = flux linked with secondary at instant of short circuit (rotating after short circuit).

F_m = magnetizing m. m. f. corresponding to the magnetizing current I_m in normal operation.

P_1 = permeance of primary = total primary flux per effective primary ampere turn (neglecting the effect of secondary).

P_2 = permeance of secondary = total secondary flux per effective secondary ampere turn (neglecting the effect of the primary).

P_m = permeance of mutual path = mutual flux per effective ampere turn of either primary or secondary.

ωt = electrical angle = $2 \pi f t$

f = electrical frequency

f_1 = total primary m. m. f. (at any time t) linking the primary flux and in line with the primary pole.

f_2 = total secondary m. m. f. (at any time t) linking the secondary flux and in line with the secondary pole.

f'_1 = the component of f_1 that is in line with f_2.

f'_2 = the component of f_2 that is in line with f_1.

I_m = magnetizing current at normal voltage.

I_n = normal rated current.

E = normal voltage per phase (*i. e.* per leg).

r_1 = resistance per phase of primary.

r_2 = resistance per phase of secondary reduced to primary terms.

r = resistance per phase = $r_1 + r_2$.

X = total leakage reactance per phase in primary terms.

X_p = per cent total reactance = $X I_n$ divided by the normal voltage per phase (expressed as a fraction $0.1 = 10$ per cent.)

L_0 = $X \div 2 \pi f$ = coefficient of total leakage induction.

i_1 = instantaneous primary current.

i_2 = instantaneous secondary current.

I_{01} = r. m. s. of initial value of a-c. component of primary short-circuit current.

I_{02} = r. m. s. of initial value of a-c. component of secondary short-circuit current.

Case 1. Polyphase Short Circuit

Polyphase primary, polyphase secondary.

At the instant of a no-load polyphase short circuit the total flux of the primary is,

$$\Phi_1 = F_m P_1 \tag{1}$$

and the total flux of the secondary is,

$$\Phi_2 = F_m P_m \tag{2}$$

Assuming zero resistance, Φ_1 and Φ_2 must remain constant and linked with the particular turns with which they were linked at the instant of short circuit.

At any time t after the short circuit, the rotor will have turned through the angle ωt. Then the primary flux in line with the rotor pole is,

$$\Phi_1 \cos \omega t = F_m P_1 \cos \omega t \tag{3}$$

and the secondary flux in line with the stator pole is,

$$\Phi_2 \cos \omega t = F_m P_m \cos \omega t \tag{4}$$

The equation for the total flux of the primary is,

$$f_1 P_1 + f^1{}_2 \, P_m = F_m P_1 \tag{5}$$

and for the secondary flux in line with the stator pole is,

$$f^1{}_2 P_2 + f_1 P_m = F_m P_m \cos \omega t \tag{6}$$

The equation for the total flux of the secondary is,

$$f_2 P_2 + f_1' P_m = F_m P_m \tag{7}$$

and for the primary flux in line with the rotor pole is,

$$f_1' P_1 + f_2 P_m = F_m P_1 \cos \omega t \quad (8)$$

Solving equations (5) and (6) for f_1 gives

$$f_1 = \frac{F_m}{\frac{P_1 P_2}{P_m^2} - 1} \left[\frac{P_1 P_2}{P_m^2} - \cos \omega t \right] \quad (9)$$

and solving (7) and (8) for f_2 gives

$$f_2 = F_m \frac{P_1}{P_m} \left[\frac{1 - \cos \omega t}{\frac{P_1 P_2}{P_m^2} - 1} \right] \quad (10)$$

The direct component of f_1 is,

$$f_{1d\text{-}c.} = \frac{F_m}{1 - \frac{P_m^2}{P_1 P_2}} \quad (11)$$

the a-c. component is,

$$f_{1a\text{-}c.} = - \frac{F_m}{\frac{P_1 P_2}{P_m^2} - 1} \cos \omega t \quad (12)$$

The direct component of f_2 is,

$$f_{2d\text{-}c.} = \frac{\frac{P_1}{P_m} F_m}{\frac{P_1 P_2}{P_m^2} - 1} \quad (13)$$

the a-c. component is,

$$f_{2a\text{-}c.} = - \frac{\frac{P_1}{P_m} F_m \cos \omega t}{\frac{P_1 P_2}{P_m^2} - 1} \quad (14)$$

Both f_1 and f_2 are a maximum at $\omega t = \pi$. At this instant f_1 is

$$f_1 \max = F_m \frac{\frac{P_1 P_2}{P_m^2} + 1}{\frac{P_1 P_2}{P_m^2} - 1} \quad (15)$$

and f_2 is

$$f_2 \max = F_m \frac{P_1}{P_m} \left[\frac{2}{\frac{P_1 P_2}{P_m^2} - 1} \right] \quad (16)$$

Thus, if $P_1 = P_2 = P$, and $P_m + P$ is greater than 0.9, the maximum values of f_1 and f_2 are equal within one-half of one per cent. Fig. 5 shows calculated curves for f_1 and f_2.

Before Case II is considered, equations (9) and (10) which give the m. m. f. of the primary and secondary for this case, will be expressed in terms of current instead of m. m. f. These equations involve the permeances P_1, P_2, and P_m, and the magnetizing m. m. f., F_m, which are related to the total per cent reactance X_p and normal current I_n as follows:

Let $P_1 - P_m$ = leakage flux of the primary per ampere turn,

and $P_2 - P_m$ = leakage flux of the secondary per secondary ampere turn.

Per cent reactance of primary

$$= \frac{\text{(leakage flux of primary at normal current)}}{\text{normal flux}}$$

but $F_m P_1$ = normal flux

and $F_n (P_1 - P_m)$ = leakage flux of primary at normal current.

Therefore, the per cent reactance of the primary is

$$\frac{F_n (P_1 - P_m)}{F_m P_1}$$

And since $\frac{F_n}{F_m} = \frac{I_n}{I_m}$

the per cent reactance of the primary is

$$\frac{I_n (P_1 - P_m)}{I_m P_1}$$

Assuming $P_1 = P_2 = P$, and that the primary and secondary ampere turns are equal, then the total reactance corresponding to normal current will be two times the primary reactance.

$$\text{Therefore, } X_p = \frac{2 I_n (P - P_m)}{I_m P} \quad (17)$$

The initial value of the short-circuit current is equal to normal rated current divided by the per cent total reactance.

$$\text{Therefore, } I_0 = \frac{I_n}{X_p}$$

And substituting the value of X_p from (17)

$$I_0 = \frac{I_m}{2\left(1 - \frac{P_m}{P}\right)} \quad (18)$$

$$\text{Since } \frac{F_m}{f_{1a\text{-}c.}} = \frac{\sqrt{2} I_m}{i_{1a\text{-}c.}}$$

Equation (12) may be rewritten in terms of current as follows:

$$i_{1a\text{-}c.} = \frac{\sqrt{2} I_m}{\frac{P_1 P_2}{P_m^2} - 1} \cos \omega t \quad (19)$$

In the ordinary machine P_m/P_1 is about 0.95, so I_0 may be substituted in (19) for

$$\frac{I_m}{\frac{P_1 P_2}{P_m^2} - 1}$$

without a significant error because the difference between I_0 from this expression (assuming $P_1 = P_2$) and I_0 from equation (18) is only 2 1/2 per cent. Likewise all the m. m. f. equations may be rewritten in terms of current as follows: from (11)

$$i_{1d\text{-}c.} = \sqrt{2}\, I_{01} \tag{20}$$

and from (12)

$$i_{1a\text{-}c.} = -\sqrt{2}\, I_{01} \cos \omega t \tag{21}$$

The total short-circuit current in the primary is the sum of the two components. That is,

$$i_1 = i_{1d\text{-}c.} + i_{1a\text{-}c.} = \sqrt{2}\, I_{01}\,(1 - \cos \omega\, t) \tag{22}$$

Also from (13)

$$i_{2d\text{-}c.} = \sqrt{2}\, I_{02} \tag{23}$$

And from (14)

$$i_{2a\text{-}c.} = -\sqrt{2}\, I_{02} \cos \omega\, t \tag{24}$$

And the total short-circuit current in the secondary is the sum of the two components.

$$i_1 = i_{2d\text{-}c.} + i_{2a\text{-}c.} = \sqrt{2}\, I_{02}\,(1 - \cos \omega\, t) \tag{25}$$

These equations were developed on the assumption of zero resistance. Multiplying (22) by

$$\epsilon^{-\frac{r_1}{L_0} t}$$

and (25) by

$$\epsilon^{-\frac{r_2}{L_0} t}$$

takes into account the effect of resistance. The final equations then become:

$$i_1 = \sqrt{2}\, I_{01}\, \epsilon^{-\frac{r_1}{L_0} t}\,(1 - \cos \omega\, t) \tag{26}$$

and $$i_2 = \sqrt{2}\, I_{02}\, \epsilon^{-\frac{r_2}{L_0} t}\,(1 - \cos \omega\, t) \tag{27}$$

Case II. Polyphase Short Circuit

Polyphase primary, one phase of secondary excited with direct current.

This case requires only three equations for the solution since the secondary is single-phase. The equations summing up the flux in the machine are as follows:

1. Total flux of the primary,
$$f_1 P_1 + f_2 P_m \cos \omega\, t = F_m P_m \tag{28}$$
2. Total flux of the secondary,
$$f_2 P_2 + f_1' P_m = F_m P_2 \tag{29}$$
3. Primary flux in line with the rotor pole,
$$f_1' P_1 + f_2 P_m = F_m P_m \cos \omega\, t \tag{30}$$

Solving equations (29) and (30) for f_2 gives

$$f_2 = F_m \frac{\frac{P_1 P_2}{P_m^2} - \cos \omega\, t}{\frac{P_1 P_2}{P_m^2} - 1} \tag{31}$$

Solving equations (28) and (31) for f_1 gives

$$f_1 = F_m \frac{P_m}{P_1}\left[1 - \frac{1}{\frac{P_1 P_2}{P_m^2} - 1}\left\{\frac{P_1 P_2}{P_m^2} \cos \omega\, t - 1/2\,(1 + \cos 2\, \omega\, t)\right\}\right] \tag{32}$$

Case III. Single-Phase Short Circuit

Polyphase induction motor or generator. It is assumed that the third line is opened at the instant the other two are short-circuited.

Let δ = angle between center line of flux and center line of short-circuited phases at the instant of short circuit.

The flux caught in the short-circuited phases is,

$$\Phi_1 \cos \delta = F_m P_1 \cos \delta$$

The flux in the rotor is,

$$\Phi_2 = F_m P_m$$

Summing up the flux as in the previous cases gives the equations necessary for the solution.

The total flux of the primary is,

$$f_1 P_1 + f_2' P_m = F_m P_1 \cos \delta \tag{33}$$

The total flux of the secondary is

$$f_1 P_m \cos \omega\, t + f_2 P_2 = F_m P_m \tag{34}$$

The secondary flux in line with the stator pole is

$$f_1 P_m + f_2' P_2 = F_m P_m \cos \omega\, t \tag{35}$$

Solving (33) and (35) for f_1 gives

$$f_1 = F_m \frac{\frac{P_1 P_2}{P_m^2} \cos \delta - \cos \omega\, t}{\frac{P_1 P_2}{P_m^2} - 1} \tag{36}$$

and solving (36) and (34) for f_2 gives

$$f_2 = F_m \frac{P_m}{P_2}\left[1 - \frac{1}{\frac{P_1 P_2}{P_m^2} - 1}\left\{\frac{P_1 P_2}{P_m^2} \cos \delta \cos \omega\, t - 1/2\,(1 + \cos 2\, \omega\, t)\right\}\right] \tag{37}$$

If the short circuit occurs at δ = 90 deg., that is, at maximum voltage, (36) becomes

$$f_1 = -F_m \frac{\cos \omega\, t}{\frac{P_1 P_2}{P_m^2} - 1} \tag{38}$$

and (37) becomes

$$f_2 = F_m \frac{P_m}{P_2}\left[1 - \frac{1}{\frac{P_1 P_2}{P_m^2} - 1}\right.$$

$$\left\{ - 1/2 \, (1 + \cos 2 \, \omega \, t) \right\} \Bigg] \qquad (39)$$

CASE IV. SINGLE-PHASE SHORT CIRCUIT

Single-Phase Stator, Single-Phase Rotor.

Let δ = angle between center line of stator pole and center line of rotor pole at the instant of short circuit.

The total flux of primary at the instant of short circuit is

$$\Phi_1 = F_m \, P_m \cos \delta$$

and the flux of secondary

$$\Phi_2 = F_m \, P_2$$

At any time after short circuit the primary flux is

$$f_1 \, P_1 + f_2 \, P_m \cos \omega t = F_m \, P_m \cos \delta \qquad (40)$$

and the secondary flux is

$$f_1 \, P_m \cos \omega \, t + f_2 \, P_2 = F_m \, P_2 \qquad (41)$$

Solving these equations for f_1 gives

$$f_1 = F_m \frac{P_2}{P_m} \; \frac{\cos \delta - \cos \omega \, t}{\dfrac{P_1 \, P_2}{P_m^2} - 1/2 \, (1 + \cos 2 \, \omega \, t)} \qquad (42)$$

Solving for f_2 gives

$$f_2 = F_m \frac{\dfrac{P_1 \, P_2}{P_m^2} - \cos \delta \cos \omega \, t}{\dfrac{P_1 \, P_2}{P_m^2} - 1/2 \, (1 + \cos 2 \, \omega \, t)} \qquad (43)$$

If the short circuit occurs at δ = 90 deg., that is maximum voltage, the equations become

$$f_1 = - F_m \frac{P_2}{P_m} \; \frac{\cos \omega \, t}{\dfrac{P_1 \, P_2}{P_m^2} - 1/2 \, (1 + \cos 2 \, \omega \, t)} \qquad (44)$$

and

$$f_2 = F_m \frac{1}{1 - 1/2 \, \dfrac{P_m^2}{P_1 \, P_2} \, (1 + \cos 2 \, \omega \, t)} \qquad (45)$$

FROM THE ANNUAL REPORT OF THE BUREAU OF STANDARDS

The year has seen the Bureau of Standards of the Department of Commerce, organization change from a war-time to a peace basis. Although the armistice began during the period covered by the previous annual report, many investigations inaugurated during the war naturally held over for several months.

During the past year the Bureau's cooperation with the industries has been particularly close. The inauguration of new lines of work which was given a great impetus during the war has affected nearly every American industry, and the Bureau has been able to be of considerable assistance to these manufacturers through the accurate scientific data which it is able to furnish as a result of its researches.

The testing work carried out during the year has in some cases been slightly less than during the war period but in general the volume of this work has not decreased to any extent, owing to the fact that while the amount of work for the military departments has been somewhat less, that for the industries has been very much greater. The total number of tests conducted during the year for the Government was 72,398, and the tests conducted for the public numbered 34,501 or a total number of all tests of 106,899.

During the year the Bureau's staff comprised 381 statutory employees and 600 engaged in research and investigations specially authorized by Congress. The turn-over in personnel during the year was quite large, and this is a problem still demanding solution. For accurate, scientific work, such as that conducted by the Bureau, it is essential that stability in the personnel be maintained, and the salaries paid to employees should be commensurate with those obtained in the industries or educational institutions.

The annual conference on weights and measures was held at the Bureau from May 24-27, and a number of important questions were discussed. The greatest interest was displayed in the papers presented and in the discussions and debates. Among the subjects of special interest were sales by net weight, standardization of various commodities in package form and proposed legislation in reference to installation of testing gasoline measuring pumps.

The work in connection with electrolysis and gas engineering has been actively prosecuted and has resulted in very large savings to numerous municipalities.

Maximum Allowable Working Voltages in Cables

BY CHARLES W. DAVIS and DONALD M. SIMONS

of the Standard Underground Cable Company.

In recent years there has been a marked tendency, temporarily interrupted by the war, to operate electric power cable at increasingly higher voltages. For these higher voltage cables, the electric stress, or voltage per unit thickness of insulation is much higher than for the lower voltage cables, because the limiting overall dimensions have necessitated a *reduction in the factor of safety,* partly compensated for by improvement in the qualities of the insulating materials. When cables of still higher voltages are manufactured, the voltage stresses in the insulation will undoubtedly be proportionally higher again.

It has long been believed that a controlling factor in cable design is the maximum stress occurring at the working voltage, and were it possible to make cable with a dielectric that is under all conditions absolutely homogeneous throughout and in perfect contact with the conductors and the sheath, it seems not unreasonable to believe that maximum stress might prove the most important factor in design. Even the slight lack of uniformity, particularly in three-core cables, of the types that are most in use today, tends to produce incipient failure at points of less stress due in some cases to unevenly distributed compound, or in others to the uneven distribution of ionizable voids. Thus, as pointed out by the writers elsewhere[1], it may actually prove to be the case that in commercial cables of today, the average stress or the stress in and near the filler spaces in triplex cables is of more importance than maximum stress. Nevertheless the maximum stress is one of the limiting criteria and its obvious importance as greater uniformity of insulation is obtainable, is sufficient excuse for further study of it.

It is believed that it will be of interest and value to determine the limits of cable design as influenced by this one factor. Even if the final solution of the problem should be based upon a compromise of many conflicting factors, it is undoubtedly a step forward to investigate thoroughly the effect of any one limiting feature.

It would be interesting to know in advance what the highest operating voltages of the future will be, for a given limiting outside diameter, on the assumption that a certain value of maximum voltage stress in the insulation is the limiting feature in cable design. If we assume any limiting value of maximum stress, and assume that cables in the future will not be made with larger outside diameters than at present seem practiable, it will be possible to calculate the limiting working voltages that may be applied, if we know how to calculate the stresses in triplex cables operating under three-phase voltage, and if we know what size of conductor will produce the minimum value of maximum stress at the surface of the conductor for a given core diameter (*i. e.* the diameter under the lead sheath). In this article we propose to discuss methods of calculating stresses in triplex cables, giving examples of the calculation by the method given by R. W. Atkinson[2], and then to obtain a solution for the size of conductor which will produce a minimum value of maximum stress for a given core diameter. These data having been obtained, it will be easy to determine the maximum possible operating voltages for given limits of stress and outside diameter. It will be shown later, for instance, that, for a cable of equal belt and conductor insulation thicknesses and three-inch core diameter, 25,600 volts is the maximum allowable working voltage, if it should be decided that 25 kv. per cm. is the highest permissible stress.

Calculation of Electrostatic Stress

The maximum stress in a single-conductor cable (occurring at the conductor surface) can be found by the usual formula

$$G = \frac{E}{r \times \log R/r}$$

where E equals the voltage between conductor and sheath, R equals the radius of the cable over its insulation, and r equals the radius of the conductor, the logarithm being the natural logarithm. This formula is rather awkward to handle when many cables being figured, due to the fact that it involves the use of logarithms. R. W. Atkinson[2] has given a curve for obtaining this stress without the use of logarithms. The curve is reproduced here in Curve A, Fig. 1, and its method of use is discussed in Appendix A hereto.

In the above mentioned article[2], information is given which satisfies the long felt need for a method of determining the stresses in three-conductor cables under three-phase voltage. Up to the time of publication of this article, no adequate and easily workable method of doing this was available to the public. The author, very considerably extending the work and refining the methods the present writers used in 1913 to determine the stress in three-conductor cables, has obtained an experimental solution of this problem and accurately checked his method on single-conductor cables by comparing the experimental values with the theoretical values, and also by measurement of stresses in actual three-conductor cables.

The results of these experiments show that for anything like usual values of belt and conductor

1. *Electric Journal,* July 1920, Davis & Simons, "Allowable Working Stresses in High-Voltage Electric Cables."

2. A. I. E. E. Proceedings. June 1919, R. W. Atkinson, "The Dieletric Field in Electric Power Cables."

insulation the maximum stress occurs at the surface of the conductor in a three-conductor cable, at the point nearest the center of the cable, *i. e.* at the point marked (a) in Fig. 2, and the value is very closely equal to the stress obtained from calculation on the assumption that it is equal to that in a single-conductor cable of the same size of conductor and with an insulation thickness equal to the distance between the con-

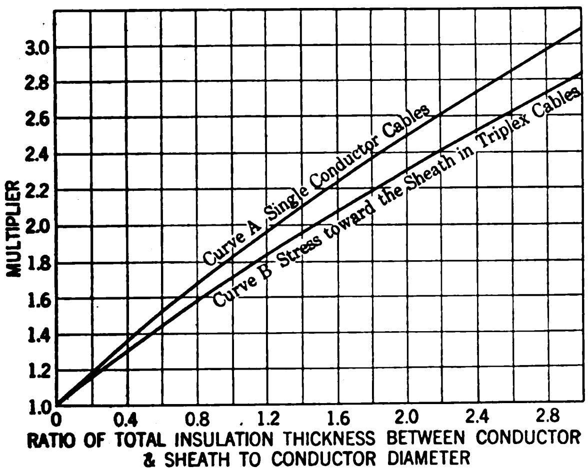

FIG. 1—ELECTROSTATIC STRESSES IN CABLES—RATIO OF MAXIMUM STRESS TO AVERAGE STRESS

(See "The Dielectric Field" by R. W. Atkinson, A. I. E. E. JOURNAL, June, 1919).

ductor surface and the center of the three-conductor cable. A small correction factor is involved dependent upon the relation between the conductor insulation and the conductor diameter. The value of this correction factor has been obtained experimentally for enough constructions of conductor size and insulation thickness to permit of the results being expressed in the form of an equation. Thus the calculation of maximum stress in a three-conductor cable resolves itself simply into the calculation of the stress in an equivalent single-conductor cable, with a final correction factor.

In applying this method it must be borne in mind that from the geometry of a three-conductor cable, the distance between the surface of a conductor and the center of the cable equals:

$$1.155\,t + 0.078\,d \qquad (1)$$

where t equals the conductor insulation thickness and d equals the conductor diameter. See Appendix B for an example.

As the correction factor is a small one, it is simpler to assume that it obeys a straight line law. The limiting values thus far obtained are as follows: For a ratio of conductor insulation thickness to conductor diameter equal to 0.288, the maximum stress in the equivalent single-conductor cable must be multiplied by 1.04 to obtain the actual maximum stress in the triplex cable considered; for a ratio of conductor insulation to conductor diameter equal to 0.625 the multiplier is 1.01. For values between these points, the multiplier can be found by interpolation, and when the ratio is greater than the larger one given the multiplier may be considered unity. We cannot safely go very far, however, in extrapolation below or above the ratios given, but this in most practical cases is obviously unimportant.

While the stress toward the center of the cable is the real maximum stress in all usual three-conductor cable formations, it is nevertheless a fact that, if the stress in the insulating material at the surface of the conductor is measured at all points around the entire circumference of the conductor, it will be discovered that the stress reaches a maximum value in two points, one being the point nearest the center or axis of the cable and the other that nearest the sheath of the cable. The former as above stated is the larger in all usual cases, although theoretically the stress toward the sheath might become larger if the thickness of the belt insulation were reduced far below the proportions necessary for mechanical strength.

It is often of interest to know what the stress is toward the sheath, both when the cable is operating under three-phase voltage and when it is being tested with single-phase voltage. This stress could be determined by Russell's formula for eccentric cylinders, if the stress at the surface of one conductor was not influenced by the presence of the other conductors. In point of fact it has been proved experimentally[2] not only that the presence of the other conductors has very little influence in cables of usual dimensions, but

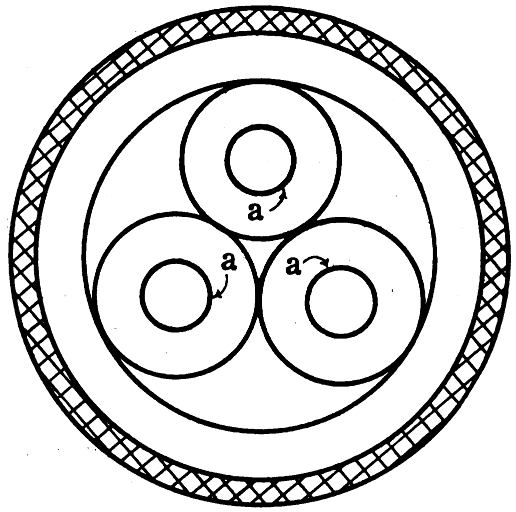

FIG. 2

(a) Shows location of maximum stress under three-phase voltage.

that the stress toward the sheath checks very closely with Russell's formula. The use of the formula is quite complicated, but the writer of the paper referred to has shown an easy solution giving results that are very closely identical with those given by Russell's formula. This is given in Curve B of Fig. 1. This curve is used in a manner similar to that used to find the stress in single-conductor cables, and an example is given in Appendix C.

The value of the stress at the surface of the conductor at the point nearest the sheath becomes of great importance in the case of an ungrounded neutral system in which one conductor has become grounded, the full line voltage being in that case impressed between each of the other two conductors and the lead sheath respectively. On account of the possibility of this occurrence, the belt insulation of cables used in a system with the neutral not grounded, is made considerably heavier than the belt of a cable in a grounded neutral system, usually being equal to the conductor insulation thickness. It must be borne in mind however, that in spite of the thicker belt of the cable in the ungrounded neutral system, the stress at the surface of the conductor toward the sheath in case one conductor should become grounded, is considerably higher than the stress toward the sheath in a grounded neutral system with the relatively thinner belt insulation. An example will make this clear. In a 00 triplex cable, insulated with 9/32 by 4/32 inches, at 25-kv. working pressure, the maximum stress, *i. e.* that toward the center of the cable, is 27.3 kv. per cm. and the stress toward the sheath is 23.5 kv. per cm., this cable being in operation in a grounded neutral system. In the case of an ungrounded neutral system, the make-up of the equivalent cable would undoubtedly be 00, insulated with 9/32 by 9/32 inches. Thus it would have 5/32 in. more belt insulation and therefore 5/32 in. more insulation between conductor and sheath. The maximum stress for this construction when the system is without grounds would be 27.5 kv. per cm. as before, and the stress toward the sheath would be 19.3 kv. per cm. If one conductor should be grounded, however, the full line voltage would be impressed between the other two conductors and the lead sheath, and the stress at the conductor surface toward the sheath would then become the real maximum stress and would be 33.3 kv. per cm. It is thus obvious that even with the heavy belt insulation ordinarily used in ungrounded neutral systems, the cable is under much more severe strain when one conductor becomes grounded, than is a cable with thinner belt insulation on a grounded neutral system.

All the stresses which have been calculated above, and also those which will be given later, are figured on the basis of smooth round conductors equal in diameter to the outside diameter of a strand of usual formation and of the size stated. The effect of the stranding on increasing the stress has therefore not been taken into consideration. The magnitude of the effect of the strands upon dielectric stress has been discussed by R. W. Atkinson[2] who gives four figures, showing that on the average the stress will be increased about 20 per cent from this cause. It remains for further experimentation to discover whether or not the greater stress of stranded cable as compared to solid conductors is of great importance, both when the cable is under continuous high stress and when it is subjected to momentary overvoltages. It would appear that in a homogeneous insulation, at least, there must be a considerable effect due to this additional stress.

Stress Tables

The calculations of the various stresses mentioned above are all more or less simple, but if it is desired to calculate the stresses in a large number of cables it becomes a rather laborious process. The stress Tables I, IA, II, III and IV have therefore been prepared.

TABLE I

MAXIMUM VOLTAGE STRESS IN TRIPLEX CABLES UNDER THREE-PHASE VOLTAGE

To obtain the maximum stress for a given cable, find the number in the following table corresponding to the size of conductor and conductor insulation thickness. Multiply the voltage in kv. between conductors by this number, and the product will be the maximum stress in kilovolts per centimeter.

Size A. W. G. strand	Diameter	Conductor insulation thickness in 32nd inches

50	9.16	1.29	1.22	1.17	1.13	1.09	1.05
70	10.82	1.22	1.16	1.09	1.05	1.01	0 98
95	12.60	1.15	1.10	1.03	1.00	0.96	0.92
120	14.23	1.10	1.05	0.99	0.96	0.92	0.88
150	15.90	1.06	1.01	0.95	0.92	0.88	0.85
185	17.67	1.02	0.97	0.92	0.88	0.85	0.81
240	20.13	0.97	0.92	0.87	0.84	0.81	0.78
310	22.88	0.93	0.89	0.83	0.81	0.77	0.75

In all cases the stress may be found by finding a number in the table corresponding to the size of conductor and insulation thickness of the cable in question, and multiplying this number by the line voltage in kilovolts.

Calculation of the Size of Conductor Giving a Minimum Value of Maximum Stress for a Triplex Cable of Given Core Diameter

It is a well-known fact that in single-conductor cables, for a given core diameter, (*i. e.* diameter over insulation), and voltage, the minimum value of the stress at the surface of the conductor will exist when the ratio of R/r equals 2.718 or the base of the natural system of logarithms. Let us consider the many arrangements of conductor size and insulation thickness that may be possible with a given core diameter for a three-conductor cable, and the stresses which will result therefrom. If we use very thick insulation for a given core diameter, we will be forced to employ a small conductor, which will produce a relatively high stress due to the extreme curvature of the conductor. On the other hand, if we use a large conductor diameter, we will have room for only a thin insulation and this will again produce a high stress. Between these two limits there exists one arrangement of conductor diameter and insulation thickness which will produce the minimum stress for a given core diameter. Let us consider a cable of three-inch core diameter whose conductor insulation and belt insulation are equal in thickness, and calculate the values of maximum stress at 20 kv. pressure for various

TABLE II
MAXIMUM VOLTAGE STRESS TOWARD THE SHEATH IN TRIPLEX CABLES

To obtain the maximum stress toward the sheath for a given cable, find the number in the following tables corresponding to the size of conductor and the total insulation between conductor and sheath. Multiply this number by the voltage between conductors in kv., and the product will be this maximum stress in kilovolts per centimeter.

Note that there are two points of maximum stress at the conductor surface in a triplex cable under three-phase voltage. The larger is usually toward the center, and can be obtained from other tables.

If the maximum stress under single-phase voltage is desired, (*i. e.*, three conductors vs. sheath, two conductors vs. other conductor and sheath etc.), this table may be used by multiplying the product by the square root of 3 (1.73). In this condition, the maximum stress in usual commercial cables occurs at the conductor surface toward the sheath.

TABLE IV

TABLE OF MAXIMUM STRESS IN SINGLE-CONDUCTOR CABLES

To obtain the stress for a given cable, find the number in the following table corresponding to its size of conductor and insulation thickness. Multiply the voltage in kv. by this number and the product will be the maximum voltage stress in kilovolts per centimeter.

Size A. W. G. strand	Diameter	Conductor insulation thickness in 32nd inches

conductor diameters, the insulation thickness of course varying so as to keep the three-inch core diameter. The results are shown graphically in Fig. 3 in which it may be seen that the conductor diameter for the minimum value of maximum stress is approximately 0.51 in. This could be done for any core diameter, and the corresponding curve plotted.

Let us now however, consider the general case, and obtain a mathematical solution of the minimum value of maximum stress for a given core diameter. This

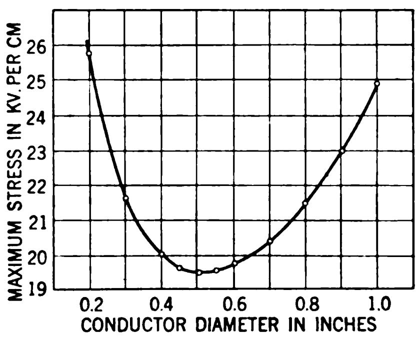

FIG. 3—CURVE SHOWING THE VARIATION OF MAXIMUM STRESS WITH SIZE OF CONDUCTOR FOR TRIPLEX CABLES OF A GIVEN CONSTANT CORE DIAMETER

This curve was calculated for a triplex cable of 3-in. core diameter at 20,000 volts pressure between conductors. The insulation to ground equals the insulation between conductors, and varies with the conductor diameter so as to keep the core diameter constant.

will vary according to what proportion of belt insulation is used. We will take first the case where the belt insulation equals the conductor insulation, in other words, where the insulation to ground equals the insulation between conductors, as would normally be used in ungrounded neutral systems. If a straight line curve is assumed for the final correction factor as suggested above, this factor may be expressed as equal to $\dfrac{1.066\,d - 0.089\,t}{d}$, using the two points given by Atkinson. The maximum stress at the conductor surface therefore may be expressed as follows:

$$G_{max} = \frac{E\left(\dfrac{1.066\,d - 0.089\,t}{d}\right)}{d/2\ .\ \log_e \Delta/d}$$

where G_{max} = the maximum stress at the conductor surface,

E = effective kilovolts between conductors and ground,

d = conductor diameter,

t = conductor insulation thickness = belt insulation thickness,

Δ = diameter over insulation of the "equivalent single-conductor cable."

Let D = diameter under lead sheath of triplex cable, *i. e.*, core diameter

and let

t' = insulation thickness of "equivalent single-conductor cable."

It is now desired to express G_{max} in terms of D and d

$t' = 1.155\,t + 0.078\,d$, from formula (1)

but $\Delta = 2\,t' + d$

$\therefore\ \Delta = 2.31\,t + 1.155\,d$

Now $D = 2.155\,(2\,t + d) + 2\,t = 6.31\,t + 2.155\,d$

(From the geometry of a triplex cable)

$\therefore\ \Delta = 0.3661\,D + 0.3661\,d$

$$\therefore\ G_{max} = \frac{2\,E\left(\dfrac{1.0964\,d - 0.01401\,D}{d}\right)}{d\log\left[\dfrac{0.3661\,(D+d)}{d}\right]}$$

$$\frac{\partial G}{\partial d} = \frac{\left(\dfrac{D}{D+d} \times \dfrac{1.0964\,d - 0.01401\,D}{d} - \dfrac{1.0964\,d - 0.02802\,D}{d} \times \log\left[\dfrac{0.3661\,(D+d)}{d}\right]\right)}{d^2\log^2\left[\dfrac{0.3661\,(D+d)}{d}\right]}$$

Letting $\dfrac{\partial G}{\partial d} = O$, in order to solve for the minimum value of G_{max}, we have

$$\log\left[\frac{0.3661\,(D+d)}{d}\right] - \frac{D}{D+d} \times \frac{d - 0.01278\,D}{d - 0.02556\,D} = O$$

which is satisfied when $D = 5.94\,d$. *Therefore, for three-conductor cables having equal belt and conductor insulation thicknesses, for a given core diameter, the minimum value of maximum stress will be attained when the conductor diameter equals the core diameter divided by* 5.94.

For a grounded neutral system it is not necessary to use the same amount of insulation between conductors and sheath as between conductors; common practise seems to indicate that for high-voltage grounded neutral systems the insulation to ground should not be less than 75 per cent of the insulation between conductors. With such cross-section there will usually be enough belt insulation to insure a reasonable factor of safety should some of the outer papers of the belt become damaged in the factory before lead covering, or be broken when the leaded cable is bent during reeling or during installation. For this case similar equations may be derived, and the most efficient cable, or the cable giving the minimum value of maximum stress is one where D equals $5.89 \times d$.

For low-voltage cables, where the stresses are usually low due to the relatively large thicknesses of insulation which have been considered good practise, some

cable makers use even slightly less insulation than this for the belt, and have insulation to ground as low as 70 per cent of the insulation between conductors. This is also the value given in British Engineering Standards Association in June 1919 for 11,000-volt paper cable and lower, and the thicknesses of conductor insulation recommended by these specifications are such as to bring the maximum stress fairly low, namely 24 kv. per cm. for 0.025 square inches, equivalent to about No. 4 A. W. G., when operating at 11 kv. three-phase. Even this is not the theoretical limit if we should attempt to design a cable whose stress toward the outside equals its maximum stress toward the center, but due to the fact that the belt is under severe mechanical strain and is likely to be broken and its insulating value impaired, it is probably not advisable to use less insulation to ground than 75 per cent and certainly not less than 70 per cent. For this amount of insulation, namely 70 per cent, we may also derive similar equations and obtain that, for minimum value of maximum stress, D equals $5.88 \times d$.

All the preceding facts and conclusions are based on three-conductor cables having round conductors. In case sector-shaped conductors are used, it is obvious that for a given core diameter we will have room for considerably more insulation and larger conductors. It is probable, however, that the increased curvature of the sector shape may increase the stress more rapidly than it would be diminished by the thicker possible insulation, and the result may very possibly be that sector cables will actually have lower limits of operating voltage for given limits of stress. A considerable amount of experimentation has been done on stresses in sector cables by the engineers of the company with which the writers are associated, and it is expected that the results of these experiments will be published in the near future. We may say for the present in regard to sector stresses that the stress may be either greater or less than the stress for a round conductor of the same area and with the same insulation thickness, depending upon the curvature of the sector. If the shape of the sector is such that the maximum stress is the same as for a circular conductor of the same cross-section, the saving in diameter will probably be about 5 per cent, or we may say that the limits of possible working voltage which we are about to give may be increased approximately 5 per cent if sector-shaped conductors are used.

It may be interesting to mention in passing certain results obtained by the writers experimentally in 1913, in connection with sector stresses. The stress in the inner third of the insulation around the conductor of a triplex cable was measured for various shapes of conductor. For the particular shape of sector used, it was found that the maximum stress for the sector-shaped conductor was 12.5 per cent greater than the maximum stress in the case of circular conductors, and the point of maximum stress for the sector conductor occurred at the two outer tips. Presumably if the stress had been measured at or near the conductor surface, this difference would have been greater.

There is of course another method of reducing the stresses in any type of cable, namely using successive layers of insulating materials of such permittivities that less voltage is impressed upon the inner layers of insulation. By this means, and with the available materials, we could possibly apply voltages of from 10 to 20 per cent higher than those about to be given, and still keep the maximum stress below the same limit.

MAXIMUM WORKING VOLTAGES FOR GIVEN LIMITS OF STRESS

As pointed out by the writers elsewhere[1], triplex paper cables are known to have operated for many years at stresses as high as *34.4 kv. per cm.*; rubber cables as high as *36.7 kv. per cm.*; and varnished cloth cables as high as *30.3 kv. per cm.* Since the present tendency appears to be to determine definitely upon some set limit of maximum stress as a matter of convenience in the design and rating of cables, it is of interest to select certain definite values such as 19.5 kv. per cm. as suggested by certain engineers[3], and say 25 kv. as suggested elsewhere by ourselves, and figure out the dimensions of the most efficient cables on these two assumptions.

If we know therefore what is the most efficient size of conductor for a given core diameter, and decide upon some maximum allowable stress, we may immediately determine the highest allowable working voltages for that core diameter. From the ratios calculated above, we have drawn curves for each type of triplex cable showing the minimum core diameter for the usual range of line voltages, if the stress is limited to certain values which we have taken arbitrarily as 19.5 and 25 kv. per cm. We have also calculated a similar curve for the form of cable suggested by Hochstadter commonly called type "H" cable, in which each single-conductor insulation is wrapped with copper foil, and the three cabled together without belt. In this case the usual single-conductor relation must hold that

$\frac{R}{r} = 2.718$ or e. For this cable the values of the curves were figured on the assumption that copper foil five mils in thickness was used. Fig. 4 shows one of these curves for a stress limit of 25 kv. per cm.

From these curves thus obtained, Table V has been prepared, showing the maximum voltages which may be employed for the usual sizes of duct if the stress is limited to these values. For each core diameter there is only one arrangement of size of conductor with corresponding insulation thickness which will give this stress, all other make-ups giving higher stresses. The

3. A .I. E. E. PROCEEDINGS, June 1919, Clark & Shanklin.

size of conductor and insulation thicknesses are also given in this table.

From Table V it can be seen that unless it be possible

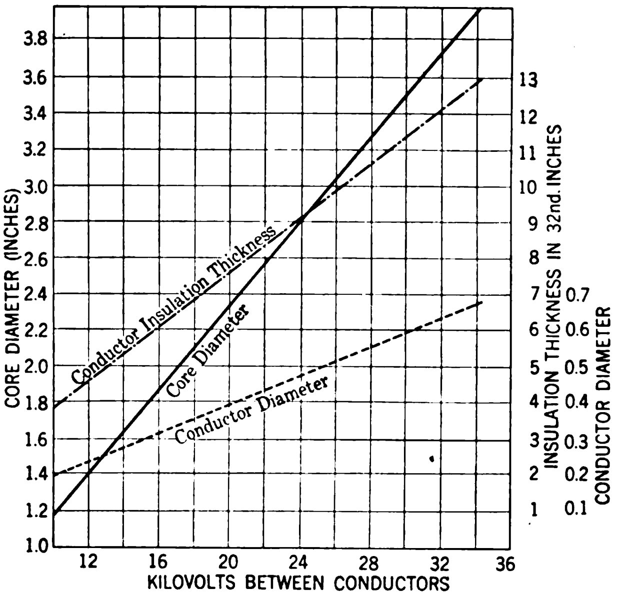

FIG. 4—CURVES SHOWING THE SMALLEST POSSIBLE TRIPLEX CABLES FOR THE USUAL RANGE OF HIGH-VOLTAGE CABLES, IF THE MAXIMUM STRESS IN THE INSULATION IS LIMITED TO 25KV. PER CM.

These curves are calculated for cables in which the belt insulation thickness is equal to the conductor insulation thickness.

Additional curves give for each voltage the size of conductor and insulation thickness which will produce the cable of minimum diameter.

to design cables to withstand higher stresses or to install larger ducts and manufacture and install larger cables, the highest possible three-phase working pressure for a triplex cable in an ungrounded neutral system is 23.3 kilovolts, if the maximum stress is limited to 19.5 kv. per cm., as suggested by certain experimenters, or 29.9 kilovolts if the maximum stress limit is 25 kv. per cm., at which stress many cables have operated successfully for as long as 20 years as pointed out by the writers elsewhere[1]. The above limits are for smooth round conductors, and are based solely on the assumption that maximum stress is the controlling factor rather than average stress, or stress in and near the filler spaces.

TABLE V

TABLE OF MAXIMUM WORKING VOLTAGES (EFFECTIVE VALUE) FOR TRIPLEX CABLES, IF THE MAXIMUM STRESS IS LIMITED TO CERTAIN VALUES

Width of duct. inches	Core diameter of cable in inches	Line kv. for stress of 19.5 per kv. per cm.	Line kv. for stress of 25 per kv. per cm.	Condr. diam. inches	Nearest size A.W.G.	Insulation thickness in 32nd in. Condr.	Insulation thickness in 32nd in. Belt	Type of cable
3	2.5	16.64	21.33	0.421	00	8.08	8.08	A
		18.57	23.80	0.425	"	9.56	4.78	B
		19.03	24.40	0.425	"	9.92	3.97	C

A. Insulation to ground equals insulation between conductors.
B. Insulation to ground is 75 per cent of insulation between conductors.
C. Insulation to ground is 70 per cent of insulation between conductors.
D. Type "H" Cable.

For a grounded neutral system, where the insulation to ground is cut down to 70 per cent of the insulation between conductors, the corresponding figures are 26.7 kv. for 19.5 kv. per cm. stress, and 34.2 kv. for 25 kv. per cm. It is therefore obvious that, assuming as before that maximum stress is the controlling factor,

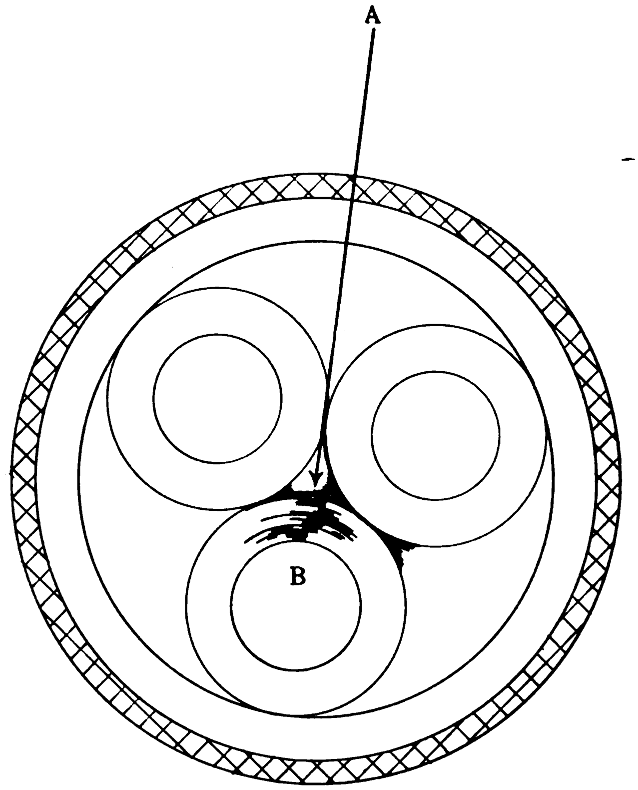

FIG. 5—EFFECT OF HIGH STRESS ON A TRIPLEX CABLE

three-conductor cables cannot operate at higher voltages than 34.2 kv. without exceeding the stress limits of 25 kv. per cm. unless we can manufacture larger cables and install them, or can develop insulations which can stand higher stresses.

The technical press has said more or less in recent years about charring of the center of triplex cables due to the combined heating effect of load current and high inherent dielectric loss in the insulation. Fig. 5 may be of interest as showing the appearance of a typical case of incipient failure of three-core cable operating without load but at such high three-phase voltage as would produce failure by ionization. The cable was subjected to a very high maximum stress for 126 hours while suspended in air at about 70 deg. fahr. The

cable was of mineral base compound and was of very low inherent dielectric loss even at high temperatures. It is believed that this drawing is of particular interest, since it shows not only the charring of the central filler, but also a case of incipient breakdown in the conductor insulation at the point of maximum stress. This drawing was built up very carefully, after the cable had been dissected layer by layer and drawings made of each layer, and it gives a very accurate representation of the amount of charring which was discovered.

It should be borne in mind, that the cable did not fail at this point, nor had any discharge taken place from A to B as there was no sign of puncture in any of the layers except one. It is worth noting that the charring, while perfectly discernible, was almost entirely confined to the surface of each layer of paper.

In the conclusion of their earlier paper [1], the authors stated that the data obtainable from actual operating cables would indicate that stresses as high as 40 kv. per cm. are permissible in single-conductor cables. There are many reasons why a single-conductor cable can stand a higher stress than a triplex cable. One of the chief reasons is that in a single-conductor cable the stresses are all normal to the surface of the paper layers, while in a triplex cable there are large tangential components of stress. One of the weakest points of a triplex cable is the filler space. While insulating materials have been greatly improved, the material available for use in the filler spaces has not kept pace with the rest of the insulation. Thus, at a relatively low stress at the surface of the conductor, the stress in and near the filler spaces may be far in excess of what the cable can stand. The single-conductor cable of course requires no fillers. Three-conductor cables made as suggested by Hochstadter, *i. e.* in which the insulation of each conductor is wrapped with copper foil, are essentially single-conductor cables insofar as the direction and magnitude of stresses are concerned, because the stresses are all radial and the filler spaces are unstressed; and it is reasonable to assume that they may operate at the same stresses which a single-conductor cable can stand. Besides, such cables can be operated at an even higher dielectric loss and higher current density than the ordinary three-core cable, due to the fact that the copper foil will conduct the heat away from the danger zone, namely the center of the cable. We may assume then, that this type of cable will eventually operate successfully for a long period of time at stresses in the neighborhood of 30 or 40 kv. per cm. or higher, since even three-conductor cables of the ordinary type have operated for years at values approximating those figures. In this case calculation shows that for 40 kv. per cm. stress, the maximum line voltages possible for three-conductor Type "H" cable are 37.3 kv. for 2½-inch core diameter, 44.8 kv. for 3-inch core diameter, and 52.3 kv. for 3½-inch core diameter.

Conclusions

It may be reasonably concluded from the limits shown in this article that for the high-voltage cables of the future, the ordinary three-core form of cable will be used as heretofore up to 30,000 volts, except where replaced by cable of higher efficiency; type "H" cable on account of its high carrying capacity, and high permissible working stress, from a few kilovolts up to 50,000 volts; and three single-conductor cables with conductors made with a hollow fibre core to increase the conductor diameter, for 50,000 volts and above. Three single-conductor cables could of course be used at lower ranges than this, but due to the difficulties of induced sheath currents and voltages and their higher cost, they would probably not be good economy until the higher voltage limit is reached, unless such large amounts of power are involved, as would require more than three triplex cables of the maximum size considered practical.

We desire to express our thanks to Mr. R. W. Atkinson for his suggestions and assistance in preparing the text.

APPENDIX A

Maximum Stress in Single-Conductor Cables

Let us find the stress in a 0000 strand single-conductor cable insulated with a thickness of 11/32 in. and 13,200 volts pressure. The diameter of a 0000 strand conductor equals 0.528 in., and 11/32 in. equals 0.3438 in. The ratio of conductor insulation thickness to conductor diameter therefore equals 0.651. The ordinate corresponding to this value in Curve A, Fig. 1 is 0.156. The average stress in this cable equals

$$\frac{13.2}{2.54 \times 0.3438} = 15.12 \text{ kv. per cm.}$$

15.12×0.156 equals 23.6 kv. per cm. maximum stress.

APPENDIX B

Maximum Stress in Triplex Cables

The maximum stress in a triplex cable occurs at the surface of the conductor at the point nearest the center or axis of the cable. Let us calculate the maximum stress in a three-conductor cable, 0000 strand, insulated with 9/32-in. insulation on each conductor and 9/32-in. belt, at 25,000 volts working pressure. Note that the maximum stress occurs toward the center of the cable, and is practically independent of the belt thickness. The diameter of a 0000 A. W. G. strand conductor equals 0.528 in., and 9/32 in. equals 0.281 in. Applying formula (1), we obtain 0.366 as the distance between the conductor surface and the center of the cable. As stated in the body of the article the maximum stress of the triplex cable is equal to the maximum stress in a single-conductor cable whose conductor diameter is the same as that of the triplex conductor and whose insulation thickness is equal to

the distance between the surface of the conductor and the center of the triplex cable, this value of stress thus obtained being mutiplied by a final correction factor. We must therefore determine the maximum stress in a single-conductor cable whose conductor diameter is 0.528 in., and whose insulation thickness is 0.366 in. This can be done by the usual formula or more conveniently by Curve *A* in Fig. 1. Choosing the latter method, the ratio of conductor insulation thickness to conductor diameter,

$$\frac{0.366}{0.528} = 0.693$$

The ordinate of Curve *A*, Fig. 1, corresponding to this, equals 1.592. The average stress of this insulation equals

$$\frac{25 \text{ kv.}}{\sqrt{3} \times 2.54 \times 0.366} = 15.5 \text{ kv. per cm.}$$

The maximum stress, therefore, equals

$$15.5 \times 1.592 = 24.7 \text{ kv. per cm.}$$

As mentioned above, however, there is a final correction factor to this value, depending upon the ratio of the *actual* conductor insulation thickness and conductor diameter, which ratio in this case,

$$\frac{0.281}{0.528}, \text{ equals } 0.532.$$

Interpolating between the values of the correction factor in the body of the article, we find that for this ratio the correction factor equals 1.02. The maximum stress in the triplex cable therefore is 1.02 × 24.7, which equals 25.2 kv. per cm.

APPENDIX C

Stress toward the Sheath in Triplex Cables

As an example let us find the stress at that portion of the surface of the conductor which is toward the sheath, in the triplex cable whose maximum stress was calculated in Appendix B, namely 0000 A. W. G. insulated with 9/32 in. on each conductor and 9/32-in. belt. The total insulation between conductors and ground equals 18/32 or 0.5625 in. The ratio of total insulation thickness to conductor diameter,

$$\frac{0.5625}{0.528} = 1.065.$$

The ordinate of Curve *B*, Fig. 1, corresponding to this value equals 1.745. The average stress is

$$\frac{25 \text{ kilovolts}}{\sqrt{3} \times 2.54 \times 0.5625} = 10.1 \text{ kv. per cm.}$$

This stress therefore equals

$$10.1 \times 1.745 = 17.6 \text{ kv. per cm.}$$

NEW ZEALANDS TELEGRAPH SERVICE

New Zealand is giving the rest of the world a good race in the perfection of its telephone and telegraph systems. Mr. E. A. Shrimpton, M. I. E. E., Permanent Chief Engineer of the Telegraph and Telephone Department of states that at the present time there are 85,000 telephones in use in New Zealand, an average of one to every sixteen inhabitants. Subscription to the phone system has never been solicited, a fact which makes the figures more to be wondered at.

The little island outpost of the British Empire takes particular pride in the fact that it has developed its lines of communication to such an extent while the British Isles can only boast of one telephone to about every forty-seven persons. Telephone rates in New Zealand have been increased this year without in any way decreasing the demands of new subscribers.

In an interview at the offices of the Western Electric Co., Mr. Shrimpton gave an interesting history of the development of the lines of communication in New Zealand. The first telephone exchange was erected at Christ Church only in 1880 yet today there are 400 exchanges in a country of only 1,100,000 people. There is not a single spot in New Zealand where the pedestrians cannot find a telephone line. There has even been a line to The Hermitage at the peak of New Zealand's loftiest mountain, nuch to the regret of the tired business men who had been accustomed to flee there to escape the humdrum of office life.

New Zealand has sent Mr. Shrimpton to the United States to investigate the latest developments in telephone and telegraph apparatus. In 1911 the new automatic exchange system was introduced into his department. Since the war 23 rotary automatic exchanges have been or will be put into use in New Zealand.

The New Zealanders are said to be the greatest telegraph users in the world. During 1919 their telegraph lines carried over 14,000,000 messages, a far higher average than prevailed in the United States. At the present time New Zealand has supervision over all the British wireless stations in the Pacific. In addition to five in its own territory, Mr. Shrimpton's department controls the stations at Chatham Island, Apia and Raratonga. Before the war the station at Apia belonged to Germany. It is over 1800 miles away from headquarters at New Zealand.

On Electrostatic Transformers and Coupling Coefficients.*

BY F. C. BLAKE

Physical Laboratory, The Ohio State University, Columbus, Ohio.

Starting from the experimentally determined fact that the capacity of an air condenser is independent of the frequency of electrical oscillation, it is shown by means of Lord Rayleigh's equations for the mutual reaction between two circuits each having inductance, resistance, and capacity, that for high-frequency conditions when the resistance is negligible compared to the reactance, the capacity reaction between the two circuits can be expressed best in terms of elastances. Definitions are given for self and mutual elastances as well as for self and mutual capacitances and the definitions are tested by our knowledge of spherical condensers. The coefficient of elastic coupling is shown to be the ratio between the mutual elastance and the square root of the product of the two self elastances, the analogy with the coefficient of inductive coupling being exact. The coefficient of capacitive coupling between two circuits each having capacity with a capacity in the branch common to both is shown to be a limiting case of the coefficient of elastic coupling, and thereby a condenser of the ordinary or close form is shown to be an electrostatic transformer with a coupling coefficient of unity. The true relationship between Maxwell's coefficients of capacity and the elastances or capacitances is pointed out in the case of the spherical condenser. The ideas developed are applied to the thermionic tube and thereby the behavior of the ultraudion and the experiments of Van der Pol are readily explained. Attention is called to the alternative view of the behavior of condensers toward alternating currents, viz., instead of being paths of low impedance, they are paths of ready yielding or low stiffness or elastance, as suggested by Heaviside and by Karapetoff.

In a paper presented before the American Physical Society in November 1919, the writer was able experimentally to verify the equations developed by Lord Rayleigh[1] for the reaction of one circuit upon another, each circuit having both kinetic and potential energy as well as dissipation, *i. e.*, inductance, capacity and resistance. If L_{11}, L_{22} and L_{12} are the self and mutual inductances, E_{11}, E_{22} and E_{12} the self and mutual elastances, (see below) R_{11}, R_{22} and R_{12} the self and mutual resistances, and p the generalized frequency, then the effective elastance, E_e and the effective resistance, R_e are given by the equations:

$$E_e = E_{11} - p^2 L_{11} - \frac{(E_{12} - p^2 L_{12})^2}{E_{22} - p^2 L_{22}} + \frac{p^2 [R_{12}(E_{22} - p^2 L_{22}) - R_{22}(E_{12} - p^2 L_{12})]^2}{(E_{22} - p^2 L_{22})[(E_{22} - p^2 L_{22})^2 + p^2 R_{22}^2]}, \quad (1)$$

$$R_e = R_{11} - R_{12}^2/R_{22} + \frac{[R_{12}(E_{22} - p^2 L_{22}) - R_{22}(E_{12} - p^2 L_{12})]^2}{R_{22}[(E_{22} - p^2 L_{22})^2 + p^2 R_{22}^2]}. \quad (2)$$

The verification was accomplished by working with Lecher and receiver systems, thus using short electric waves. For such systems the distributed capacity of the Lecher wires has to be taken into account as well as the capacities of the condensers. Thus the generalized formula for the discharge of a condenser was found to hold, *viz.*,

$$\frac{2\pi l}{\lambda} \tan \frac{2\pi l}{\lambda} = \frac{k l}{K}, \quad (3)$$

where l is the length of the Lecher circuit measured from the exploring bridge up to the condenser, λ the wave-length of the harmonic under consideration, K the capacity of the condenser and k the capacity per unit length of the Lecher wires. In such systems equation (3) takes the place of Lord Kelvin's equation for the discharge of a condenser, *viz.*,

$$p^2 L K - 1 = 0. \quad (4)$$

In equations (1) and (2) all the self coefficients were determined from geometrical considerations, the mutual coefficients being determined from the experimental observations. For instance, E_{11} is the reciprocal of the capacity of the plate attached to the Lecher circuit when it exists *alone in space*, E_{22} being the reciprocal of the capacity of the plate attached to the receiver circuit *under the same conditions*. E_{12} on the other hand was determined by noting the difference in frequency of the two fundamental tones as the coupling between Lecher and receiver circuits was tightened. Similarly, L_{11} is the self inductance of half of the Lecher circuit and L_{22} is the self inductance of the receiver circuit. Substituting these values of L and E in equation (3) one can find the natural frequency n of each circuit *when alone in space*. It is, of course, this natural frequency n that must be used in equations (1) and (2) for either primary (Lecher) or secondary (receiver) circuit when existing separately. Hence, equations (1) and (2) become

$$E_e = E_{11} - n^2 L_{11} - \frac{(E_{12} - p^2 L_{12})^2}{E_{22} - n^2 L_{22}} + \frac{p^2 [R_{12}(E_{22} - n^2 L_{22}) - R_{22}(E_{12} - p^2 L_{12})]^2}{(E_{22} - n^2 L_{22})[(E_{22} - n^2 L_{22})^2 + p^2 R_{22}^2]}, \quad (5)$$

$$R_e = R_{11} - \frac{R_{12}^2}{R_{22}} + \frac{[R_{12}(E_{22} - n^2 L_{22}) - R_{22}(E_{12} - p^2 L_{12})]^2}{R_{22}[(E_{22} - n^2 L_{22})^2 + p^2 R_{22}^2]}. \quad (6)$$

*Read before the American Physical Society, Feb. 28, 1920.

1. *Phil. Mag.* XXI. pp. 369-381, 1886; Scientific Papers, Vol. II p. 484.

By causing the Lecher and receiver circuits to approach each other both E_{12} and R_{12} were made to vary, the system being so disposed that L_{12} was practically zero always. Naturally E_{12} would be expected to increase and R_{12} to decrease as the circuits approached each other. This was borne out by observation. Calculation really showed that for the frequencies used ($n > 10^8$) the last term in (**5**) was negligible compared to the other terms so long as R_{12} was small. Because the currents are of such high frequency $p^2 R_{22}^2$ is entirely negligible compared to $(E_{22} - n^2 L_{22})^2$ and (**5**) and (**6**) reduce to

$$E_e = E_{11} - n^2 L_{11} - \frac{(E_{12} - p^2 L_{12})^2}{E_{22} - n^2 L_{22}} + \frac{p^2 [R_{12}(E_{22} - n^2 L_{22}) - R_{22}(E_{12} - p^2 L_{12})]^2}{(E_{22} - n^2 L_{22})^3}, \quad (7)$$

$$R_e = R_{11} - \frac{R^2_{12}}{R_{22}} + \frac{[R_{12}(E_{22} - n^2 L_{22}) - R_{22}(E_{12} - p^2 L_{12})]^2}{R_{22}(E_{22} - n^2 L_{22})^2}. \quad (8)$$

For distances between the circuits less than 15 per cent of the diameter of the capacity plates it was found that R_{12} was practically equal to zero and (**7**) reduced in this case to

$$E_e = E_{11} - n^2 L_{11} - \frac{(E_{12} - p^2 L_{12})^2}{E_{22} - n^2 L_{22}}.$$

For electrostatic (elastic) coupling between the circuits L_{12} is zero and we have

$$E_e = E_{11} - n^2 L_{11} - \frac{E_{12}^2}{E_{22} - n^2 L_{22}}. \quad (9)$$

Thus for radio frequency currents the effective elastance of a circuit is apparently a function not only of its own elastance, the elastance of a neighboring circuit and their mutual elastance but also of their self and mutual inductances. If now the self (C_{11} and C_{22}) and mutual (C_{12}) capacitances of the conductors forming the condensers between the Lecher and receiver circuits be *defined* as the reciprocals of the self and mutual elastances of these conductors and if C_e be the effective capacity of the primary circuit, then

$$C_e = C_{11} \frac{1}{(1 - n^2 L_{11} C_{11}) - \frac{C_{11} C_{22}}{C_{12}^2} \cdot \frac{1}{1 - n^2 L_{22} C_{22}}}. \quad (10)$$

If in (**9**) the inductances L_{11} and L_{22} are negligible or zero we have

$$E_e = E_{11} - \frac{E_{12}^2}{E_{22}}, \quad (11)$$

which is, of course, the effective capacity of a conductor in the presence of another conductor for high-frequency currents. It is to be noted that equation (**11**) is the exact analog for reacting systems having stiffness or elastance, of the well-known equation for inductively reacting systems, *viz.*,

$$L_e = L_{11} - \frac{L_{12}^2}{L_{22}}. \quad (12)$$

Now inertia (inductance) is a measure of the resistance a body offers to a change in its condition of motion, and stiffness (elastance) is a measure of the resistance an elastic body offers to its instantaneous condition of vibratory motion. If in (**12**) the coefficient of inductive coupling k is equal to $\frac{L_{12}}{\sqrt{L_{11} L_{22}}}$ as is well-known, then (**12**) may be written $L_e = L_{11}(1 - k^2)$. (**13**) So also the coefficient of elastic coupling k is equal to $\frac{E_{12}}{\sqrt{E_{11} E_{22}}}$ and (**11**) may be written

$$E_e = E_{11}(1 - k^2) \quad (14)$$

From the definitions of self and mutual capacitances given it is manifest that if in (**10**) we take L_{11} and L_{22} each zero the effective capacity of the primary circuit becomes

$$C_e = C_{11} \frac{C_{12}^2}{C_{12}^2 - C_{11} C_{22}}, \quad (15)$$

and if we substitute k^2 for $\frac{C_{11} C_{22}}{C_{12}^2}$ (**15**) reduces to

$$C_e = \frac{C_{11}}{1 - k^2}, \quad (16)$$

which obviously may be made as large as we please by making k approach unity more and more nearly. This accounts for the capacity of a condenser being so enormous compared to the capacities of its component conductors when far removed from each other.

Just as in (**13**) the maximum value of k is unity so the maximum value of k in (**14**) is also unity. Thus just as the effective inductance of a coil is decreased by the presence of a second coil so also the effective elastance of a conductor is decreased by the presence of a second conductor.

In discussing two mutually reacting inductive circuits Lord Rayleigh derives the equation

$$L_e = L_{11} - \frac{L_{12}^2}{L_{22}} + \frac{(L_{12} R_{22} - L_{22} R_{12})^2}{L_{22}(p^2 L_{22}^2 + R_{22}^2)}, \quad (17)$$

in which the second fraction is positive and with increasing p^2 continually diminishes. Hence, Lord Rayleigh remarks that L_e continually diminishes with increasing frequency tending ultimately to the minimum corresponding to the disappearance of the dissipative terms. At radio frequencies this minimum has been reached and (**17**) then reduces to (**12**). If in

(**5**) and (**6**) we have two mutually reacting elastic circuits the, taking $L_{12} = 0$, (**5**) and (**6**) become

$$E_e = E_{11} - \frac{E_{12}^2}{E_{22}} + \frac{p^2 (R_{12} E_{22} - R_{22} E_{12})^2}{E_{22} (E_{22}^2 + p^2 R_{22}^2)} \quad (18)$$

$$R_e = R_{11} - \frac{R_{12}^2}{R_{22}} + \frac{(R_{12} E_{22} - R_{22} E_{12})^2}{R_{22} (E_{22}^2 + p^2 R_{22}^2)}, \quad (19)$$

and Lord Rayleigh remarks for this case of the discharge of condensers through high resistances that as p^2 increases the elastance increases and the resistance diminishes. But here again at radio frequencies the resistance terms disappear compared to the reactance terms unless unusually fine discharge wires are used and accordingly the third term on the right-hand side of (**18**) becomes negligible and again the minimum given by the first two terms has been reached and (**18**) reduces to (**11**). In other words, beyond a certain frequency the effective elastance, instead of increasing with increasing frequency as Lord Rayleigh says, will in general decrease owing to the ratio of the reactance to the resistance steadily mounting in value, the effective elastance ultimately reaching the minimum given by the disappearance of the dissipative terms.

Comparison of (**11**) with (**12**) and of (**13**) with (**14**) leads to the following further considerations. Given two inductive coils *each on closed circuit.* Starting with them infinitely removed from each other, by causing the distance between them to decrease from infinity to zero the coefficient of inductive coupling is increased from zero to unity. When alone in space the self inductance of each coil is the magnetic flux from it (through it) when unit current is passing in it. So also for any given distance between the two coils the mutual inductance is the magnetic flux through one coil due to unit current in the other. Similarly, given two conductors infinitely removed from each other to start with. As the distance between them is decreased from infinity to zero the coefficient of elastic coupling is increased from zero to unity. When each conductor is alone in space its self elastance is the electric flux from it due to unit charge upon it. So also for any given distance between the two conductors their mutual elastance is the electric flux ending on one conductor B due to unit charge on the other A provided the conductor B has the induced charge of like sign as that on A removed by being "earthed."

That the proviso in this definition of mutual elastance is necessary is easily shown from a consideration of the spherical condenser. It has been shown (equation **15**) that the theoretical capacity of a condenser is the reciprocal of the effective elastance, E_e, where E_e fulfills equation (**11**). Now it is well-known that if a and b are the radii of the inner and outer spheres of a spherical condenser the capacity of the condenser when the outer sphere is earthed is $\frac{a\,b}{b-a}$ and when the inner sphere is earthed its capacity is $\frac{b^2}{b-a}$. If the inner sphere is taken as the first conductor and the outer sphere as the second then we have $E_{11} = 1/a$ and $E_{22} = 1/b$ whence

$$\frac{b-a}{a\,b} = \frac{1}{a} (1 - a\,b\,E_{12}^2), \quad (20)$$

giving $E_{12} = 1/b$ and consequently $C_{12} = b$. Thus $k = \sqrt{a/b}$ and when $b = \infty$ $k = 0$ and for $b = a$, $k = 1$ as it should. If the conductors be reversed we get

$$\frac{b-a}{b^2} = \frac{1}{b} (1 - a\,b\,E_{12}^2),$$

giving $E_{12} = 1/b$ as before. The fact that for the spherical condenser $E_{12} = E_{22}$ testifies most strikingly to one of its fundamental properties, *viz.*, that all the lines of force leaving the inner sphere end on the inner surface of the outer sphere.

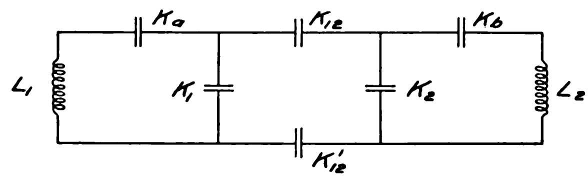

FIG. 1

It is customary to define the capacity of a condenser as the ratio of the charge on one of the conductors forming the condenser to the difference of potential between the conductors, all the lines of electric flux starting from one conductor ending on the other. The last phrase of the previous sentence shows that such a condenser *is to be regarded as an electrostatic transformer whose coefficient of elastic coupling is unity.*

It will now be shown that the coefficient of elastic coupling as defined in this paper, *viz.*, the ratio of the mutual elastance between the two component conductors of a condenser divided by the square root of the product of their self elastances enables one at once to derive the coefficient of electrostatic coupling between two circuits in each of which there is a condenser with a third condenser in the branch common to both circuits.

E. Bellini[2] has shown that the coefficient k of what he calls the electric coupling fulfills for the most general case (see Fig. 1) the equation

$$k = \frac{K_t}{K_1 K_2} \sqrt{G_1 G_2}, \quad (21)$$

2. *La Lumière Electrique*, 2, 33, p. 241, 1916.

where

$$\frac{1}{K_t} = \frac{1}{K_1} + \frac{1}{K_2} + \frac{1}{K_{12}} + \frac{1}{K_{12}'},$$

$$\frac{1}{G_1} = \frac{1}{K_a} + \frac{1}{K_1} - \frac{K_t}{K_1^2},$$

and

$$\frac{1}{G_2} = \frac{1}{K_b} + \frac{1}{K_2} - \frac{K_t}{K_2^2}.$$

By taking

$$K_{12} = K_{12}' = \infty, \; k \text{ reduces to } \frac{\sqrt{K_{11} K_{22}}}{K_c} \tag{22}$$

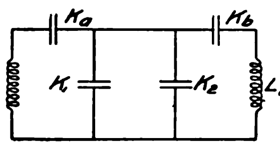

FIG. 2A

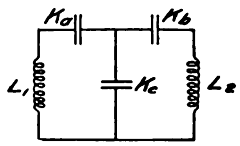

FIG. 2B

where

$$\frac{1}{K_{11}} = \frac{1}{K_a} + \frac{1}{K_c} \text{ and } \frac{1}{K_{22}} = \frac{1}{K_b} + \frac{1}{K_c}$$

and

$$K_c = K_1 + K_2.$$

In this case Fig. 1 obviously reduces to Fig. 2A, and Professor G. W. O. Howe[3] has shown that Fig. 2A reduces to Fig. 2B wherein

$$K_c = K_1 + K_2$$

Consider now Figs. 3 and 4.

The two figures are exactly alike except that in Fig. 3 the reaction is an inertia reaction while in Fig. 4, it is an elastic reaction, hence the conductors E_1 and E_2 are represented as spiral springs while the L's may

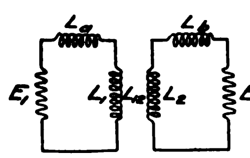

FIG. 3

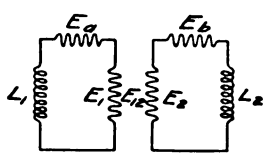

FIG. 4

be thought of as masses if one chooses. Plainly the coefficient of magnetic coupling k in Fig. 3 is given by

$$k^2 = \frac{L_{12}^2}{L_{11} L_{22}}$$

where $L_{11} = L_1 + L_a$ and $L_{22} = L_2 + L_b$

Equally plainly in Fig. 4 the coefficient of elastic coupling k is given by

$$k^2 = \frac{E_{12}^2}{E_{11} E_{22}}$$

where $E_{11} = E_1 + E_a$ and $E_{22} = E_2 + E_b$

3. *Electrical World*, 68, p. 368, 1916.

Accordingly remembering the reciprocal relationship between elastances and capacitances we have

$$k^2 = \frac{E_{12}^2}{E_{11} E_{22}} = \frac{\frac{1}{C_{12}^2}}{\frac{1}{C_{11}} \frac{1}{C_{22}}}$$

$$= \frac{E_{12}^2}{(E_a + E_1)(E_b + E_2)}$$

$$\frac{\frac{1}{C_{12}^2}}{\left(\frac{1}{C_a} + \frac{1}{C_1}\right)\left(\frac{1}{C_b} + \frac{1}{C_2}\right)} \tag{23}$$

If one redraws Fig. 2B as Fig. 5 by omitting the inductances it is readily seen that the system consists of four circuits, two of which are exact counterparts of the other two. Viewed from the standpoint of a Lecher system, circuits 1 and 2 of Fig. 5 are equal, as

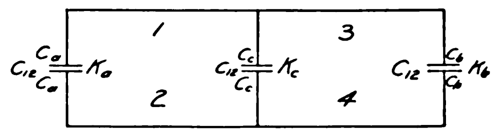

FIG. 5

are also circuits 3 and 4. But by comparing Figs. 4 and 5 we see at once that on account of (**16**)

$$k_a = \frac{C_a}{1 - k^2}, \; k_c = \frac{C_c}{1 - k^2}, \text{ and } k_b = \frac{C_b}{1 - k^2}.$$

Now E_1 of Fig. 4 is $\frac{1}{C_c}$ of Fig. 5 as is also E_2 of Fig. 4. Whence

$$k^2 = (1 - k^2)^2 \frac{\frac{1}{C_{12}^2}}{\left(\frac{1}{k_a} + \frac{1}{k_c}\right)\left(\frac{1}{k_b} + \frac{1}{k_c}\right)}$$

$$k = (1 - k^2) \frac{\frac{1}{C_{12}}}{\sqrt{\left(\frac{1}{k_a} + \frac{1}{k_c}\right)\left(\frac{1}{k_b} + \frac{1}{k_c}\right)}} \tag{24}$$

But k_c (Fig. 5) $= \frac{C_c}{1 - k^2}$

whence

$$k = \frac{C_c}{C_{12}} \frac{\frac{1}{k_c}}{\sqrt{\left(\frac{1}{k_a} + \frac{1}{k_c}\right)\left(\frac{1}{k_b} + \frac{1}{k_c}\right)}}$$

$$= \frac{C_c}{C_{12}} \cdot \frac{\sqrt{K_{11} K_{22}}}{k_c},$$

which is equation (**22**) provided $\frac{C_c}{C_{12}}$ may be taken equal to unity, a permissible thing to do for ordinary condensers, as has been shown. Thus it is proved that the coefficient of electric or electrostatic coupling is identical for very close couplings with the coefficient of elastic coupling. It is thus seen that just as the auto transformer is the limiting case of the customary transformer (See Circular No. 74, B. S. p. 49, Figs. 33A and B) so also the auto condenser transformer (Fig. 33C of B. S. 74 or Fig. 2 of this paper) is the limiting case of Fig. 4 of this paper. W. O. Lytle has recently[4] verified experimentally equation (**22**).

Several practical consequences follow from the above considerations. This paper gives, as it were, the modus operandi of the capacity coupling of a triode valve. It explains for instance the regenerative action of deForest's ultraudion connection,[5] for there is elastic coupling between the grid and plate and also between the plate and filament of a triode valve as

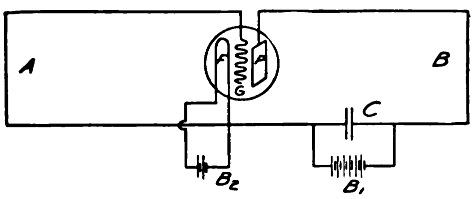

Fig. 6

indeed between the grid and filament. Hence deForest's explanation and that of Armstrong on the action of this circuit do not differ so much after all.

That regeneration can occur under much simpler conditions than that given in the ultraudion has been proved lately by B. Van der Pol, jr.[6] Indeed his circuits $P\,B\,C$ and $G\,A\,C$ (Fig. 6) may be thought of as Lecher and receiver circuits respectively of a Lecher system. Evidently many writers and experimenters[7] are conscious of the existence of a capacity coupling between the grid and the plate of a triode valve though no one seems to have attempted before to explain the nature of this coupling. Van der Pol even remarks that varying the distance between the plates of the external condenser not only varies the capacity in the plate circuit but also the coupling coefficient. In the light of this paper this is readily understood.

It might at first sight appear from equation (**9**) that the effective elastance of a condenser is a function of the electrical constants of the discharge wires with which it happens to be associated. The terms containing the inductances of the primary and secondary circuits have been introduced into the equation to allow for the distributed capacity of the discharge wires. The writer has proved by experiment that the effective elastance of an air condenser is independent of frequency. For circular plates 5 cm. in diameter and 1 mm. thick the mutual elastance E_{12} was determined experimentally by observing the two fundamental wave-lengths λ_1 and λ_2 that existed in the Lecher system when the coupling became tight enough to produce two. Thus k was equal[8] to $\frac{\lambda_2^2 + \lambda_1^2}{\lambda_2^2 - \lambda_1^2}$ and this was set equal to $\frac{E_{12}}{\sqrt{E_{11}\,E_{22}}}$ and E_{12} thereby determined. It is possible to determine E_{12} theoretically from (**11**) or (**14**) in certain simple cases as has been done above for the spherical condenser. In all such cases, however, the capacity of the discharge wires has been ignored and any theoretical value of k or E_{12} could not be expected to agree with the value obtained by experiment. For instance for the plates mentioned above when separated 6.84 mm., k was found to be 0.2243 and since $E_{11} = E_{22} = 0.6109$ e. s. u. E_{12} was found to be 0.1371 e. s. u., and thus E_e was 0.3090 e. s. u. But if the E_e is independent of frequency it is plain that what happens when one attempts by experiment to determine k is that the λ_1 and λ_2 necessarily so change as to hold E_e independent of n and thus the measured value of k and hence E_{12} are lower than the theoretical value just in proportion to the effect of the distributed capacity of the Lecher wires. Thus while E_e is not a function of the inductance of the Lecher wires it is because λ_1 and λ_2 are such as *necessarily* to compensate for what would otherwise appear to be the influence on E_e in equation (**9**) of L_{11} and L_{22}, n being connected with the inductances through equation (**3**). Thus what *does* change with the electrical constants of the discharge wires is the coupling coefficient, being much reduced from the theoretical value because of their distributed capacity. Should one attempt to determine experimentally, for instance, the coupling coefficient between the grid and plate of a thermionic tube he would find it a function of the electrical constants of the plate and grid circuits. Should one represent

$$\frac{E_{12}^2}{(E_{11} - n^2 L_{11})\,(E_{22} - n^2 L_{22})}$$

by k^2, equation (**9**) could be written

$$E_e = (E_{11} - n^2 L_{11})\,(1 - k_1^2), \qquad (25)$$

Whence

$$k_1^2 = \frac{k^2 E_{11} - n^2 L_{11}}{E_{11} - n^2 L_{11}} \qquad (26)$$

For the plates mentioned above, k_1^2 would equal $1 - \frac{E_e}{E_{11} - n^2 L_{11}} = 0.144$ whence $k_1 = 0.338$, and if one substitutes the value of E_e and E_{11} in (**14**) k would

equal 0.702 instead of 0.224 and E_{12} would equal 0.429 instead of 0.137.

Future experimentation alone can determine under what conditions it is important to know the coupling coefficients of a thermionic tube. Equation (**26**) shows, however, that k_1 equals k when both are equal to unity, or in other words when the distributed capacity of the discharge wires can be neglected compared to the condenser capacity. In radio practise one generally employs condensers of large capacity and hence by masking the internal coupling coefficient of a thermionic tube by an outside coupling of unity one reduces the need for knowing the internal coefficient. And yet in Van der Pol's experiments he found oscillation set in when the plates of his external condenser (10-cm. diameter) were 1 cm. apart. Since the ratio of the distance between the plates to their diameter did not differ much from the experiments of the writer, and the capacity and inductance of the external circuits were of about the same magnitude as those of Lecher circuits used by the writer, it is likely that the coefficient of coupling at the moment of oscillation in his experiments was not far from 0.25. Certain types of thermionic tubes, *e. g.*, deForest's "laboratory oscillion," have the ratio of the distance between the grid and plate to the mean diameter of plate not far different from 0.1 and hence their coupling coefficient must in general be distinctly less than unity. Other types are still more open. Van der Pol's experiments seem to call in question the statement made by Miller[9] that the input resistance of a thermionic tube is always positive for a capacity load, for Van der Pol with such a load actually had the tube working as an oscillation generator.

It might be well to point out certain properties of self and mutual elastances and capacitances of conductors as compared with Maxwell's coefficients of potential and capacity. If q_1 and q_2 are charges and v_1 and v_2 potentials then we have Maxwell's well-known equations

$$\left.\begin{aligned} q_1 &= k_{11} v_1 + k_{12} v_2 \\ q_2 &= k_{12} v_1 + k_{22} v_2 \end{aligned}\right\} \tag{27}$$

where k_{11}, k_{22} and k_{12} are capacity coefficients and

$$\left.\begin{aligned} v_1 &= c_{11} q_1 + c_{12} q_2 \\ v_2 &= c_{12} q_1 + c_{22} q_2 \end{aligned}\right\} \tag{28}$$

where c_{11}, c_{22} and c_{12} are coefficients of potential. Maxwell long ago pointed out that all the c's are positive while k_{11} and k_{22} are positive but k_{12} is negative. Now when the second conductor is absent c_{11} is the self elastance, but in general c_{11} as well as c_{12} and c_{22} in (**28**) changes as the two conductors approach each other. So also in (**27**) all the k's are functions of the distance between the conductors and so k_{11} is the self capacitance of the first conductor only when the second conductor is absent. Accordingly there is no justification for calling k_{11} and k_{22} coefficients of (self) capacitance and k_{12} a coefficient of mutual capacitance as is sometimes done. Of course the geometrical configuration of the system of two conductors must enable one to work out the exact relationship between Maxwell's coefficients and the elastances or capacitances for any particular case, *e. g.*, for the spherical condenser given above. For this condenser it is known that $k_{11} = \dfrac{a\,b}{b - a} = -\,k_{12}$ and $k_{22} = \dfrac{b^2}{b - a}$. And it has been shown that $C_{11} = a$ and $C_{12} = b = C_{22}$.

$$\left.\begin{aligned} &\text{Hence} \quad k_{11} = \frac{C_{11}\,C_{22}}{C_{22} - C_{11}}, \; k_{12} = \frac{-\,C_{12}\,C_{11}}{C_{22} - C_{11}} \\ &\text{and} \quad k_{22} = \frac{C_{22}^2}{C_{22} - C_{11}} \\ &\text{or} \quad k_{11} = \frac{1}{E_{11} - E_{22}}, \; k_{12} = \frac{-\dfrac{E_{22}}{E_{12}}}{E_{11} - E_{22}} \\ &\text{and} \quad k_{22} = \frac{\dfrac{E_{11}}{E_{22}}}{E_{11} - E_{22}} \end{aligned}\right\} \tag{29}$$

Those interested have here enough to keep them busy for some time. There is, however, one relationship for infinite distance between conductors that deserves comment. Eliminating the q's and v's between (**27**) and (**28**) one obtains

$$\frac{1 - k_{11}\,c_{11} - k_{12}\,c_{12}}{k_{12}\,c_{11} + k_{22}\,c_{12}} = \frac{k_{11}\,c_{12} + k_{12}\,c_{22}}{1 - k_{12}\,c_{12} - k_{22}\,c_{22}}. \tag{30}$$

If we now put

$k_{11} = k_{22}$ and $c_{11} = c_{22}$ (**30**) reduces to

$$k_{12} = \frac{1}{c_{11} + c_{12}} - k_{11}. \tag{31}$$

With conductors infinitely removed from each other

$$c_{11} = \frac{1}{k_{11}} = E_{11} = \frac{1}{C_{11}} \text{ and } c_{12} = 0 = E_{12}$$

$$= \frac{1}{C_{12}} \text{ hence } k_{12} = 0 \text{ also.}$$

Thus the mutual capacitance is infinity in this case, whereas Maxwell's coefficient of induction (sometimes called the mutual capacitance) is (negative) zero.

In many ways it seems more fundamental to express k^2 as $\dfrac{E_{12}^2}{E_{11}\,E_{22}}$ rather than as $\dfrac{C_{11}\,C_{22}}{C_{12}^2}$ and to this extent the idea of elastance is more fundamental than the idea of capacitance. Hazeltine[10] has pointed out, however, one important difference between electrostatic (elastic) coupling and magnetic coupling.

9. Bureau of Standards, Sci. Paper 351, 1919.

Magnetic couplings may be normal or reversed; not so elastic couplings. If desirous one would be permitted of course to conceive reacting circuits having both elastic and inductive couplings and hence to extend the usual equations of alternating-current theory. The extension will probably only prove useful when the coefficient of coupling is other than unity, that is, whenever in the future open condensers are practicable for one reason or another, the triode valve being already a case in point.

Telephone and radio engineers ordinarily say that a condenser offers a path of "low impedance" to the passage of alternating current. This is of course, correct according to the equation

$$I = \frac{E}{\sqrt{R^2 + \left(\frac{1}{p\,C}\right)^2}}$$

. When the frequency is so high that the reactance outweighs the resistance, then as the frequency increases the impedance decreases and the current through the condenser accordingly increases. Thinking in the terminology of elastance, it is plain from equation (**9**) that the effective elastance of a condenser decreases with increasing frequency, and hence the current through the condenser increases. Either statement is correct but there are some advantages in favor of the latter statement; for a condenser is thought of by students, because of the method of approach in alternating-current theory, as a storehouse of potential energy and they know that the greater the capacity of the condenser the more electricity it will hold. Heaviside long ago[11] pointed out that Maxwell's main notion of a dielectric was its ability to yield to elastic displacement. It will probably be of advantage in training future students of alternating-current electricity to stress more than in the past the presentation of the ideas concerning elastance contained in this paper. Professor Karapetoff[12] has shown the usefulness of the idea of elastance when condensers are joined in series and has called attention to the hydraulic analog of the electrostatic circuit. He has called the reciprocal of the farad the "daraf." Professor Kennelly[13] has also found the idea of elastance useful. But neither of these writers mentions the idea of mutual elastance.

Cordial acknowledgment is made of helpful suggestions received in the preparation of this paper from Dr. A. W. Smith of this laboratory and from Dr. J. H. Dellinger of the Bureau of Standards.

NEW BRIDGE ACROSS THE HAWANG-HO ON THE PEKING-HANKOW RAILWAY

The Bureau of Foreign and Domestic Commerce has received a cabelgram from Commercial Attache Julean Arnold, dated at Peking, China, November 27, 1920 which reports that the Ministry of Communications is calling for bids for a new bridge over the Yellow River (Hwang-Ho) on the Peking-Hankow Railway, to replace the present bridge which has been much criticized as not being of sufficient strength to carry properly the motive power that is being used. The present bridge, which is by far the longest one on this line, is 9,875 feet in length, about 11 feet above high water, partly through trusses and partly deck girder construction, all supported on very elaborately placed screw piling. One-half of the superstructure was fabricated in Belgium and the other half in France, and the floor system is all of the stringer type with the openings filled in with metal plates. It was stated that the permissible loading is very little, if any, in excess of "Cooper E-35", and the appearance of the structures would seem to warrant this statement.

It is understood that the specifications for the new bridge will call for a permissible loading of "Cooper E-50." The length of the new bridge will approximate 10,000 feet and will probably cost between $15,000,000 and $20,000,000. The Ministry of Communications reports that the specifications will be ready sometime this week.

The Bureau has cabled for a set of the specifications which, when received, will be available for consultation at its office, Washington, D. C.

ELECTRIC RESISTANCE OF THE HUMAN BODY

During the past few months some measurements have been made by the Bureau of Standards of the electric resistance of the human body. In this work the measurements were made for the first time in such a way as not to include the resistance through the skin where current entered and left the body. By eliminating the large and uncertain resistances through the skin, results were gotten which are more consistent than any previously obtained. These show that the resistance of the same part of the body of different individuals may differ by a ratio of 3 to 2 or even more, the resistance of a person changes from day to day and often by small amounts in an hour, also the resistance depends to some extent upon the position of the body and the extent to which the muscles are relaxed.

There is reason to think that a part of the difference found between different persons and some of the changes observed in the same persons depend upon pathologic conditions. Such measurements may, therefore, be of interest to the pathologist.

A knowledge of the resistance of different parts of the body exclusive of the skin may also be of interest to those concerned with life hazards from high-voltage circuits, since when accidental contact is made to such circuits the skin is burned at the point of contact and therefore largely loses its protecting property.

Operating Performance of Insulators on a 45,000-Volt System

BY H. B. VINCENT

Management Engineer, Day & Zimmermann, Inc.

A description of a form used for collecting data pertaining to the condition of pin-type high-tension insulators removed from service. An analysis of the data obtained from such a report showing the performance of insulators on various lines from 1914 to 1919 inclusive. Percentage of injured and damaged insulators to total installed, and percentage of nature of damage to total failures.

Introduction

As a considerable amount of data has been published in connection with the manufacture, mechanical strength, electrical stresses and laboratory tests of high-tension insulators, it is my purpose to confine mine only to their operating performance.

The following data which refer entirely to pin type insulators have been gathered from actual records kept by a power company operating in the central part of Pennsylvania.

General Description of System

The company transmits and distributes power for mines, industries, street railways, municipal lighting, commercial power and lighting and residences over an area of approximately 350 square miles, serving about 20,000 customers.

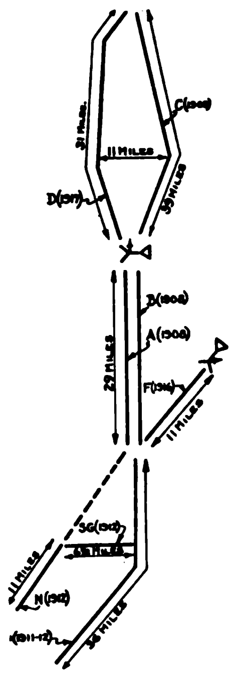

Fig. 1—Diagram of 45,000-Volt System

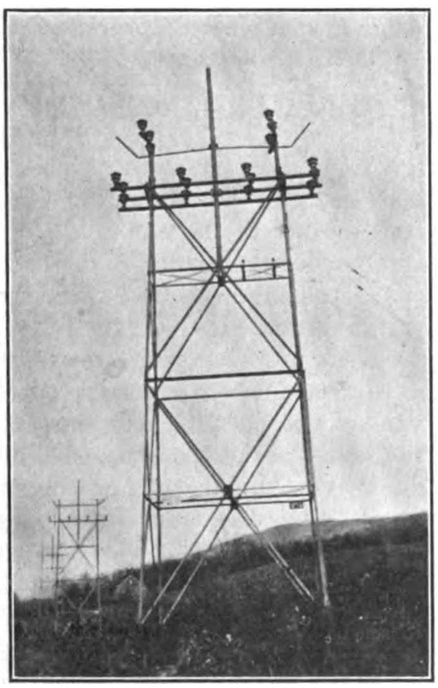

Fig. 2

The power which was originally generated at several separate plants is at present being generated at two plants having a total capacity of 23,500 kv-a. The generating voltage (2200 and 6600 volts) is stepped up to 45,000 volts, which is the major transmission line voltage, the transformers being connected in star with neutral grounded on the high- and delta on the low-tension side.

Fig. 1 shows diagrammatically the 45,000-volt system, the letters designating the various lines being those referred to in the curves shown later.

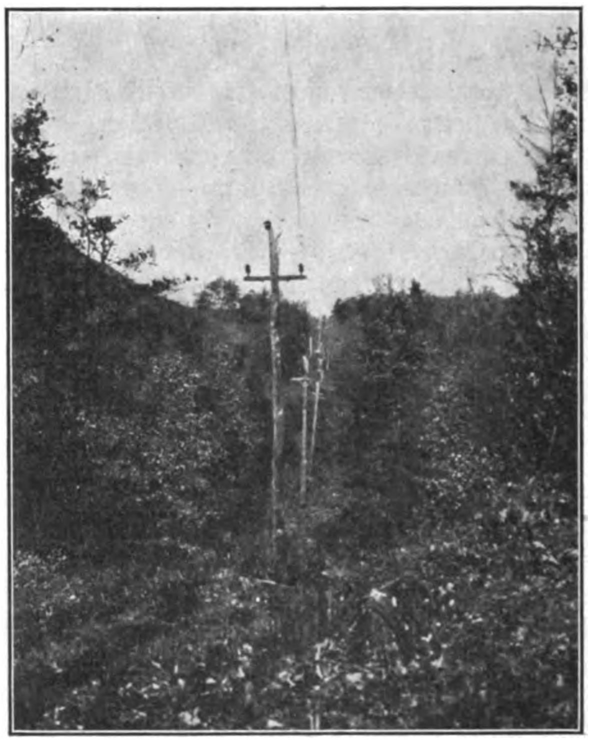

Fig. 3

Types of Construction

The type of construction of the various lines under discussion in general is as follows:

A and *B* is a double-circuit steel tower line, erected in 1908 (Fig. 2).

C is a single-circuit wood pole line with wood cross-arm and steel ridge pin, the latter being grounded through a common bolt with overhead ground support, erected in 1909 (Fig. 3).

D is a single-circuit wood pole line with steel *B-A* arms grounded through the bayonet, erected in 1917 (Fig. 4).

F is a single-circuit steel pole line, erected in 1916 (Fig. 5).

N is a double-circuit steel *A* frame line (with but one circuit installed), erected in 1912 (Fig. 6); the portion shown dotted is similar to *S* line and is

Presented at A. I. E. E. Section Meetings, Ithaca, N. Y., February 27, 1920; Philadelphia, Pa., March 8, 1920.

not included in the following analysis as it was only put into operation recently.

S is a single-circuit wood pole line with wood cross-arms and steel ridge pins ungrounded, erected in 1911-12 (Fig. 7).

S G same as *S* line.

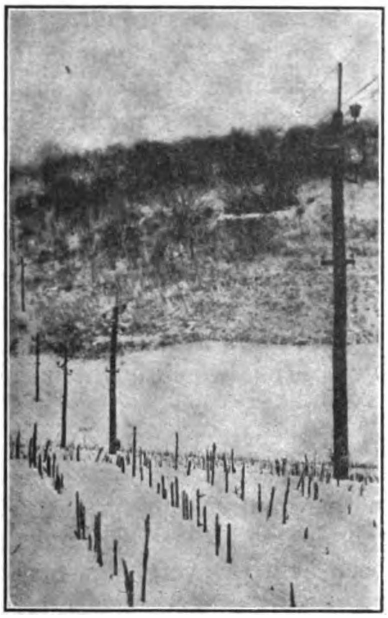

FIG. 4

All the lines are equipped with a quarter-inch Siemans Martin double galvanized stranded overhead ground wire (except *A-B* line which has half-inch), grounded approximately every 800 ft. to a two-inch galvanized iron pipe 6.5 ft. in the ground.

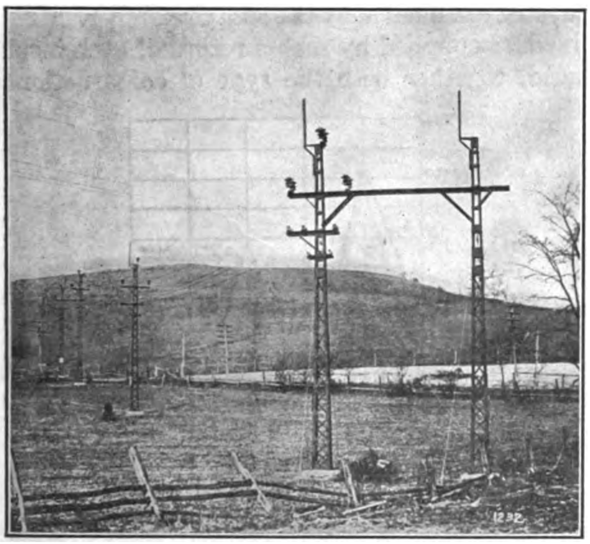

FIG. 5

The normal spans on the steel tower line are 400 feet, on the steel *A* frame, and steel poles 300 feet, and on the wood poles 200 feet (except in particularly severe sleet districts 150 feet).

All pins are metal and in the case of *A-B* lines are cemented directly into the insulators; on *D* line the pins have a separable lead-covered steel thimble which eliminates cementing; on the balance of the lines the

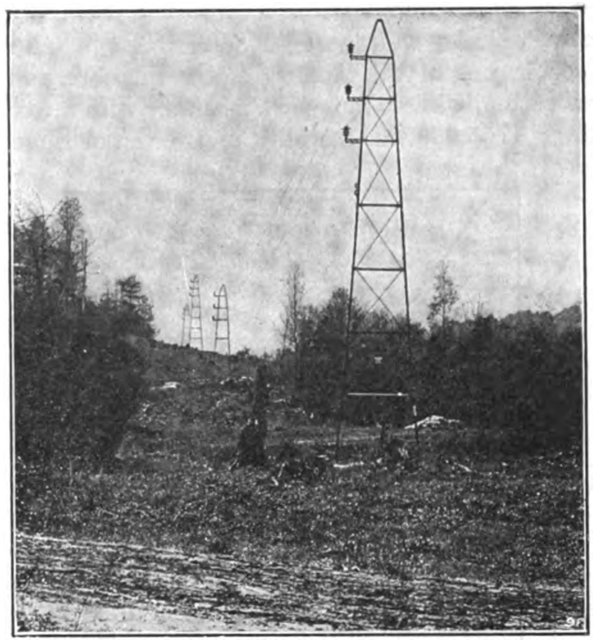

FIG. 6

pins screw into a metal thimble cemented into the insulator.

Both aluminum and copper stranded cables are used for the conductors.

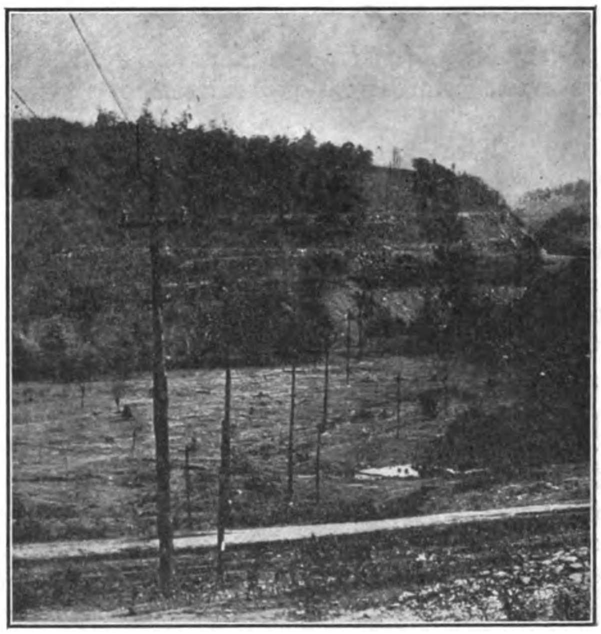

FIG. 7

NATURE OF TOPOGRAPHY

The majority of the lines traverse very mountainous country and are subject to severe lightning, sleet and wind storms, although there are sections which follow valleys or lowlands for some considerable distance.

The maximum elevation is about 2400 feet and minimum about 550 feet.

TYPE OF INSULATORS

The insulators installed on the first three circuits erected (*A*, *B* and *C*), were three-part with a rated line or working voltage of 50,000; those installed on the crossarms of the balance of the lines were of the same rating, while a four-part insulator with a working voltage of 60,000 was installed on the top or ridge pin.

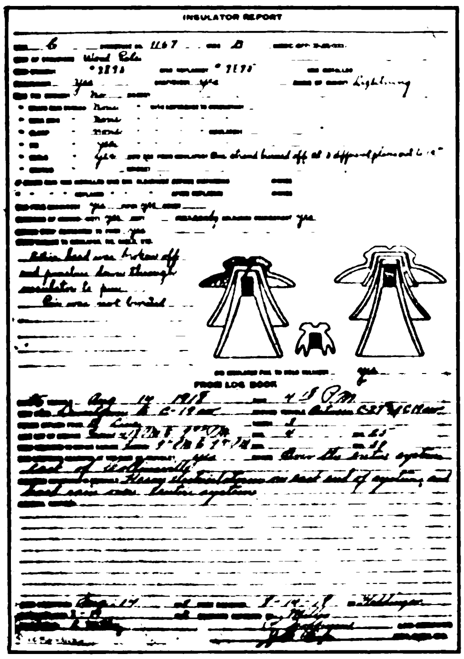

FIG. 8

With very few exceptions all strains and dead ends are made on two or three pin-type insulators.

TIES, SERVING AND SHIELDS

Both tie clamps and regular ties have been used, though the present practise is to use only the latter. Special serving and shields have only been used on crossings of other facilities, and then only when the latter's specifications required them.

No metal caps have been used except on line or disconnecting switches.

RELAY PROTECTION

The original lines were installed with overload inverse-time element relays, but as the size of the system grew, through the addition of lines, difficulty was experienced in obtaining proper selective action in case of short circuits; this was overcome by replacing the inverse-time element relays by definite and inverse-definite time limit relays.

PATROL TESTING

No special means are employed for detecting faulty insulators in service; a regular weekly patrol is maintained, augmented by special patrols following severe storms or where momentary interruptions would indicate some unknown trouble.

SPECIAL TESTING

The company has installed a high-frequency testing outfit which is used for comparative tests.

LIGHTNING STORMS

Inasmuch as lightning plays such an important role in high-tension operation a record has been kept of the number of storms occurring at different points on the system, which allows of at least a relative comparison between yearly damage and quantity of each season's storms.

Since such a record has been kept of the lightning storms an effort has been made to determine if they were more severe or frequent in any particular location of the system with consequent greater insulator damage, but nothing definite has been brought out by the analysis.

RECORDS

No detail records were kept of the performance of insulators on the transmission system prior to 1914. However, beginning with that year, and since, a detail record has been kept of every high-tension insulator removed from the lines together with a record of the style and make of the one replaced by it. The form of record used (Fig. 8) is probably similar to that used by other operating companies. That portion of the form dealing with physical conditions, *i. e.*, the structure, number, style and location of insulator, evidence of burns and actual conditions of insulator as found, is filled in by the repairman or lineman who changed the insulator. The operating data, *i. e.*, when the line failed, etc., are filled in by the load dispatcher.

The data supplied by such a record of each insulator replaced, together with the type of construction and

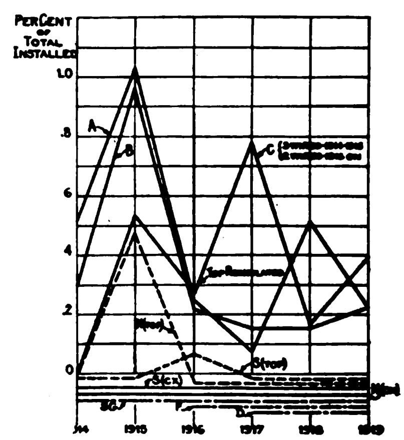

FIG. 9—YEARLY PER CENT OF INSULATORS INJURED BY CRACKS—BY LINES

date when the line was put into operation, permit an analysis to be made at any time of its performance with respect to style and age, and should show if a particular weakness is developing.

Classification of Insulator Defects

For the purpose of the following analysis the insulator defects have been subdivided as follows:

a. Cracks, *i. e.*, those which have been removed from the line due to mechanical defects, which defects were found by special inspection or by excessive static conditions being noted by the patrolman.

b. Injured, *i. e.*, those which held voltage but which were considered a menace to operation, although such an injury might have been caused by a rifle shot or stone; only those showing signs of a flash-over have been considered.

c. Damaged, *i. e.*, those which failed to hold voltage, such damage being a flash-over, a vertical or a horizontal puncture.

Analysis of Insulator Reports

a. Cracked Insulators. In Fig. 9 is shown the yearly percentage of insulators injured by cracks by lines, from which it will be seen that excepting the very small per cent on the top wire of S line, the defects

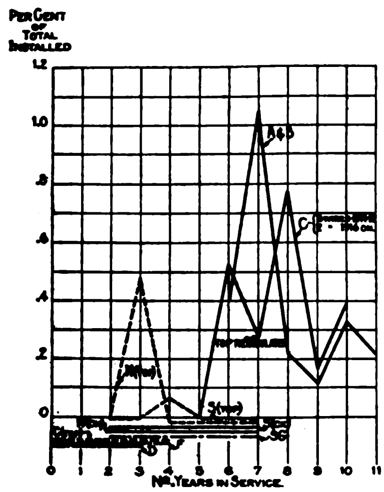

Fig. 10—Per Cent Insulators Injured by Cracks with Respect to Years of Service—By Lines

have been occurring on A, B and C lines. This condition was discovered primarily by an investigation of the increase of insulators damaged in 1915 over 1914, a mechanical inspection being made after the 1915 lightning season.

As the majority of failures on C line were occurring on the ridge pin (which, as previously stated, was grounded) it was decided to reinsulate this top wire. This was done before the 1916 lightning season, which is reflected in the decrease in damaged insulators on that line as seen by a later chart. In reinsulating the top wire a four-part insulator with a working voltage of 60,000 was used.

It will be noted that there was a larger percentage on A and B lines; these lines were not reinsulated at that time due to the fact that they formed a duplicate circuit, but due to the increasing number of failures in the past two years A line will be entirely reinsulated before the coming lightning season.

In the case of the latter lines all three wires showed about the same per cent of injured insulators.

The question is often asked, "What is the life of an insulator?" This can hardly be answered, but from the records of the particular system in question we have decided that in the case of A, B and C lines the service being obtained by these insulators warrants their removal.

In Fig. 10 we have shown the percentage of insulators injured by cracks with respect to years of service by lines, from which it will be noted that, in the case of A, B and C lines, trouble started after five or six years. Although some of the other lines show no signs of cracking, these insulators are of a later design.

The cracking referred to in almost all cases has occurred in the top skirt, causing the head to shear off in the plane of the tie wire groove, due we believe to unequal expansion and contraction between the porcelain and cement, caused by aging of the latter material.

Although we have not experienced any trouble with the insulators on the 45,000-volt system, which might be attributed to cementing the pin to the insulator, we have had this trouble with insulators used on a lower voltage line, hence our present practise is to use a lead thread or thimble in place of cement and metal thimble.

b. Injured Insulators. The performance of the insulators on the various lines with respect to injury due to flash-over is shown in Table I.

TABLE I

Percentage of (total) Insulators Injured by Flash-over—By Lines

Lines	1914	1915	1916	1917	1918	1919
A & B	0.15	0.33	0.29	0.18	0.91	0.69
C	0	0.08	0.03	0	0.10	0.03
D				0	0	0.09
F			0	0.32	0.11	0.11
N	0.16	0.47	0	0	0.16	0
S	0	0	0.05	0.09	0.16	0.02
SG	0	0.13	0	0	0.13	0

As far as the records show these flash-overs were caused by lightning.

A detailed analysis shows double the percentage of flash-over of the top wire insulator over the cross-arm or bottom insulators on S and F lines since 1914. However, if all of the lines are considered the percentage is about equal.

The records further show that the percentage since 1914 on the grounded pins is 0.95 against 0.29 on the ungrounded pins.

c. Damaged Insulators. Fig. 11 shows the yearly percentage of insulators damaged by lines. A decrease in failures is noted on C line as a result of the reinsulation of the top wire in 1916, but failures have increased since 1917. Although the same type of

insulator as used on the top wires of *F*, *N* and *S* lines (which shows practically no failures) was used to reinsulate the top of *C* line, it will be noted that an increasing number of failures are occurring on the reinsulated line, the cause for which has not yet been determined.

The relatively large number of failures on *A* and *B* lines is no doubt being caused by the cracking of the top skirt previously referred to.

The failures occurring on the various lines with respect to years of service are shown in Fig. 12.

Fig. 13 shows the yearly percentage of insulators damaged, by styles, and also the number of days lightning occurred.

A detailed analysis showing the failures segregated between the top wire and crossarm in percentage of total number of each installed by styles is shown in Table II.

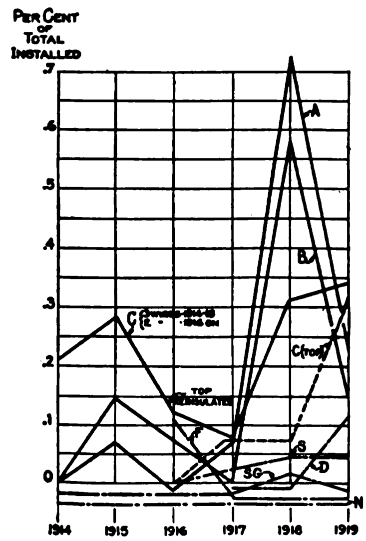

FIG 11—YEARLY PER CENT OF INSULATORS DAMAGED—BY LINES

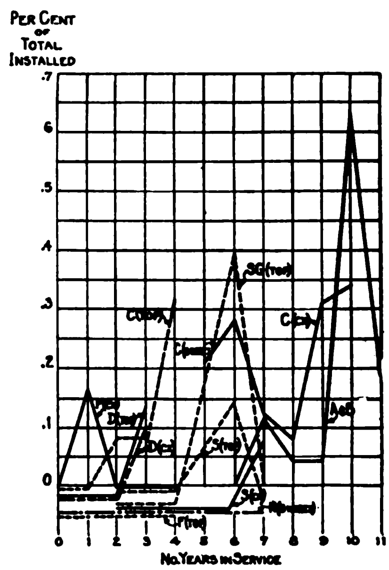

FIG. 12—PER CENT OF INSULATORS DAMAGED WITH RESPECT TO YEARS OF SERVICE—BY LINES

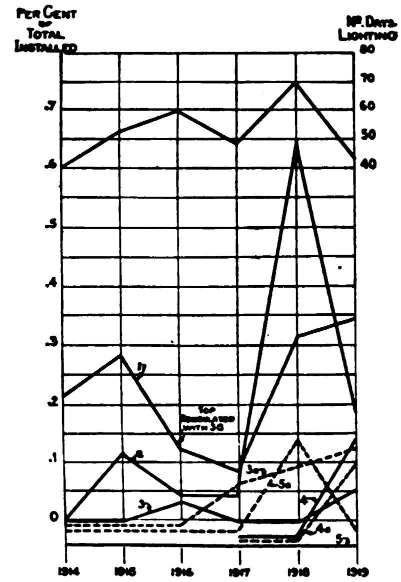

FIG. 13—PER CENT OF INSULATORS DAMAGED BY STYLES, AND NUMBER DAYS LIGHTNING OCCURRED

TABLE II
Percentage of (total) Insulators Damaged—By Styles

No. Parts	Styles	1914	1915	1916	1918	1919	1919
Crossarm Wires							
3	1	0.08	0.08	0.12	0.08	0.31	0.34
3	2	0	0.03	0.02	0	0.60	0.80
3	3	0	0	0.03	0	0	0.05
3	4				0	0	0.13
3	5	0	0	0	0	0	0
Top Wires							
3	1	0.47	0.70				
3	2	0	0.11	0	0.11	0.77	0.22
4	3a	0	0	0	0.06	0.09	0.12
4	4a				0	0	0.09
	5a	0	0	0	0	0.13	0
Total Crossarm		0.02	0.05	0.06	0.02	0.17	0.15
Total Top		0.15	0.24	0	0.05	0.20	0.13

A further segregation of the damaged insulators into nature of damage shows the following for the total period of time (1914 to 1919 inclusive) the records have been kept:

Vertical puncture.........27.4 per cent
Horizontal puncture.......39.0 per cent
Flash-over...............33.6 per cent

CONCLUSIONS

The effect of the performance of the insulators on interruptions or continuity of service has not been touched upon, but since the records have been kept analyses have been made in particular cases.

To make such an analysis each of the individual lines would have to be treated separately and jointly, depending on operating conditions at the time of the trouble; further, the duration of the interruptions varies, depending on the location of the faulty insulators and the accessibility of that section of the line.

In the case of the disk-type insulators, quite a few operating companies are keeping complete records of their performance, and from the nature of the insulator are able to make periodic tests of each unit, and by providing a high factor of insulation can replace weak or defective units to reduce the probability of complete failure.

From a study of the high-voltage pin-type insulators now on the market it would seem that the manufacturers are endeavoring to overcome the cracking of the parts, but the operating companies will have to do their part by supplying reliable data in connection with the actual performance under operating conditions.

Hence my thought has been simply to present a method for the recording of insulator performance, showing how such a record enables one to know what service the insulators are giving, and what one may expect provided the records have been kept over a sufficient period of time.

The Application of Electric Power to the Rubber Industry

BY THE SUB-COMMITTEE OF THE INDUSTRIAL AND DOMESTIC POWER COMMITTEE ON THE RUBBER INDUSTRY*

INTRODUCTION

HISTORY shows that something was known of rubber to civilization as early as 1525. In 1736 a French expedition of scientists, who were sent to South America for geographical research, sent back samples of rubber, and reported that it was obtained from a certain tree which the natives called *hevea*. Even at this early date they further reported that the natives were using this material to waterproof various articles of wearing apparel. This material was soon used in England for removing pencil marks, and hence has been termed *rubber*.

About the beginning of the nineteenth century Samuel Peal and Charles Macintosh, both of England, in turn, proposed the use of rubber in solution for impregnating fabric. The former attempted to make air-cushioned beds, and the latter made waterproofed rain coats. The attempt of Macintosh in 1820 marks the first important step toward the application of rubber to the needs of civilization.

It was not however until Charles Goodyear in 1839 made his almost accidental discovery of vulcanization, that rubber promised to become a material of a very important and far-reaching industry. The facts that the addition of sulphur to crude rubber, and as later learned, adding sulphur with other compounding ingredients to rubber, and subjecting the mixture to heat, so that the mass became *cured*, making further changes of its physical properties practically unchangeable within reasonable ranges of temperature; and further that the compounding materials could be adapted, both in kind, and in amount, to produce a rubber of widely varying physical characteristics; all laid the foundation for an industry which today is manufacturing articles of universal use and application, and, according to Government statistics, stands at the head of the list of "Individual Large Users of Electric Power."

Crude Rubber is obtained from certain species of tropical and sub-tropical trees, shrubs, vines, and the roots of certain plants. In the case of trees and some vines it is coagulated from the milk-like fluid known as latex which exudes from cuts or sores in the bark, while rubber exists in some vines and most shrubs in a solid form incorporated with the woody fiber. In the case of the latter the rubber is obtained by complete maceration of the entire shrub by the means of suitable pulp grinding machinery assisted by the use of water, which carries off the pulp and bark while the rubber is reduced to an agglomerate mass, and passes out of a suitable opening provided in the machine.

The various grades and brands of rubber are usually known by the name of the geographical locations in which they are obtained. This nomenclature is especially common among practical rubber men. It is now true that there is a tendency, especially among engineers and chemists, to speak of rubber according to a botanical or other scientific classification. The finest quality of rubber is obtained from South America, while grades of less value are obtained from Central America, and Mexico, and some of the shrub variety from Texas. Large quantities of rubber with some very good grades are secured from the tropical, and sub-tropical regions of Africa, Asia and Australia.

Milling and Washing of a thorough character of all grades of rubber are essential. At the plantations it is either run through a sheeting mill, or through a creping mill, while in the case of those kinds shipped without receiving either of the above operations, it is thoroughly mechanically disintegrated in a washing mill at the various rubber factories.

Summary of Committee Activity

United States Government statistics show the rubber industry to be the largest individual user of electric power.

How this large amount of electric power is applied, is the duty of this committee to show. We hope that our work may assist the engineer in electric power application problems, to render this large power more efficient, and thus help assist humanity in its efforts toward conservation.

This committee has planned its work to include a number of divisions, each division being sub-divided, making it more easy to digest.

POWER CONSUMPTION

1. *Basic Machinery Applications*. The power demands in this division are for electrical units of relatively large horse power and constant speed. These general milling operations embrace the following machines:

To be presented at the Akron-Cleveland, Ohio, Meeting of the A. I. E. E. January 14, 1921.

*WILLIAM E. DATE, Chairman, Cutler-Hammer Mfg. Co., New York, N. Y.

MARTIN BERTHOLD, Imperial Electric Co., Akron, O.

BYRON T. MOTTINGER, Quaker City Rubber Co., Philadelphia

CHARLES A. RICE, Republic Rubber Co., Youngstown, O.

HENRY F. SCHIPPEL, Aimes, Holden, McCready, Ltd., Montreal, Canada.

a. Washers.
b. Crackers.
c. Mixers.
d. Batch mixers.
e. Safety stops.

2. *Intermediate Process Applications.* The power demand in this division is met as a rule by special applications of moderate-size electrical units, adjustable speed.

Semi-Finishing Machines
Calenders and Calender Drives.
a. Individual drives.
b. Conveyers.
c. Synchronous control of calenders, and of calenders and conveyers.

3. *Finishing Process Applications.* The power demand in this division is for electrical units of relatively small capacity. Constant speed as a rule. Some machines require adjustable speed, continuous running. Others are intermittent, frequent "start" and "stop," and some types must be equipped for frequent "reversals."

Finishing Machinery.
a. Fabric bias cutter.
b. Tire building machinery.
c. Tubing machines.
d. Insulating machines.
e. Hose loom.
f. Hose braiding machines.
g. Hose wrapping machines.
h. Hose stripping machines.
i. Hose building machines.
j. Rubber shoe machinery.
k. Rubber glove machinery.
l. Hard rubber machinery.
m. Mechanical rubber goods machinery.

4. *Electric Heating Applications.* Only a limited amount of electric heating has been applied to the rubber industry. Possible applications are being investigated.

5. *Contributory Problems and Applications.*
Power Supply. Transmission.
a. Power and lighting switchboards.
b. Transformation of alternating current to direct current for adjustable motor speed requirements.
c. Air compressors.
d. Hydraulic pumps.
e. Elevators and hoists.
f. Floor and street trucks.

Power Economy

A study of the subject in the abstract, should show the engineer where, by making a power application of a certain type in one division, he may lessen the losses in another division.

A study should be made of each concrete problem, selecting units of relatively low initial torque but high all day efficiency where high initial torque is not required; and selecting units of relatively high initial torque, and of a continuous load capacity suitable for the work, so that power efficiency can be increased. This conclusion is reached without overlooking the facts, that much of the rubber mill machinery is subject to high peak loads, and that continuity of operation is of importance to production.

It is not the intent of this paper to reflect in any manner against the progress that has been made, but to suggest that possibly greater care should be taken in selecting electrical equipment of the most suitable type and size for each application so that increased efficiency will obtain.

Protection to Operatives

Owing to the tenacious characteristic of rubber in its plastic state, a hazard to the mill operators is at all times present. Hence the need of safety protection is imperative.

Conclusions

a. Possibilities of electric power.
b. Application of 40-degree and 50-degree motors.
c. Steam *vs.* electrically heated drying ovens, (250 deg. fahr.)
d. Steam *vs.* electric heat treatment of vegetable compounds. (250 deg. fahr.).

BASIC OPERATIONS

General Considerations

Processes

The general milling or basic operations obtain in every class of manufacture of rubber articles.

It is in this general division that the crude rubber is treated, compounded and probably colored, to produce the mixture required for the specific need. The per cent of pure rubber in different articles is a large variable, being high in one class, and low in another. In general milling operations, there are many variables that affect the power requirement. Examples: Source of supply of crude rubber. Working temperature of rolls. Pressure on rolls. Grade of compound or mixture.

General milling operations include the "washing," "cracking," "mixing," and finally "batch warming" ready for the calenders.

Motor Selection

Gearless Drive. The earlier type of motor drive involved a moderate-speed motor, geared to the mill shaft through spur gear reduction gears, the gear ratio employed, as a rule, being approximately 1 to 6, to provide a mill-line shaft speed of approximately 90 rev. per min. Of recent years, the herringbone gear became popular for rubber mill machinery, with the result that a large proportion of installations made during the past few years have been equipped with herringbone gears.

The prevalent tendency is an endeavor to eliminate the gear reduction, and connect the motor shaft directly to the mill-line shaft. This requires a very low-speed motor, and is impracticable with large size induction motors, either of the squirrel-cage-rotor, or of the wound-rotor type. The synchronous motor however is readily adaptable to this low speed and provides the advantages of high power factor, which is of large significance in view of the widely varying loads encountered in milling, in addition to the elimination of costly, noisy gearing. The elimination of gear maintenance is a large factor.

The first gearless installations made, of which this committee has record, are at the plant of the Republic Tire and Rubber Company, Youngstown, O. These were installed many years ago, and the reports obtained by this committee indicate that the company feels after years of operation that its judgment was sound in their selection.

The point we wish to bring out, however, is the possibilities of the gearless drive. This question settled it simply becomes a question then, of selecting the suitable modern type of low-speed motor.

Voltage. The majority of milling operations require motors of large capacity and of constant-speed characteristics. That these motors may advantageously be of high voltage, direct from service lines, eliminating step-down transformers with their additional losses, is a factor worthy of consideration in power application.

Motor Size. Several factors are included in the selection of motor size and some of them to our minds improperly. To clearly stress these last, there immediately follows a discussion of *horse power rating* and *power factor and efficiency at full rated load,* following which will be indicated with discussion the two factors *torque* and *thermal capacity* that alone count.

Horse power rating means simply that a motor will, when developing a defined rated torque (known as full-load rated torque), at a defined rate of speed (known as full-load rated speed), have a temperature rise, not in excess of a defined value.

This may be amplified by time limitation, such as 30-minute rating; one-hour rating; two-hour rating; but it assumes a constant load.

In milling operations does this condition exist?

The load, that obtains in milling operations, has a possible variation from a minimum of friction load, with all mills empty, up to a possible maximum of simultaneous loading of all mills on the line.

With an individual drive (one mill only for each motor), both the minimum, and maximum condition will obtain. With two mills the same result is probable. With three mills to a drive, it is probable at infrequent intervals. With increasing number of mills to a drive the probability of obtaining the possible maximum peak load decreases. With five mills the probability is that the maximum load at any one time will be 75 per cent of the possible maximum. With eight mills to a drive the probable maximum load will be 50 per cent of the possible maximum. The greater the number of mills to the line, the more closely is a constant-load condition approached.

This is not intended as a justification of placing all mills in a plant on one mill line. The number of mills, and sizes of mills to a mill line are governed by local conditions over which the electrical engineer has no control.

The purpose is to emphasize the conditions which confront us in motor size selection.

We want to bring out clearly:

1. That greater number of mills to the mill-line drive does not increase maximum torque requirement proportionately.

2. That greater number of mills to the mill-line drive does eliminate to some extent the depth of the valleys in the load curve, and that the peak loads do not increase proportionately to the number of mills.

The two important factors are: Torque, and thermal capacity.

a. Select a motor having a pull-out torque capacity in excess of the maximum torque requirements; this motor to have a thermal capacity sufficient to carry the mean load continuously without heating beyond prescribed temperature rise limit.

b. This motor should have a high mean power factor carrying the mean load determined for the thermal capacity selection.

c. This motor should have a high mean efficiency, carrying the mean load determined for the thermal capacity selection.

d. This motor should have high speed regulation characteristics when carrying the loads that obtain when developing any torque, between 20 per cent of the maximum torque pull-out value, and maximum torque pull-out value.

e. This motor should be mechanically constructed so as to withstand the load shocks imposed by the frequent peak loads that obtain. (Caution should be exercised to obtain ample size of shaft, bearings, and rotor structure).

A motor selected on this basis would not be over-size. Over-size motors increase investment, have a lower combined mean power factor efficiency, and are not justified for economical production.

If motors have poor speed regulation characteristics, under the varying loads that obtain, production is lessened. One example of motor selection on this basis can be cited, and there are probably many others.

In 1915 an installation of 40 mixers was contemplated for low-grade compound for one plant. The plan was to operate in groups of two, with a total of 20 drives. One machinery manufacturer offered 100-h. p. motors. Another 75-h. p. The engineer, considering the nature of the compound, was satisfied with

neither. The order was placed for the mills, and the motor size selection withheld 30 days, during which time a continuous test was made with a graphic meter (24 hours per day, three shifts of workmen), on the same size of mills and the same mixture of compound.

The result, was the selection of motors nominally rated at 50 h. p. but which had ample pull-out torque capacity for the peak loads, and ample thermal capacity rating for the mean load. These motors have now been in successful operation for over three years, and over a considerable period of time were operated 24 hours per day.

In 1919 eight similar drives were added.

In another plant is a four-mill drive fitted with a 400-h. p. nominal rating motor. A test with all mills operating showed a maximum load of 300 h. p. After several hours of test showing a load fluctuating between 50 h. p. and 300 h. p., an appeal was made to the superintendent to provide conditions that would give a maximum load condition.

The superintendent had a special grade of stock trucked in for the test. He instructed all workmen to handle the work in a manner to provide the maximum load possible, and the highest load peak obtained was 405 h. p.

These examples are not offered as a plea for small or under-size motors, but simply to emphasize against the waste of using over-size motors.

Motor Controller. The motor controller recommended by this committee for general milling work would comply with the following specifications:

a. Controller to be of a totally enclosed type.

b. Controller to be manually operated, from a lever or external mechanism.

c. Controller to be fitted with inverse-time-limit overload protection.

d. Controller to be fitted with low-voltage protection.

e. Controller primary switching mechanism to be of a type suitable to the voltage of the system. For 550 volts or less, air-break, fully enclosed, primary switching mechanism to be preferred. For 2200 volts or higher, the switching mechanism of the primary switch to be oil-immersed.

f. The resistor, if required, to be of cast metal grids, 30-second duty rating, open structure, for mounting separate from the controller.

g. The controller to be interlocked with the safety stop mechanism so that the motor cannot be started with any of the safety stop devices in the "safe" position.

Washers

Crude Rubber to Pure Rubber

Crude rubber, whether *wild*, or *plantation*, is a dirty brown mass. It may be in the form of large balls, small balls, or rectangular chunks. In any event it is a conglomeration of dirty gum, sand, stones, and sticks. It may be "smoky," or it may not be.

It must not only be "washed," but it must be disintegrated, and the rubber particles separated from all foreign substance. When thoroughly washed, disintegrated and separated, the color of the resultant granule is that of rich cream. Thus, the change from *crude* rubber to *pure* rubber. The quality of the pure rubber is dependent largely on the geographical source of supply of the crude rubber.

Continuation of the washing produces coagulation, and results in rough uneven crepe-like sheets, of about the size of a page of your daily newspaper.

If the *sheeting* term is disregarded and the mind is placed on a granular substance, such as granulated sugar, the next phase of procedure will be more readily understood. We must now change the "granulated sugar" into "taffy."

The next operation causes coalescence. The granules are broken down, and fused, resulting in heavy sheets of pure gum approximately ⅜ inch in thickness. Although water is not used in this phase of the process, we class it with washing, in that the accounting systems of many plants use the same classification.

The crude rubber is "accounted out" to the washer room as crude rubber, and is "accounted back" to the store room from the breaking-down mills, as the resultant product of these various procedures.

Motor Selection

Disintegration. This process involves machines, known as "washers" in some plants, and as "crackers" in others.

The rolls on these machines are fluted spirally. Both rolls are fluted in the same direction, but are rotated in opposite directions. The speed of one roll is higher than the other. The ratio of friction is unusually high, as a rule. This ratio is as high on many machines as 1 to 1⅜. The distance between the rolls may be ⅜ inch or greater.

Analysis of this type of machine and the material it must handle shows the following load characteristics; all of which obtain simultaneously, and all of which are in the nature of suddenly applied loads:

a. A relatively short heavy chunk of cold crude rubber forced into the V between the rolls, until the rolls grip and wedge it through, causes a heavy suddenly applied load, with resultant shock.

b. The spirally fluted rolls, one of higher peripheral speed than the other, cause a combination of dragging in, wedging, crushing, cutting and tearing apart action producing a heavy, suddenly applied load, with resultant shock.

c. The high ratio of friction, the peripheral speed of one roll so much greater than the other, is a large factor in itself toward producing a heavy, suddenly applied load with the resultant shock.

d. The wide separation between rolls is another large factor toward producing a heavy, suddenly applied load with resultant shock.

All of the foregoing indicate that every characteristic produces heavy suddenly applied loads with resultant shock. Aside from the mechanical ability of the motor to meet high shock demands there must be that ability in the motor to pull through the peak. There must be the required turning ability in the motor to absorb the resultant shocks. Turning capacity is the essential feature for peak loads.

There is one redeeming feature to washer work. The peak loads are of short duration. The peak load obtains only when the heavy, cold chunks are passed through. The actual time of passing a chunk through the washer, assuming good speed regulation, would be from $^2/_3$ of a second, to $1\frac{1}{2}$ seconds. It is possible to have this condition repeated in rapid succession. This could result from feeding chunks to the washer in rapid succession.

Nevertheless, the peaks are of short time duration and kinetic energy of rotation should be included in calculations determining motor size selection.

The turning ability then can be the result of two factors. *Inertia* and *torque*. If the inertia is relatively high, the torque may be proportionately decreased, so that the sum of the two is of ample capacity to carry any reasonable peak load.

It is fallacy to permit mill operators to force the mills to do unreasonable work, and it is not good practise to equip a mill or mill line with motors of a capacity largely in excess of that of the mechanical equipment. The mechanical equipment is designed to absorb all reasonable shocks. The motor capacity should be proportionate and the motor should have suitable protective devices to protect it in event of attempted abuse by operators. When this protective device stops the mill line, there should be no attempt made to force the motor and mill line to do the unreasonable, that which it is not designed to do. The jammed material should be backed out of the mills or the pressure on the rolls released, thereby relieving the equipment of unreasonable abuse.

If this cooperation obtains between the production department and the engineer there will be no temptation to equip with motors largely in excess of reasonable requirements or in excess of the capacity of the mechanical equipment.

A suggestion that is not irrevelant at this stage, would be the installation of a visible signal on each washer mill. This signal would indicate to the operator at any time that the reasonable load point had been attained. The operator on any one mill would know that the mill line was up to capacity. Each would know at once whether his individual mill were overworked; if not, he would feed with reason; if so, he would delay further feeding. Non-attention to the signal and further forcing and abuse would cause a shut-down on the mill line.

With a signal system of this nature the motor size selection may be on a basis of reasonable peak load, with assurance that not only the motor but the entire mechanical equipment as well, will suffer little abuse.

Then,—(1) With a true knowledge of the nature of the material to be washed, (2) With a true analysis of the characteristics of the machine, (3) With a thorough understanding of what is a reasonable peak load, the problem as far as turning capacity is concerned, simply becomes one of selecting that type of motor which is best suited to the plant conditions and to the mechanical structure of the drives, that is, whether geared or gearless.

Due consideration must be given to a washer line where a number of washers are involved. Also to a mill line that may incorporate sheeting and breaking-down rolls.

The law of average will obtain on a mill line driving a number of washers, or a mill line driving a number of mills of different types.

On washer mill lines the engineer may make a formula along the following lines, such to be based on tests in his own plant under the class of material conditions and the working conditions that obtain there. The formula here presented represents average plant conditions, as owing to the many variables it is impossible to offer a formula that is applicable to all.

Assume one washer on a given stock, reaonable peak load to equal 100 per cent.

Let N = number of washers
K = a constant

TABLE OF CONSTANTS

No. of Washers	K equals
1	1.00
2	1.00
3	0.85
4	0.82
5	0.80
6	0.72
7	0.67
8	0.62

The formula then would become 100 per cent $X\ N\ X\ K$ = peak load capacity required for a given number of washers in per cent of the peak load capacity required by one mill.

Assume a given size of washer requires a peak load capacity equal to 132 actual h.p., then four such mills would on this basis indicate a peak load requirement of 432.96 h. p.

The constants given here are average, and are conservative considering the test data available. They should not be considered, however, as recommended working constants. Each problem should be studied from its own or similar plant conditions.

It is important however to bear in mind, that calculations should be based on peak load capacity of the motor, and not on the nominal h. p. rating. This is of especial importance if applied to synchronous motors, as there is a wide difference between the maximum torque capacity of the synchronous motor and the in-

duction motor. It is also important as there is frequently an appreciable difference between the maximum torque capacity of different induction motors of the same nominal h. p. rating.

The important point is the selection of a motor of sufficient turning capacity, when operating at its rated speed, to carry through those peak loads that have been determined as reasonable. Second, to signal the operators when they have attained that peak load, that has been determined as reasonable. Third, to shut the line down, should the peak assume an injurious proportion.

The following abridged list is given of some existing installations which were selected at random, and not purposely to show the wide divergency in motor selection that it is possible to show. They are included to emphasize the fact that a definite basis of selection cannot be given. At least not until all available data, and all data that it may be possible to secure, have been brought together under one head, thoroughly analyzed and tabulated.

SOME TYPICAL WASHER INSTALLATIONS

Face of Mill	Nominal H. P. Rating of Motor	Nominal H. P. Per Inch of Face
30 inch	50	1.66
36 "	40	1.1
4—48 "	250	1.3
4—40 "	150	0.94
3—60 and 1—36 inch	250	1.15

Any engineer would be justified in remarking the apparent inconsistency, although all the mills may be consistently equipped. The table does not indicate diameter of rolls, nor grade of material. The data do not indicate the friction ratio, nor the distance between rolls.

Can we have a rule, applying correctly, based on the length in inches of the face of the roll? Can we have a rule, applying correctly, based on the nominal h. p. rating of a motor?

This committee believes that neither question can be answered in the affirmative. Such rules must be general or be so liberal that to equip with motors safely those mills that do the hardest work, all other drives will be inefficiently over-supplied with power.

The committee believes that such rules have not been followed in general, as data it has indicate some mills equipped with as low as 0.695 nominal rated h. p. per inch of roll face, and other similar mills with as high as 1.39 nominal rated h. p. per inch of roll face.

The committee is confident that many engineers directly associated with the rubber industry have studied the basic problem and that they personally were responsible for the correct motor equipment of their mill lines.

All of the foregoing concentrate on that one phase of motor selection, that phase which determines the peak load capacity which must obtain in the motor. If this were the only issue then the problem would be solved by simply selecting a motor able to meet this demand. But following the process of disintegrating further shows clearly the other factors that must be considered.

That portion of the initial operations which produces high peak loads, is a part of the initial operation load cycle. For that brief period while the "chunk" is passing through, the peak load obtains. During the remainder of the cycle the machine is empty. The load valley is low. In the initial operation the load varies from a minimum of friction load only to the maximum peak load. The thermal capacity requirement of the motor is correspondingly reduced.

Following the disintegrating process further, we find that after the initial operation, of passing through the crude dirty chunks, the now partially disintegrated material is passed through the mill a number of times, this being continued until complete disintegration has been accomplished. This portion of the process must be considered in conjunction with the initial portion of the process in order to determine the mean load value.

The maximum peak load that obtains during the process following the initial process, is approximately 50 per cent of the maximum peak load of the initial process, so if the motor has peak load capacity to handle the initial process peak load we need have no further concern on peak load capacity. But this lower peak load that obtains after the initial process, is a factor in determining the mean load; in determining the thermal capacity requirement of the motor; in determining the basis for efficiency and power factor selection.

An analysis of the actual conditions will show:

1. Abnormally high peak loads, few in number and each of short-time period.
2. Abnormally light-load short-time periods.
3. A mean load that does not exceed 30 per cent of the probable maximum peak load.

(Note) Please bear in mind that this suggested analysis is to be on a basis of one washer room line and do not confuse it with the load factor of an entire plant.

The committee considers this a problem. Is it possible to equip this disintegrating mill line with motors without sacrificing efficiency and power factor and at the same time maintain that large important factor of electric application, namely, flexibility of power application?

It is reported that in tire mills, one horse power is required per tire per day. If this is correct, is it a high tax to place upon the output? If so, can it be decreased?

The extreme flexibility of electric power application has been probably the largest factor in popularizing its use in the rubber industry. Has the flexibility

been extended beyond a reasonable and efficient point? Have mill lines been split up into such a large number of units for production efficiency at a sacrifice of electrical efficiency, that in some instances may not be warranted? This committee does not imply in any manner that such is true. It simply asks the question.

The power requirement as indicated by reported connected load statistics is stupendous. It is so prodigious, that we feel that only by close cooperation between the electrical engineer and the plant production department, weighing together the advantages and disadvantages of segregating here or grouping there, can electrical efficiencies obtain. This must be evident to all.

Where a production efficiency is to be gained at a sacrifice of power efficiency and where this anticipated gain in production efficiency would be less than the resultant losses in power, so that the net result would be a loss, the fact should be recognized and a compromise made that will permit of production on a reasonably efficient basis, with the power application on a similarly efficient basis with a net result of gain.

Where a production efficiency is to be gained at a sacrifice of power efficiency, and where the anticipated gain in production efficiency would be in excess of the power losses, there will as a rule be no question of compromise involved. The net result would be gain, and it is obvious that the engineer would cooperate fully with the production department.

In motor selection the foregoing should be determined definitely so that the engineer may know the operating requirements of that specific department of that specific plant. That point being determined he then has at least two possible factors that will help him to select motor equipment efficiently; these factors are as follows:

1. The adaptability of a signal system to guard against abnormal peak loads. The adaptability of a protective device to stop the mills should the operator disregard the signal.

2. The practicability of placing a number of washers (disintegrating process mills) all on one line, and obtaining the benefit of the law of average, and also the practicability of driving those mills which are contributory to the washing process on the same mill line.

The first type of contributory mill to consider would be the *sheeting mill.* The purpose of this mill is explained in the early part of this paper. This mill, as a rule, is fitted with one fluted roll and one smooth roll. Disintegrated rubber is fed into the mill and the material worked to form the crepe-like sheets.

That high peak loads comparable to the disintegrating mill do not obtain, is readily appreciated. In fact the peak load requirements of the two classes of work, contrast strongly. The highest probable peak load on a sheeting mill is approximately one quarter of the probable peak load, on a washer mill used for disintegrating. The mean load on a sheeting mill approaches the probable peak requirement of this type of mill more closely than the mean load of a disintegrating mill approaches its probable peak requirement. On some installations the probable mean load of a sheeting mill may be as high as 60 per cent of the probable peak load requirement.

A combination then, of the washers used for disintegrating and the washers used for sheeting would promote efficient motor equipment, due to the fact, that the probable combined peak load would be proportionately lessened, and the probable mean load would be proportionately increased.

The next mill that could be considered as contributory to the washing process, is the breaking-down mill. The propriety of advocating the possibility of grouping this type of mill with the washer division may be questioned by many. It may be impracticable in some plants. This suggestion is made here in the hope that it may be helpful to some. Also in many plants the accounting schedule includes the breaking-down process as a function of the washing department.

The breaking-down mill is practically identical to a "warmer" mill, which will be described in a later section of this paper. The rolls on this mill are smooth, and heated. The crepe-like sheets are fed into this mill for the purpose of breaking down the granules, or the coagulated structure, and producing in its place a plastic, tenacious coalescent mass.

A study of the work to be done indicates that:

1. Peak loads are probable.

2. That the manner in which the operator feeds the material into the mill will have a direct bearing on the degree of peak load that will occur.

3. That the peak loads will be of appreciable time duration though gradually decreasing due to the fact, that as coalesence takes place, the mixture adheres to the rolls and some pressure is therefore always evident with this material between them; and also due to the frequent cutting off, and re-feeding by the operator.

4. Although peak loads will and do obtain on any rubber mill, the operator by using a small amount of judgment in feeding and in re-feeding, and by starting the charge at one side of the mill, and permitting it to feed across the face of the roll, can, without sacrificing efficiency in production, control the value of the peak loads within reasonable limits on breaking-down mills.

The probable maximum peak load of the breaking-down mill is approximately 60 per cent of the probable peak load of the initial process of the disintegrating mill, and the probable mean load on a breaking-down mill is approximately 44 per cent of the probable peak value. We now should be in position to condense our analysis as follows:

a. *Initial disintegrating.* Severe and sudden shocks. High peak loads of short duration. Intervals of friction load only, light load. Low, mean load factor. Short-time operation.

b. *Continued disintegrating.* Sudden shocks. Peak

loads of greatly reduced value. Fewer within a given time. Fewer intervals of friction load only. Higher mean load factor. Protracted time operation.

c. *Coagulating.* Peak loads of relatively low value. Fairly high mean load factor. Protracted time operation.

d. *Coalescing.* Sudden shocks. Peak loads of appreciably lower value than those obtaining during initial disintegrating and controllable by the operator. Few intervals of friction load only. Fairly high mean load factor.

(a) and (b) cannot as a rule be separated. (b) is usually a continuation of (a) on the same mill. But, with a number of mills performing disintegrating operations at one time on one mill line the maximum peak of the mill line will not be equal to the product of the peak load of one, times the number of mills in operation. Further, as it is not probable that all mills will be empty at the one time, the mean load will be higher.

If (a) and (b) operations can be combined with (c) all on one line the probable peak load will be appreciably less than the combined maximum peak loads of separate units. If to this can be added the (d) operation a further saving can be effected.

This committee believes that it is not advocating any departure that differs from practise followed by many, but that probably the subject has not been heretofore presented for discussion to a body of men outside of an industrial organization.

The committee submits for consideration the following basis of motor selection for washer mill application:

a. Group as many portions as production efficiency will permit, of any one general process into one mill drive. Preferably group, where practicable, portions whose load characteristics contrast.

b. Determine the probable reasonable peak load demand that will obtain in this group arrangement, with a defined understanding with the production department, what peak load will be considered as reasonable, based on a defined kind of stock, methods to be followed by operators to prevent abuse, the defined peak load value that will give a signal to the operators, and the peak load value which if exceeded will cause the protective device to stop the mill line.

c. Determine the probable mean load that will obtain in this group arrangement.

Then, select a suitable motor of:

1. Ample ability to carry through the peak load.
2. Sufficient thermal capacity to carry the mean load, with as high efficiency, and high power factor characteristics at this mean load as practicable.

A plan of this, or of comparable nature, should provide ample size of motor and eliminate any necessity for oversize of motor. It should also give to the rubber industry that honor of not only being the largest individual user of electric power, but also the most conserving user of electric power.

The grouping as suggested in paragraph (a) should provide a relatively high mean load factor per motor. This should result in a definite known efficiency for each drive. This feature is in contrast to data that show us the load factor of an entire plant, in per cent of nominal h. p. connected load. The power factor of an entire plant can be determined, but the electrical efficiency can not be determined from such data. The load factor of the entire plant in percentage of nominal h. p. connected is the combined mean load on all motors. Some motors may be underloaded and working at low efficiencies. Other motors may be overloaded and working at low efficiencies. Others may be operating under an average load condition that represents satisfactory efficiency.

The efficiency of the electrical equipment cannot be determined by the ratio of electrical input of an entire plant, and the nominal h. p. connected load, but if each application is analyzed in its entirety and motor selection is based on this analysis, each mill drive then will not only be supplied with ample motor equipment to carry on production, but it also will perform that work with high electrical efficiency, and will be a credit to the engineer of selection.

Mixers

Pure Rubber to Rubber Compound

The process up to this point has not changed the physical properties of the rubber. If these properties could not be changed, rubber would be of small value to humanity. Chemical changes can be made within the mass, with the result, that the otherwise useless mass becomes a product that is applicable to many uses. This process of chemical change is a function of mixing, compounding and vulcanizing.

Mixing sulphur with pure rubber, together with the application of heat and pressure, is an essential of vulcanizing. Mixing of other ingredients in addition to sulphur is essential to produce diversified product. The specific use to which the rubber will be put, determines the nature of the ingredient or ingredients used. Every ingredient added produces a chemical change in the rubber to enhance the value of the resultant compound, for that specific commodity of which it will be an important adjunct. In fact the importance of the rubber, and even the importance of rubber of that specific compound, may be such that without it, the article could not be produced.

Process. The cold plastic mass of pure rubber is thrown into the mixing rolls which are heated to a temperature consistent with the kind of rubber and its ultimate use. It is worked and warmed on the rolls of the mixers until the required plastic consistency essential for compounding is reached. The compounds are added a small amount at a time, the

working process being continued, until there is absolute uniformity of the mass.

The physical properties are now radically changed and the rubber is then sent to the store-room, as green-stock.

Motor Selection

In determining motor size, the operating *temperature* of the rolls should be taken into consideration, as the load on the motor is affected by the temperature of the rolls.

In determining motor size, the *kind* of rubber should be taken into consideration (kind of rubber, in this article refers to geographical source of supply). All other conditions being equal, one specific kind of rubber will produce peak loads 100 per cent greater than another specific kind.

In determining motor size, the fact that cold rubber is *thrown* into the mills, and that it is worked and warmed must all be considered. The cold rubber thrown into the mixing mill, produces high peak loads. This cannot be prevented; but if it is thrown into the mixing mill too rapidly, it produces excessive peak loads. This to a large degree can be corrected, by intelligent feeding, and a signal system.

In determining motor size, it should be noted that during the entire mixing operation the mass is worked. This working produces peak loads of prolonged time duration. The working is that operation where the rubber is cut diagonally from the roll, and re-fed into the rolls. The manner of this re-feeding has a direct bearing on the resultant peak load. This can be controlled by the operator to some extent, by starting the re-feeding at one end of the roll, and permitting the material to work across the face of the roll, and by a signal system which will warn the operator if he or others are feeding carelessly.

In determining motor size, the fact that after the initial feeding of cold rubber, subsequent feedings will be warmed, and in consequence the peak loads of re-feeding will be of lower value than the initial feedings of cold rubber, should be taken into consideration.

In addition to the variables involved in the process, the characteristics of each mill must be considered. Large diameter rolls result in a smaller angle of approaching stock, hence a larger wedging force in proportion. This results in higher peak loads, large bearing pressures, increased friction losses. The ratio of friction between the rolls has a direct bearing on the load demand, and must be included in any analysis of conditions, determining suitable motor size.

The number of mills to the mill line should be considered, taking advantage of the law of average. Where a number of mills are involved on one line, the peak load will not equal the peak load of any one, times the number of mills. The fact that a number of mills may be on one line, some working on one kind of rubber and other mills on another kind of rubber should be considered, as the resultant load will not be the product of the heaviest kind of load, times the number of mills, but will be the resultant or mean peaks of the combined heavy kind of load, and the lighter kind of load.

This committee has reports which indicate maximum peak loads on mixing mills as high as 3.5 h. p. per linear inch of roll face. It has been reported that the following rule has been applied; whether it is in actual use, the committee cannot determine.

Take maximum h. p. per inch of roll face 3.5.

Divide this by the value of the ratio between the normal full load torque rating of the motor, and its pull-out torque value.

Multiply by number of inches of linear roll face.

Answer equals nominal h. p. rating of motor to select.

Assume, pull-out torque of motor $2\frac{1}{2}$ times full load rated torque.

Assume, 360 linear inches of roll face.

Then $\dfrac{3.5 \times 360}{2.5} = 504$ h. p., nominal rating, would be the answer, or a nominal rating of 1.4 h. p. per linear inch of roll face.

But, will this apply to every mixing mill line, irrespective of kind of rubber, all diameters of rolls, all ratios of friction between rolls, all temperatures and all pressures that may be involved?

If this is the absolute maximum under the most severe conditions, then the problem becomes one simply of selecting a motor that will surely be large enough and in many installations will be oversize. This committee believes that the problem of the engineer is to equip each mill line with a suitable size of motor as determined from an analysis of the load conditions that obtain on that line.

Another report of record, which this committee received, is as follows:

Mixing Mill Line Loads

Highest 30-minute average peak load	100 per cent
Highest 5-minute average peak load	120 per cent
Highest 1-minute average peak load	155 per cent
Highest instantaneous peak load	215 per cent

This condition could readily obtain on a specific drive on a specific stock under specific working conditions; but, can it be applied as a general rule for the equipping of all mixing lines with motors?

The following list of installations is submitted, not as a basis of selection nor as a basis of approved practise, in that this committee does not have the detail of each installation, but it does indicate that the formula quoted is not followed generally, and it also appears to indicate in some instances at least, that the work to be done by a specific mill line had been taken into consideration.

We are not including the addresses of these installations in that this has no bearing on the situation from

the engineering standpoint. They however include installations in the U. S. from coast to coast, and also Canada, France and Japan.

MIXER LINE INSTALLATIONS

Number and Size of mills	Nominal H. P. Rating of Motor	Nominal H. P. Per Linear Inch of Roll Face
3—40 in., 3—36 in.	150	0.66
3—60 in.	375	1.04
3—60 in., 1—36 in.	250	1.16
3—20 x 60 in.	200	1.11
9—40 in.	375	1.04
5—42 in., 5—60 in.	500	0.98
8—48 in.	200	0.595
6—36 in.	150	0.696
8—60 in.	700	1.46
7—60 in.	450	1.07
6—84 in.	500	0.9925
9—84 in.	800	1.055
4—38 in., 1—44 in., 1—46 in., 1—54 in.,	200	0.675
3—18 x 60 in.	200	1.11
6—60 in., 1—38 in., 1—40 in.	250	0.57
3—32 in., 1—40 in.	150	0.84
2—18 x 48 in.	100	1.04
4—60 in.	300	1.25
4—20 x 54 in.	250	1.155
1—60 in.	100	1.67
2—60 in.	250	2.08
3—60 in.	250	1.39
3—16 x 45 in.	150	1.11
6—84 in.	600	1.19
2—18 x 46 in., 1—18 x 20 in.	150	1.29
2—16 x 48 in., 1—18 x 30	150	1.19
5—14 x 36 in.	100 (reclaiming)	0.555

This list could be continued into hundreds of installations without affecting the conclusion as a whole.

The committee concludes that satisfactory motor size selection cannot be made for each specific mill line by generalizing on limited data. Each mill line should be equipped with motors on an engineering basis; the engineer to have complete data of requirements and to select the size and type of motor which analysis of the conditions that will obtain on that specific drive calls for. No general rule based on nominal h. p. per lineal inch of roll face is applicable. Motors cannot be satisfactorily selected on an arbitrary nominal h. p. rating, which rating means nothing more nor less than that a given motor will carry a certain load continuously with a temperature rise of a certain value.

In general milling operations a uniform even load does not exist on any one mill line. It is not only a varying load, but it is a widely fluctuating load. (This is not intended to apply to the total load of the plant, or to the plant load factor. The plant load factor is the mean load of the entire plant. It is the result of the law of average of the entire plant. We are interested in the equipment of one mill line in that plant and the one mill line is therefore the point of discussion. There is a wide difference). This widely fluctuating load is the problem; how to equip it with motors effectively to maintain production, and also economically.

In a paper presented by Mr. H. C. Stevens of Akron, Ohio, before the Ohio Section of the The National Electric Light Association, meeting of January 21, 1920, is shown an estimated average power factor for four rubber manufacturing plants of 67 per cent. This may include lighting and other unity power factor loads. In any event, can it be improved? A 67 per cent power factor simply means, that all equipment used in producing, transforming and transmitting the power must be of 50 per cent greater capacity than the actual power supplied.

In another table submitted by Mr. Stevens, covering seven rubber manufacturing plants, the maximum demand in percentage of connected load, varies from 39.5 per cent on the lowest, up to 78 per cent on the highest, and on the largest installation shown by the table, the maximum demand is only 89 per cent of the total connected load. This was in August of 1919 at which time the production of rubber was large.

In the same table by Mr. Stevens, we find in six rubber manufacturing plants, an annual load factor based on 8760 hours, for the year 1918, of 30.9 per cent and for the year 1919 on seven plants of 32.7 per cent. Based on a working day of eight hours and a working year of 300 days, this factor would be high, but when compared with other data in the same table it would appear that the working time was in excess of eight hours per day. It would be interesting to know the load factors of the same plants for the year 1920.

A partial analysis or generalizing would indicate the possibility of more efficient motor equipment. Every dollar tied up in oversize or unsuitable motors, and in contributory equipment represents just that much waste. Every unnecessary loss in operation of oversize or unsuitable motors, and in contributory equipment represents just that much waste.

If such waste does obtain we believe that the remedy lies in engineering. Let the electrical engineer look upon each size and type selection as a specific problem. If he has done so in the past, may he continue and with determination analyse even more carefully in the future.

To select a motor large enough, from a given maximum rule, with a constant that is conservative even for the most severe condition, can be the function of anyone, but the selection of a suitable motor for a specific drive, can only result from the careful analysis of complete facts by the engineer. In his analysis, he has, and will continue to consider the following:

a. The mechanical characteristics of each mixing mill. Length of roll face. Diameter of rolls. Ratio of friction between rolls. Width of opening between rolls.

b. *Kind* or preferably *kinds* of rubber on one mill line. Pressures on rolls. Temperatures.

c. That operators can be taught efficient feeding. That this be an understanding with the production department. That a signal system can be used to warn the operator against injudicious feeding. That if the operator ignores the warning and attempts to force, and abuse the mill, a protective device can be used to shut down the mill line. The load on which the signal is to give warning, and the load at which the protective device is to operate would be determined in cooperation with the production department.

d. Grouping of mixer mills to the greatest number permissible on one line, without sacrificing production, and grouping, as far as is consistent, mills on various *kinds* of stock, and obtain that benefit which will result from the law of average, using a constant that the engineer will develop from his own plant operation similar to the typical table of constants given in this paper under the subject of washers.

e. After determining all of the foregoing factors, the engineer will be in position to determine the peak load requirement, and also the mean load for a given period of time. From characteristic performance curves he will select that motor which has sufficient maximum torque capacity to handle the maximum torque requirement of that specific mixer mill line, and will select that type of motor which will not only do this, but which also will have sufficient thermal capacity to carry the mean load, and will do this efficiently and with a minimum of reactive current.

Atmospheric Conditions of Mixing Rooms. Mixing is usually attended by dust of the compounding ingredients. Some is highly abrasive, some is only slightly so, in any event it is preferable to so plan the installation that this dust cannot prove detrimental to the motor bearings.

The situation has been somewhat accentuated since the advent of organic accelerators, ingredients that are added to hasten vulcanization, as this dust is frequently injurious to health. Probably the best solution is an installation of a dust collecting, and ventilating system with a motor-operated blower to remove fumes and dust, thereby protecting the operators and machinery alike.

In the foregoing the subject has been one of mixing rolls and does not refer to batch mixers or mixing machines.

This committee has no test data applying to the mixing machine and can make no comments with reference to peak load demands.

The manufacturer lists two sizes in their literature as follows:

Size	Batch Capacity Crude Rubber	H. P. of Motor Individual Drive	Average H. P.
3	70 lb.	75	50
9	210 lb.	200	125

This committee would be glad to receive from any engineer any data he can give us with reference to the power requirements of the mixing machine.

Warmers

The green-stock is accounted back to the storeroom from the mixer room and after a "seasoning" is accounted out to other departments, such as calender room, tube room, etc. Warming is the initial program in the various departments where it is used. The warmer mill discussion is closely allied in this paper to that of the mixing mill, in that the machine itself is practically identical to a mixing mill and the motor problem is similar.

Process

The cold green-stock is thrown into the warmer to warm the stock to render it soft and pliable so that it can be calendered readily.

In the mixing operation the stock was changed from a plastic condition to a tough, resilient product.

In addition to warming, the stock is worked on the warmer rolls to affect its consistency throughout uniformly.

Motor Selection

The fact that warmer mill is practically identical to the mixer mill makes all suggestions that apply to one, apply to the other, with two possible exceptions.

1. The cold green-stock thrown into the warmer does, as a rule, owing to its less plastic nature, cause higher peak loads than the cold pure rubber thrown into the mixer.

2. There is less probability of its being practicable to combine on one mill line a number of warmers, or of having warmers on one mill line handling various kinds of stock at the one time. It can be done in many instances, and it is advisable to take advantage of the opportunity wherever practicable.

In evidence that in some plants at least, a general rule is not applied in motor size selection, we add the following table:

Size of Warmer	Nominal H. P. Motor Rating	Nominal H. P. Per Linear Inch of Roll Face
1—18 x 36 in.	40 h. p.	1.11
1—16 x 36 in.	25 h. p.	0.695
1—18 x 36 in.	50 h. p.	1.39

Conclusions

The basic idea of this committee is to equip rubber mill machinery with motors on an engineering basis. The committee believes that with the large amount of power involved more efficient motor equipment can obtain in many plants if we have a plan to provide the proper cooperation.

The committee concludes that many engineers have their own plans that they execute faithfully and with success.

The committee does not advocate a plan, simply

on account of the plan, but if one can be developed that will be helpful to the engineers in the rubbe industry as a whole, the committee then would favor it and gladly cooperate, not for the success of the plan as a plan, but for the benefit that would result to the engineers of the rubber industry.

Safety Stop

Hazard

The *danger* which is prevalent in the various operations of *general milling* or *basic operations* is due to the tenacious character of rubber in its plastic state.

The operator is very likely at any time to become caught in the folds of the rubber and drawn into the rolls. He may be caught on either hand, or both hands may become entangled. The safety mechanism should be, therefore, of such a nature that if both hands are entangled he can trip the mechanism with his head. The safety mechanism of all machines on any one mill line should be so interconnected that any operator on that mill line may stop the entire mill lines from his own mill should another operator become caught.

Although this is a dangerous condition under which these men must work it has one redeeming feature. The operator does not become caught directly in the rolls. If so then he would be damaged to some extent no matter what device were used for the stopping of the mills. He is caught in the folds of the rubber some several inches from the point of contact of the two rolls.

If a suitable type of safety stop is used and if prompt action is taken either by the operator who is caught, or by one of his companions at an adjacent or nearby mill, or in fact at any mill along that line, it is entirely within reason to obtain a stop sufficiently quick to prevent damage to the individual.

Safe Stopping Distance

The diameter of the average roll is 22 in. A diagram would indicate clearly why the maximum stopping time of the roll must not exceed approximately 40 angular degrees of periphery travel between the time that the man is actually caught and the time in which the mill is brought to rest.

This brings the actual stopping time available from the moment that the safety mechanism is tripped until the mill is actually at rest to about 20 angular degrees of periphery travel. Put this in terms of inches of periphery travel and it gets to that short distance of 4 in. This should be measured by a chronograph in that the eye cannot detect this with a sufficient degree of accuracy.

If a device will stop the mills within 4 in. of travel of the roll periphery it can be depended upon as a rule to prevent damage to the operator.

Suitable Stopping Device

This committee has knowledge of only one basic way in which this stopping can be obtained.

The means for this service consists of a device which will disconnect the prime mover, which is a high inertia load, from the driven mill line, which is a low inertia load, and which device will simultaneously apply a brake to the driven load.

With devices of this nature sufficiently quick stops can be obtained without any probability of damage to the equipment through the shock of this quick stopping. Second and most important the stopping can be done quickly and with sufficient speed to consider such a device as a safety stop—not simply a stop.

Clutch brakes are made in both the magnetic, and the air type. The magnetic clutch brake has been most generally used. It is an easy matter to "tie in" the magnetic clutch brake type with the electrical system. It also undoubtedly has that advantage of being most simple in structure.

Many schemes have been tried which do not contemplate disconnecting the motor mechanically from the mill line.

Plugging the motor to reverse it to bring it to a stop has been tried, but this has never met with any degree of success. Even were it successful in stopping quickly it would still have the disadvantage that it depends on an outside source of supply for its ability to stop the mills at a critical moment. This alone would militate against it.

The one other method that has been tried to some extent and which is the only one so far that we can find that begins to approach a safety stop, is that one which contemplates the opening of the motor circuit and the applying of a magnet-operated mechanical brake.

However, when it is considered that at least 85 to 90 per cent of the stored energy of angular rotation of the combined motor and mills is in the motor, it can readily be appreciated what a large size this brake must be in order to absorb the large amount of stored energy that is in the motor, in order to bring the motor and the mills to a stop, that begins to approach that stop which would be considered a safety stop in every sense of the word.

We have found for example, on a 50-h. p. motor where the normal motor torque is 510 lb-ft., that the torque required to bring mills to a stop within a travel of 6 in. of the periphery of the rolls means an energy absorption equal to 2380 lb-ft. This means a ratio of required torque on stopping to normal torque of 4.65.

On a 200-h. p. motor where the normal motor torque is 2050 lb-ft. the torque required for 6-in. stop is 10,700 lb-ft. or a ratio of 5.2 to 1.

On a 500-h. p. motor, the normal motor torque lb-ft. is rated at 5,100, whereas the torque required for a 6-in. stop of roll periphery travel is 15,500 lb-ft. A ratio of 3 to 1.

The above refers to motors operating at a speed of 514 rev. per min.

With a roll diameter of 22 in. and a roll speed of 18 rev. per min. a 6-in. stop on that roll would require that the motor be stopped in 2½ revolutions, or in about 0.58 second.

Complete consideration of these figures will indicate to the engineer the size of brake that would be required to bring the motor and the mills to rest within a time lapse that would be safe. It will also show the heavy strain that must be imposed on the rotor structure, in that the mechanical brake must be attached to the rotor shaft, whereas practically all of the energy of rotation is in the rotor proper.

Stopping Test Results

The following tests were made on a mill drive including two Farrel 22 x 60, back roll 23.07 rev. per min. Front roll 18.03 rev. per min. Friction ratio 1.27.

The motor was a Westinghouse type C. W. 1002, 250-h. p. 580 rev. per min.

Tests were made both with a device which was arranged for disconnecting the motor mechanically from the mill line and applying a brake, and with the other device arranged for opening of the motor circuit and applying a brake to stop both motor and the mills.

Stopping with no safety device the roll travel was 240 in.

Stopping by disconnecting the motor mechanically from the mill line and permitting the mill line to come to rest against its own friction the travel of the front roll was 103 in.

Disconnecting the motor from the source of supply electrically and applying the brake to stop the motor and the mills the travel of the front roll was 40 in.

By using the combination which disconnected the motor mechanically from the mill line and applying the brake to the mill line only, the travel of the front roll was 8 5/8 in.

The above test was conducted with all of the mills empty. This would be the worst condition that could obtain for the reason that the friction on the mill line would be low. This condition could not obtain at a time when safety stop would be required for the reason that no one is likely to be caught under this condition.

The worst condition under which an operator can be caught is that one which obtains with only one mill operating and all of the other mills idle. This presents an opportunity for an operator to be caught and at the same time with a minimum of load on the mill that could be depended upon to assist in quick stopping.

The following test data were obtained with one mill loaded, the load on the motor being 130 h. p.

Stopping naturally by simply disconnecting the motor from the line electrically and applying no outside force the front roll travel was 75 in.

By disconnecting the motor from the mill line mechanically and applying no brake to the mill line, the mill lines come to rest with a travel of the front roll of 16 in.

By disconnecting the motor from the source of supply electrically and applying the brake to stop the motor and the mill line simultaneously the front roll travel was 16⅜ in.

By stopping with the device which disconnected the motor from the mill line mechanically and applied a brake to the mill line only, the front roll travel was 4⅛ in.

Compensation

This is a very important question. It is one where even human life is involved. Some years ago before safety stops were used as generally as today every mill had its quota of cripples, and even today you will find an unusual number who were injured through being caught in this plastic material and drawn into rolls.

The Industrial Commission as a rule favors the worker, and the employer must pay heavy indemnities varying in many States from approximately $120.00 minimum for loss of the ring finger at the second joint up to a maximum of approximately $5,000.00 for the loss of an arm at or near the shoulder. In addition to this the employer must pay all doctor and hospital bills.

Further, there is a loss to the community of the man's idle time.

On the other hand,there is no question but that it would be much more fitting had the accident never occurred. We question if there is any other one feature on which the engineer can be more careful than in the selection of suitable accident preventive devices in connection with this class of work.

Recommendations

It is the recommendation of this committee that the most suitable manner in which safety stops can be electrically connected is in such manner that when the safety mechanism is operated the entire mill line drive including the motor will come to rest; whether or not the motor comes to rest as quickly as the mill line is not important, but that it also be so interlocked with the motor control system that even the motor cannot again be restarted until all safety devices have been placed in the "run" position, so as to have assurance that all workmen are clear of the mills, is important.

We favor also an arrangement, or combination of arrangements, of such nature that the operator who has charge of restarting of the mills cannot restart the mills at least, even though he may be able to start the motor, excepting from such location that the entire front of the mill line is visible to him, so that he can be assured that all is "clear" before he actually puts the mills in operation. We believe this to be important as it would eliminate entirely possible accidental restarting of mills.

Phase Compensation*

With Special Reference to Polyphase Motors

BY VAL. A. FYNN

Consulting Engineer, Wagner Electric Mfg. Co., St. Louis, Mo.

In a series of articles which appeared in the *Electrical World* in 1913, the author dealt, at some length, with phase control in general, with phase compensation in synchronous motors, and with the only method of controlling the power factor in single-phase motors with shunt characteristic which has, to date, become of practical value; but other means of controlling the phase difference in nonsynchronous single-phase motors are known and these will now be considered before dealing with phase control as applied to non-synchronous polyphase motors.

All the figures show two-pole machines.

7. Controlling the Phase Difference in a Single-phase Motor with Shunt Characteristic by Changing the Phase of the Exciting e. m. f.

The method of controlling the power factor of a single-phase motor which has been applied in practise

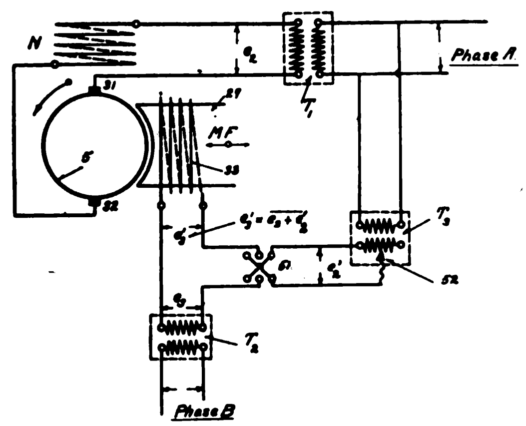

Fig. 33—Neutralized and Compensated Shunt Conduction Single-Phase Motor Operated From a Two-Phase Supply

with the greatest success consists in changing the phase of the exciting e. m. f. relatively to the phase of the working e. m. f. This method is illustrated in Fig. 33 as applied to a neutralized, single-phase, shunt, conduction motor. The armature circuit 31, 32 of this machine is connected to one phase of a two-phase supply, while its exciting winding 33 is connected to the other phase. Normally, there would, therefore, be a quadrature relation between the working and the exciting e. m. fs. and all but phase coincidence between the former and the motor or exciting flux. This condition would make the back e. m. f. in the armature circuit practically cophasal with the working e. m. f. and would result in a poor power factor because of the impedance of the armature circuit. To correct this condition, it is now usual to change the phase of the e. m. f. applied to the terminals of the motor field exciting winding 33. In Fig. 33, this is done by impressing on the field winding 33 an e. m. f., one component of which is derived from phase *B*, while the other is taken from phase *A*. Almost any degree of phase control can be obtained in this way, simply by changing the magnitude of the component derived from phase *A*.

Now, the real object of changing the phase of the exciting e. m. f., and thereby changing that of the exciting flux, is to change the phase of the back e. m. f. in the armature circuit. The magnitude and phase of the armature working current are determined by the magnitude and phase of the vectorial difference

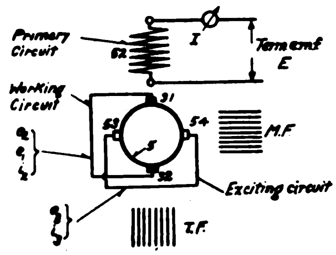

Fig. 37—Self-Excited Single-Phase Shunt Induction Motor

between the working and back e. m. fs. and by the time constant of the armature circuit. In applying the phase-controlling method under reference, one aims to so place the phase of the vectorial difference between working and back e. m. fs. that, notwithstanding the time constant of the armature circuit, the phase of the armature current will, nevertheless, closely approach that of the terminal e. m. f. and will not depart too far from that of the motor or exciting flux.

A close coincidence between current and terminal e. m. f. of course spells high power factor, but it is inadvisable to push phase compensation so far as to produce a material phase difference between armature current and motor flux, for the reason that the greater this difference, the smaller will be the torque per ampere.

The application of this same principle to the self-excited, single-phase, shunt, induction, commutator

*Presented before the St. Louis Section A. I. E. E., October 27, 1920.

This paper supplements a series of articles by Mr. Fynn, published in the *Electrical World*, July 5, 12 and 19, 1913, which had special reference to single-phase motors.

motor shown in Fig. 37, is of more practical interest because not requiring a polyphase supply, and is illustrated in Fig. 38. It is known that such a machine produces its own exciting e. m. f. e_3 and that the phase of the latter is displaced by about 90 degrees with respect to the terminal, or working e. m. f., as shown in Fig. 54. This being so, the phase of the effective

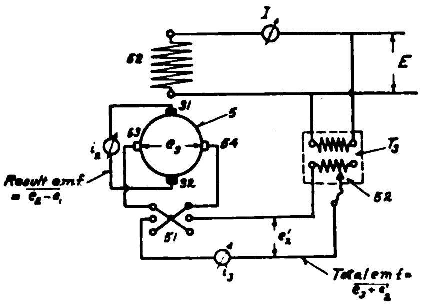

FIG. 38—SELF-EXCITED SINGLE-PHASE INDUCTION COMMUTATOR MOTOR WITH SHUNT CHARACTERISTIC AND ARTIFICIAL PHASE COMPENSATION

exciting e. m. f. along the axis 53, 54 can, in this case, be changed by injecting into the circuit along said axis an e. m. f. of same phase as that of the supply.

The complete phase diagram of the motor shown in Fig. 37 is seen in Fig. 55, and it is thought that a short discussion of this diagram will be of use in elucidating some phase-controlling methods not heretofore discussed. In order to avoid undue complication of Fig. 55, some of the vectors have been omitted.

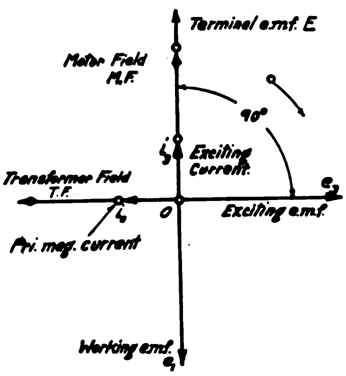

FIG. 54—APPROXIMATE PHASE DIAGRAM OF A SINGLE-PHASE SHUNT INDUCTION MOTOR, WITH SELF EXCITATION

One point to which it is desired to draw particular attention is the presence in the exciting circuit 53, 54 of the small e. m. f. $G J$, the effect of which is to shift the phase of the effective e. m. f. $O J$ in the exciting circuit, and therefore the phase of the exciting flux $O L$ and of the back e. m. f. $O M$, in a direction to *improve* the power factor of the machine. The e. m. f. $G J$ which provides this compensating feature in the motor shown in Fig. 37 is generated in the rotor conductors along the axis 53, 54 by rotation of said conductors in the leakage field produced by the armature ampere turns along the rotor axis 31, 32. Without this e. m. f., this type of motor would be of no practical utility. It is interesting to observe that, independently of the magnitude of the rotor leakage flux, and therefore of the rotor impedance, this self-compensating e. m. f. is of such magnitude, *at synchronism*, as to eliminate entirely the effect of the rotor impedance. Because this e. m. f. is dependent on the speed of the rotor, it diminishes as the slip of the motor increases and at sub-synchronous speeds, the rotor impedance along the armature axis 31, 32 is not entirely compensated for by the effect of the e. m. f. in question. The power factor of the motor shown in Fig. 37 is, nevertheless, smaller than unity, even at synchronism, for the reason that the self-compensating e. m. f. $G J$ does not, at that speed, produce a leading current in the rotor along the axis 31, 32 and does not, therefore, compensate for the lag in the primary 52, which lag is due to the magnetizing cur-

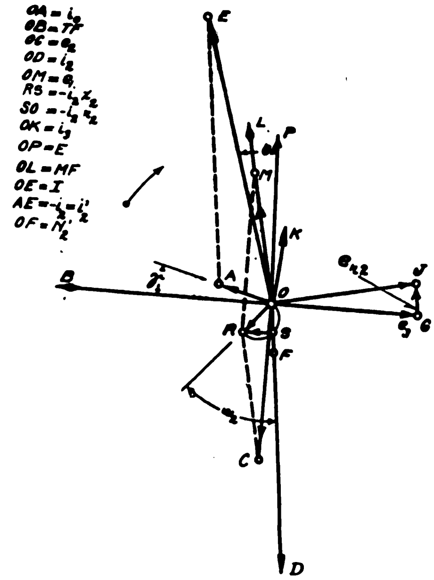

FIG. 55—EXACT PHASE DIAGRAM OF A SELF-EXCITED SINGLE-PHASE SHUNT INDUCTION MOTOR

rent circulating in the stator inducing winding. At super-synchronous speeds, the self-compensating e. m. f. does cause the secondary current to lead the working e. m. f. in the rotor axis 31, 32 and thus does, at least partly, compensate for the magnetizing component of the stator.

Referring back to Fig. 33, it will now be apparent that no such self-compensating feature exists in that machine, with the result that such a motor would be quite useless without the application of external phase-controlling means and that the whole phase displacement of the back e. m. f. must be brought about by external means.

The other point in connection with Fig. 55 to which particular attention should be drawn, is the fact that within the working range of the machine, the phase of the working current $O D$ does not materially depart from the phase of the working e. m. f. $O C$, and the reactance drop $R S$ is substantially in quadrature with the self-compensating e. m. f. $G J$.

8. Connecting a Condenser in Parallel with the Terminals of a Motor

It is a question whether this method should be included in a discussion of means for controlling the phase difference in single or polyphase motors, for the reason that it changes nothing within the motor it-

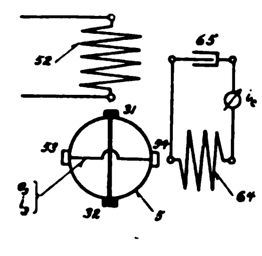

Fig. 56—Self-Excited Single-Phase Shunt Induction Motor with a Condenser in Inductive Relation to the Field Circuit

self, but merely compensates for the effect of the motor as a whole on the circuit to which it is connected. This arrangement calls, at equal voltages, for condensers capable of handling a current of a magnitude equal to that of the reactive component of the total current absorbed by the motor. Such condensers can be connected to the terminals of the machine either directly or with the interposition of step-up transformers, and they must be built for the same frequency as the motor. This method is not looked upon as a practical one, for the reason that such condensers as are available for this

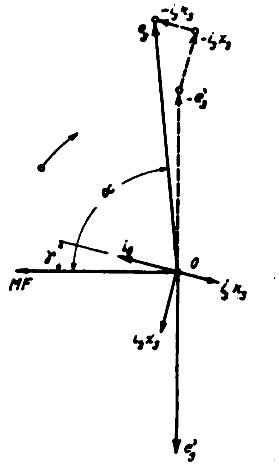

Fig. 57—Phase Diagram of Field Circuit of Motor of Fig. 56 with Condenser Disconnected

purpose are still prohibitive as to price. Dynamic condensers may be, and sometimes are, used in the same way, but here again the question of price interferes in most cases.

9. Controlling the Phase Difference in a Single-Phase Motor by Connecting a Condenser in Inductive Relation to the Field Circuit

One such arrangement, which is diagrammatically shown in Fig. 56, falls strictly within this investigation and is quite interesting. If it has not come within the range of practical politics, it is for the reason that it relies on condensers.

Figs. 57 and 58 show how the phase-controlling device of Fig. 56 operates. The phase diagram of Fig. 57 refers to any kind of a transformer, the secondary of which is on open circuit. The e. m. f. applied to the primary of this transformer is e_3, the magnetizing current is i_3, the transformer flux is $M F$ and e_3' is the secondary e. m. f. The terminal e. m. f. e_3 must equal and oppose the vectorial sum of an e. m. f. of same magnitude as e_3' induced by $M F$ in the primary winding, of an e. m. f. $i_3 x_3$ induced in the primary by the leakage flux due to i_3 and of an e. m. f. equal and opposed to the ohmic drop $i_3 r_3$. The result is that while the phase difference between $M F$ and e_3' is 90 degrees, that between the flux $M F$ and the terminal e. m. f. e_3 is less than 90. Now, in the ordinary self-excited, single-phase, in-

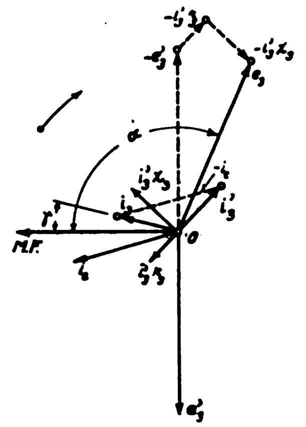

Fig. 58—Phase Diagram of Field Circuit of Motor of Fig. 56 with Condenser in Circuit

duction motor, with shunt characteristic, such as shown in Fig. 37, the open circuit transformer conditions illustrated in Fig. 57 obtain along the motor field axis 53, 54 with this peculiarity that the e. m. f. impressed on the primary of this transformer is generated in the machine itself by rotation of the rotor conductors in the transformer field appearing along the axis of 52. In the ordinary machine, there is no secondary winding in the axis 53, 54, but as long as the conditions are considered in which this winding is on open circuit, it is, of course, immaterial whether said secondary exists or not. Suppose now, that a secondary winding such as 64 of Fig. 56 is placed in inductive relation to the primary, which is the rotor winding 5 along the axis 53, 54, and that this secondary is closed on a condenser 65. The changes brought about by this addition are shown in Fig. 58 where it has been assumed that the condenser 65 will take the leading current i_c when e_3' is impressed on its terminals. Since the flux $M F$ must be preserved in order to counterbalance the e. m. f. impressed on the terminals of the primary 5, the latter will take a current i_3', equal

to the vectorial sum of the magnetizing current i_3 and of another current equal and opposed to i_c. This brings about a very material change in the phase of the current in the primary 5 along the axis 53, 54, with the result that the ohmic drop and the reactance voltage in this winding also change their phases. The e. m. f. impressed on said winding, which in Fig. 56 is the exciting winding of the motor, must, as before, equal the vectorial sum of e. m. fs. equal and opposed to e_3', $i_3' r_3$ and $i_3' x_3$.

Because of the changed phase relations just referred to and brought about by condenser 65, the phase difference between the voltage e_3 at the terminals of the primary 5 and the flux $M F$ will be greater than 90 degrees, instead of less than 90, as in Fig. 57.

Referring now to Fig. 55, it is seen that the effect of the self-compensating e. m. f. $G J$ is to increase the phase difference between the exciting e. m. f. proper which is e_3 and the motor flux $O L$. From this, it appears that the condenser 65 of Fig. 56 produces the same result, although it does so in a totally different manner.

In the motor of Fig. 37, ohmic resistance in the rotor along the axis 53, 54 is detrimental to the power factor in that it decreases the phase difference between the exciting e. m. f. e_3 and the motor flux $M F$, as may be seen from Fig, 57. By adding the winding 64 to this machine and connecting it to a condenser 65, the effect of ohmic resistance in the rotor axis 53, 54 is reversed, as is shown by Fig. 58.

The addition of the winding 64 and the condenser 65 of Fig. 56 may also result in a change in the speed of the motor. Because of the altered phase relations within the rotor exciting circuit, brought about by the use of the condenser, the same flux $M F$ can be produced with a smaller exciting e. m. f. e_3 as appears from a comparison of Figs. 57 and 58. Conversely, if the exciting e. m. f. remains unaltered, it will produce a larger $M F$ and thus bring about a material reduction in the speed of the motor. The conditions indicated in Fig. 58 will actually be met by such a reduction in the motor speed as will reduce the exciting e. m. f. to a value which will generate a motor field of a magnitude sufficient to produce, at said lower speed, a back e. m. f. of the required value.

The condenser 65 must be built for the same frequency for which the motor is made and may, of course, be connected to the winding 64 with, or without, the interposition of a step-up transformer. If the winding 64 is located on the stator in an axis other than that of the motor field, then the effect of the condenser 65 will be twofold. A winding so located can always be replaced by one in line with the motor field and another in line with the armature axis, each being connected to a separate condenser. The effect of the winding in line with the motor field axis will be as just described, while the other winding will simply compensate for the magnetizing component in the stator winding 52.

The fact that the phase angles and the magnitude of some of the e. m. fs. have been exaggerated in Figs. 57 and 58, in order to produce clear diagrams, does not vitiate the conclusions except as to degree. It should further be noted that the value of the current in the primary 5 along the axis 53, 54 has been kept the same in the two diagrams. It is clear that this current may, in practise, be given any permissible value. If the phase of the primary current is made to lead that of the motor flux by 90 degrees, then the magnitude of the reactance voltage exerts a maximum, and that of the ohmic drop a minimum, influence on the phase difference between $M F$ and e_3. In case the primary current is made of opposite phase to the motor flux, the influence of the ohmic drop becomes a maximum and that of the reactance voltage a minimum.

While the action of the condenser 65 has been explained with particular reference to the self-excited, induction, commutator motor with shunt characteristic, this method of phase control is applicable to other types of motors, for instance, to the corresponding squirrel-cage or slip-ring machine, where it operates in exactly the same way.

10. Controlling the Phase Difference in a Single-Phase Motor with Shunt Characteristic by Introducting into the Armature Circuit an E. M. F. of a Phase Opposed to That of the Reactance E. M. F.

The injection of a compensating e. m. f. into the exciting circuit as shown in Fig. 38 and the use of a condenser in inductive relation to the exciting circuit as shown in Fig. 56 both aim to control the phase difference in the machine in what appears at first sight to be a somewhat roundabout way. A more direct method is that which consists in injecting into the armature circuit an e. m. f. which will oppose the reactance e. m. f. in that axis. This proposition can also be looked upon as a direct means for changing the phase of the resultant back e. m. f., in which case, the injected e. m. f. is dealt with as a component of the back e. m. f. While theoretically simpler than the methods shown in Figs. 38 and 56, yet this scheme has little practical value in connection with single-phase motors. In the case of a machine such as that of Fig. 33, it is as easily applied as the one which achieves the result by altering the phase of the motor field. The reason for this is, however, the availability of a polyphase system of distribution. On single-phase circuits, the application of this scheme would require the addition of a phase converter or similar device. There are, however, other serious drawbacks to this arrangement; it adds to the resistance of the armature circuit and thereby lowers

the efficiency of the machine and it also adds to the reactance of that circuit, thus making it necessary to inject a compensating e. m. f. which will not only take care of the reactance of the rotor circuit along the armature axis, but also of the reactance of the source from which the compensating e. m. f. is derived. The addition of this external reactance is also unfortunate in that it makes it necessary to change the external compensating e. m. f. with changing load if the power factor is to be kept constant.

11. Controlling the Phase Difference in Single-Phase Induction Motors with Shunt Characteristic by Injecting a Unidirectional e. m. f. into the Induced Member

When a single-phase induction motor of the type shown in Fig. 37, or of the squirrel-cage type which is its equivalent, is in operation the resultant flux in the machine is nearly constant in magnitude and revolves in synchronism with the line frequency; this flux is produced in part by the inducing, and in part

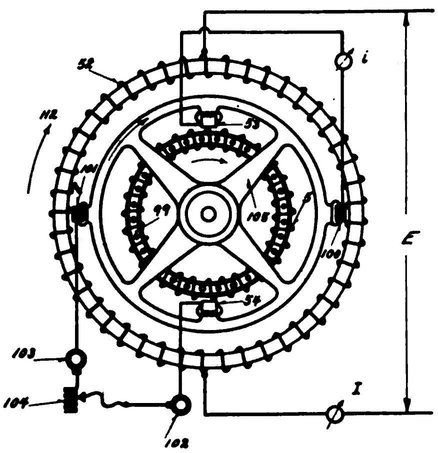

Fig. 59—Single-Phase Shunt Induction Squirrel-Cage Motor With Unidirectional Excitation (Stationary Inducing Member)

by the induced member. To fix ideas, consider a squirrel-cage, single-phase motor with stationary inducing member, as shown in Fig. 59. The inducing winding 52 is connected to the supply, and the rotor, provided with the squirrel-cage winding 99, revolves in a clockwise direction at a speed slightly below the synchronous. At no load, the rotor has only to overcome windage and friction losses and the slip is consequently very small. The total magnetization of the machine is produced partly by stator, and partly by rotor currents. The former are of line frequency, while the latter are of line plus rotor speed, and of slip frequency. When the magnetization produced by the stator is at its maximum, then the magnetization produced by the rotor is coaxial with, but opposed to, the former and the axis of the resultant revolving field $R F$ in the motor coincides, at that instant, with the axis of the inducing winding on the stator. One-fourth of a period later, all of the motor magnetization is produced by the rotor and the axis of the revolving field in the motor has traveled through 90 electrical degrees.

This is true whether the motor revolves at a synchronous, or a nearly synchronous, speed. As the rotor speed diminishes, the frequencies of the rotor currents change and thus keep the speed of the revolving flux constant. That component of said flux which is produced by the rotor, and often referred to as the speed component, however, diminishes with decreasing speed which causes the end of the revolving flux vector to follow a more and more elliptical, instead of a circular, path.

Now, if it were possible to produce the revolving flux required by this motor by suitable external means, all magnetizing currents could be eliminated from its stator as well as from its rotor, while the character of the machine could conceivably be left unchanged. The method under reference accomplishes this by means of a commuted winding 5 located on the rotor and brushes 53, 54 cooperating with same.

A direct current introduced into the winding 5 by means of the brushes 53, 54 will produce a unidirectional magnetization, the axis of which, will always coincide with the axis of said brushes, or bear a fixed relation thereto, independently of any movement of the rotor conductors. The method consists in supplying a unidirectional e. m. f. to the brushes 53, 54 and revolving these in the same direction as, and in synchronism with, the revolving flux of the motor, that is, in synchronism with the line frequency. An additional condition for best results is that the axis of said brushes shall, at every instant, coincide with the axis of said revolving field.

In the motor shown in Fig. 59, the revolving flux rotates in a clockwise direction, as indicated by the arrow 112, the rotor necessarily revolves in the same direction and the brushes are, therefore, also rotated in a clockwise direction. The space position of the brushes at any instant is determined by the consideration that when the magnetization produced by the stator is at its maximum, the axis of the revolving flux coincides with the axis of the stator inducing winding 52. At that time, the stator magnetizing current is practically at its maximum and the terminal voltage is zero or nearly so.

When the unidirectional e. m. f. applied to the brushes 53, 54 is of such magnitude as to produce a flux of exactly the same magnitude and direction as that normally produced by the combined efforts of stator and rotor, then all magnetizing currents in stator and rotor will be eliminated. Under these conditions, the stator carries load currents only and these have line frequency, while the rotor carries load currents of slip frequency and a unidirectional exciting current. If the unidirectional excitation is not sufficient, the stator and rotor magnetizing currents are not entirely eliminated. If it is excessive, the machine takes leading

currents, for the reason that in order to balance the terminal e. m. f., it is necessary to dispose of a flux of a given magnitude. The motor current will so adjust itself as to keep said flux constant as long as the terminal e. m. f. remains constant. If the unidirectional magnetization under the conditions named does not produce all of the required flux, then the motor will take enough lagging current to make up the difference, while leading currents will be absorbed if it becomes necessary to reduce the magnetization produced by the unidirectional excitation.

The brushes 53, 54 can readily be revolved at synchronous speed by means of a synchronous motor geared to the brush rocker arm 105.

The unidirectional e. m. f. required for the compensation of the machine can be derived from any convenient source, but Fig. 59 shows one way of deriving said e. m. f. from the motor itself. If the inducing winding 52 is given the form of a commuted winding and brushes

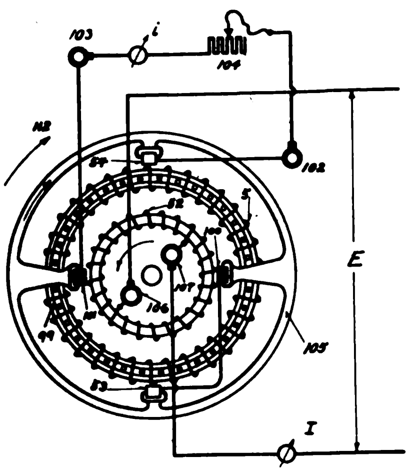

Fig. 60—Single-Phase Shunt Induction Squirrel-Cage Motor with Unidirectional Excitation (Stationary Induced Member)

100, 101 are arranged to properly cooperate with same, then a unidirectional e. m. f. can be derived from said winding 52 and utilized to produce the desired unidirectional magnetization in the rotor. When the brushes 53, 54 revolve, the unidirectional flux they locate revolves with them, and as far as the inducing winding 52 is concerned, it is as if the brushes 53, 54 were stationary and the winding 52 were rotated in a counter-clockwise direction. Under the last named conditions, it would be possible to collect a unidirectional e. m. f. preferably at the neutral points of the winding 52. These neutral points are at right angles to the axis of the field which is coaxial with 53, 54 and the brushes 100, 101 are therefore in the most suitable position to collect said unidirectional e. m. f. The conditions are not changed if the generator brushes 100, 101 and the compensating brushes 53, 54 are revolved without change in their relative positions, instead of revolving the winding 52, and if they are revolved in synchronism with the supply, nothing but a unidirectional e. m. f. will appear at the brushes 100, 101.

In Fig. 60 is shown a motor of the same type as that illustrated in Fig. 59, but in this case, the inducing member 52 revolves, while the induced member provided with a squirrel-cage winding 99 is stationary. The inducing member is provided with slip rings 106, 107 and it is assumed that it rotates in a counter-clockwise direction. With the inducing winding revolving at synchronism, the resultant motor magnetization would be stationary in space; with the rotor running below synchronism, the axis of the resultant magnetization revolves with slip frequency in a clockwise direction, thus the difference in speed between the inducing member and the revolving flux axis is always equal to the synchronous. In order to apply the phase compensating means of Fig. 59, it is only necessary to provide the stator with a commuted winding, dispose compensating brushes 53, 54 on same and revolve said brushes at slip frequency in a direction opposed to the direction of rotation of the rotor. The compensating brushes can be so revolved, for instance, by means of a differential gearing; in which case, they can be carried by the pinion of said differential, while one wheel thereof is driven from the revolving inducing winding and the other wheel is driven from a synchronous motor operated from the supply.

It will be noticed that Fig. 60 has all the elements of a single-phase converter. With the rotor 52 revolving at synchronous speed, stationary brushes, such as 100, 101, when located at right angles to the unidirectional excitation of the converter, determined by the axis of the brushes 53, 54, would be in a position to collect a unidirectional e. m. f. from the winding 52. These brushes will continue to collect such an e. m. f. as long as the difference in speed between said brushes and the winding 52 remains equal to the synchronous and as long as the brushes named are at an angle to the unidirectional magnetization produced in the machine. These conditions are readily secured in the motor of Fig. 60 by fixing the generator brushes 100, 101 in quadrature relation to the compensating brushes 53, 54 and revolving both sets of brushes at slip frequency in a direction opposed to that in which the inducing member rotates. In this way, it is possible to derive the unidirectional compensating e. m. f. from the motor itself.

12. Controlling the Phase Difference in Single-Phase Motors with Series Characteristic

Although most single-phase motors with series characteristic can be built to operate with a power factor near unity at super-synchronous speeds, yet it is sometimes very desirable to operate such machines with a power factor near unity at sub-synchronous speeds, or to run them with a leading power factor

at sub-synchronous or super-synchronous speeds. In order to achieve such results, it is necessary to resort to some method of controlling their phase difference. A number of methods are available over and above the use of condensers, which for the purpose named, can for instance, be connected in parallel with the field winding of the motor.

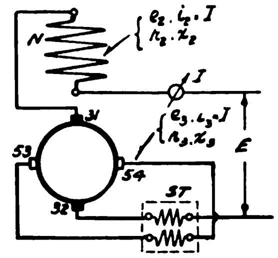

Fig. 61—Neutralized Series Motor With Two Inductively Related Rotor Circuits

One of the practical methods for controlling the power factor of a single-phase series conduction motor, in which at least part of the exciting winding is disposed on the revolving member, is to produce an auxiliary flux along the armature axis and to so select the phase thereof that the e. m. f. generated by rotation of the rotor exciting winding in said flux, opposes the reactance e. m. fs. in the motor circuit.

In order to explain the manner in which this method of phase compensation operates, an ordinary neutralized, series, conduction motor will first be considered. Such a machine is shown in Fig. 61 and the fact that a type has been illustrated in which the field circuit is disposed on the rotor, will in no way alter the conclusions to be reached. Fig. 62 is a phase diagram

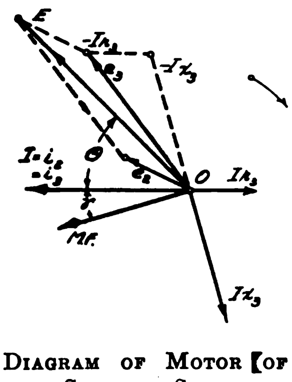

Fig. 62—Phase Diagram of Motor of Fig. 61 When Standing Still

which shows the conditions as they exist when the motor of Fig. 61 is at rest; in which case it is, of course, nothing but a choke coil. It is assumed that the transformation ratio of the series transformer S T is 1:1; so that the exciting current i_3 is practically equal in magnitude to the working current i_2, which, in this case, is the same as the line current I. The working e. m. f. e_2 at the terminals of the armature circuit will lead the armature current by a certain angle as shown, because this e. m. f. must equal and oppose the ohmic drop and the reactance e. m. f. in the armature circuit. The vectors $i_2 r_2$ and $i_2 x_2$ are not shown. When the armature current flows through the exciting winding along the axis 53, 54 of the rotor, it produces the motor field M F. Because this motor field closes through iron, it will lag by a small angle γ behind the exciting current as shown in Fig. 62. This field will produce a very large reactance e. m. f. $I x_3$ and the resistance of the field winding will cause the ohmic drop $I r_3$. The e. m. f. e_3 at the terminals of the field circuit must equal and oppose the two last named e. m. fs. and the terminal e. m. f. E must equal the vectorial sum of e_2 and e_3. Because of the unavoidably large reactance of the field circuit, the phase difference between the terminal e. m. f. and the motor current will be large.

As soon as the motor of Fig. 61 revolves at a speed s, the conditions change as indicated in Fig. 63. In this figure, the vector O E represents standstill conditions identical with those of Fig. 62. If the speed

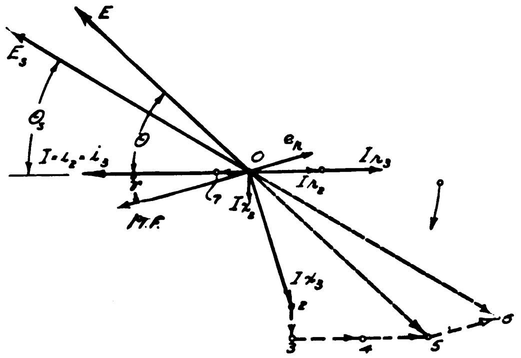

Fig. 63—Phase Diagram of Motor of Fig. 61 When Running

s is secured without any change in the motor current I, then all the vectors of Fig. 62 remain as at standstill, but due to the rotation of the rotor conductors in the motor field, an e. m. f. e_r is generated, the phase of which opposes that of the motor field and causes a reduction in the phase difference between the terminal e. m. f. and the motor current, as is plainly shown in Fig. 63, wherein E_s is the terminal e. m. f. required at the speed s. The greater improvement in the power factor of these motors is, however, brought about by the fact that with increasing speed, the current, and therefore the motor field, diminish, thus causing a diminution of the reactance voltage of the field winding. The effect of the speed e. m. f. e_r, however, immediately indicates how the power factor of such a machine can be increased independently of any change in the motor current. The problem would indeed be solved if it were possible to introduce into the circuit of the motor a speed e. m. f. of a phase substantially opposite to that of the reactance e. m. fs.

In a series conduction motor in which the field winding is located on the stator, no speed e. m. f. other than the back e. m. f. can be produced. When the

field winding, or a part of it, is transferred to the rotor as shown in Fig. 61, then a speed e. m. f. will appear at the brushes 53, 54, being due to the rotation of the rotor conductors in the leakage field along the axis 31, 32 produced by the armature ampere turns and represented by the vector *07* of Fig. 63. For the conditions as illustrated by Fig. 63, this speed e. m. f. would coincide in phase with the flux to which it is due and would, therefore, be coaxial with the vector *07*; it is not shown in the figure. It is evident that this small e. m. f. does not help matters.

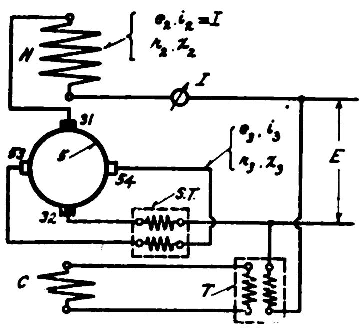

FIG. 64—COMPENSATED AND NEUTRALIZED SERIES MOTOR WITH TWO INDUCTIVELY RELATED CIRCUITS

One way of practically utilizing the suggestion contained in Fig. 63 is shown in Fig. 64. Since the rotor winding along the axis 31, 32 is neutralized by means of the stator winding N, it is clearly possible, without disturbing the conditions within the armature circuit terminals, to produce any kind of auxiliary alternating field in that axis. But if such a field is produced while at least part of the field winding is disposed on the rotor along the axis 53, 54, then a speed e. m. f. will appear along that axis and the phase thereof will be controlled by the phase of the auxiliary alternating field. The magnitude of this speed e. m. f. will depend on the speed of rotation and on the magnitude of the auxiliary field. In Fig. 64, this auxiliary field is produced by means of the stator winding C which is connected to the terminals of the motor, in other words, to the single-phase supply, by means of the shunt transformer T if desired. Under these conditions, the auxiliary field will lag by practically 90 degrees behind the terminal e. m. f. and the speed e. m. f. e_r' will be of same phase as this auxiliary field F'. After the addition of the auxiliary field F' and for an unchanged motor current the phase diagram of Fig. 63 will be transformed into that of Fig. 65, from which it is seen that the compensating speed e. m. f. e_r' is able to bring the terminal voltage and the motor current very near to phase coincidence, notwithstanding the unchanged and large reactance e. m. f. of the exciting circuit. In this diagram, the vector *08* represents the small speed e. m. f. at the brushes 53, 54, due to rotation in the armature leakage field *07*.

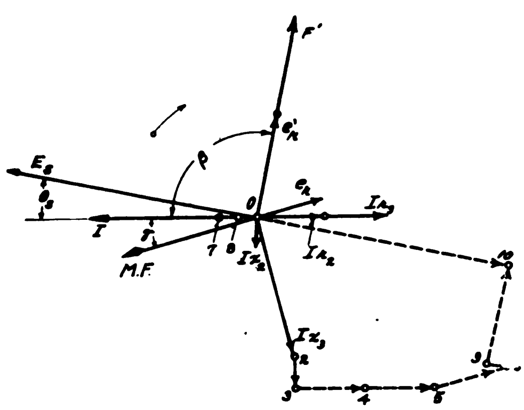

FIG. 65—PHASE DIAGRAM OF THE MOTOR OF FIG. 64 WHEN RUNNING

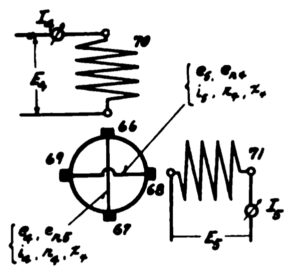

FIG. 66—TWO-PHASE SHUNT INDUCTION COMMUTATOR MOTOR

But the auxiliary flux F' produced by the stator winding C is at right angles in space to the current axis 53, 54 of the rotor, and although the current in that axis does duty as exciting current, it, nevertheless, may react with the auxiliary flux F' and may give rise to a torque. When the phase difference β between the exciting current i_3 and the auxiliary flux F' is 90 degrees, then the torque in question is zero. When β is smaller than 90, this torque is negative and opposes that produced by the interaction of the motor field $M\,F$ and the armature current i_2. When β is larger than 90 degrees, then the auxiliary torque is positive and adds to the power of the motor.

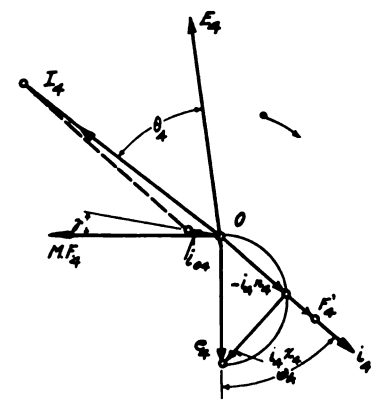

FIG. 67—PHASE DIAGRAM ALONG AXIS 66, 67 OF MOTOR OF FIG. 66 WHEN STANDING STILL

13. Methods of Controlling the Phase Difference in Asynchronous Polyphase Motors

There are polyphase motors with, and without, commutators. The commutator motors are of the induction or conduction type. Such commutator motors of the induction type as have been used in practise all have a shunt characteristic, but some of the conduction machines which have been employed

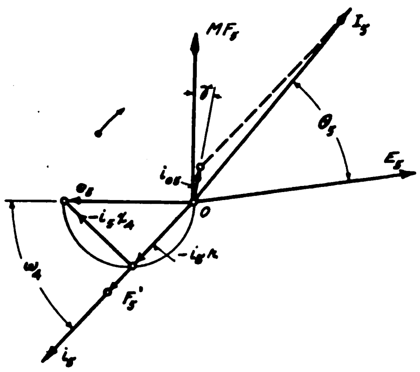

Fig. 68—Phase Diagram Along Axis 68, 69 of Motor of Fig. 66 When Standing Still

have a shunt, while others have a series, characteristic. Commutatorless motors of the induction type all have a shunt characteristic. The inherent characteristic of the polyphase induction type of motor without commutator may, however, be modified to a compound or to a series characteristic by combination with a commutator machine.

In approaching the subject of phase compensation in polyphase motors, reference will first be made to the shunt, induction, commutator motor, the two-phase form of which, is illustrated in Fig. 66.

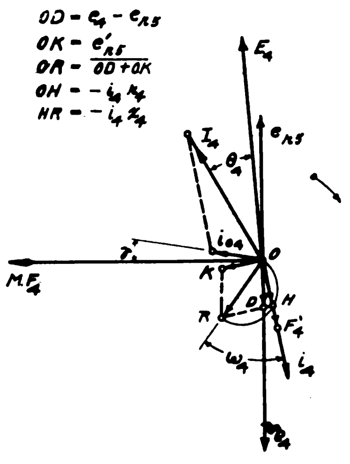

Fig. 69—Phase Diagram Along Axis 66, 67 of Motor of Fig. 66 When Running

With the rotor at rest, this machine behaves just like a short-circuited transformer. The phase diagram for the axis 66, 67 is shown in Fig. 67, that for the axis 68, 69 in Fig. 68. These diagrams are self-explanatory and show that because of the time constant of the rotor, the secondary currents i_4 and i_5, which are the rotor working currents, lag very considerably behind the corresponding rotor working e. m. fs. e_4 and e_5, with the result that the currents in the primaries 70 and 71 also lag considerably behind the respective terminal e. m. fs. E_4 and E_5.

What happens when the rotor is released and allowed to reach its normal and slightly sub-synchronous speed is shown in Figs. 69 and 70 which are the phase diagrams for the axes 66, 67 and 68, 69 respectively. The rotation of the rotor adds two speed e. m. fs. to the active elements in each rotor axis. Thus, in the axis 66, 67 appears the e. m. f. e_{r5}, which is the back e. m. f. in that axis, and is due to rotation of the rotor conductors in the transformer flux produced by the stator 71. The other speed e. m. f. in this axis is e_{5r}' represented by the vector OK of Fig. 69 and due to the rotation of the rotor conductors in the leakage flux set up by the ampere turns due to the rotor current i_5

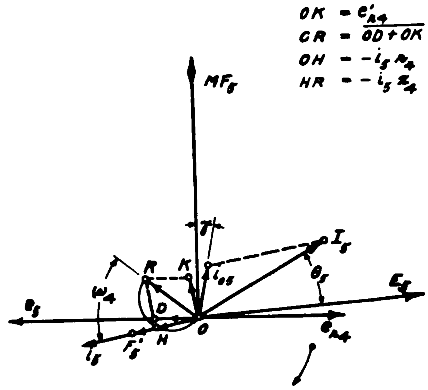

Fig. 70—Phase Diagram Along Axis 68, 69 of Motor of Fig. 66 When Running

circulating along the axis 68, 69. A back e. m. f. e_{r4} generated by rotation in the transformer flux due to the stator phase winding 70 and the additional speed e. m. f. e_{r4}' due to rotation in the rotor leakage flux set up along the axis 66, 67 are added to the rotor circuit 68, 69.

The resultant in each axis between working and back e. m. f. is represented by the vector $O\,D$ which, in combination with the speed e. m. f. $O\,K$, yields the effective e. m. f. $O\,R$ in each rotor axis. Because the time constant of the rotor remains unchanged, the rotor currents must lag behind the effective rotor e. m. fs. by the same angle, regardless of speed, and are shown so lagging in Figs. 69 and 70. Notwithstanding the fact that the time constant of the rotor does not change, it is seen that, when up to speed, the working currents i_4 and i_5 are very nearly in phase with the corresponding working e. m. fs. e_4 and e_5. This is entirely due to the speed e. m. fs. represented by the vectors $O\,K$. One peculiarity of these e. m. fs. is that at synchronism, their magnitude is such as to entirely compensate for the rotor reactance e. m. f. and to

bring the rotor current into exact phase coincidence with the rotor working e. m. fs. These "self-compensating" e. m. fs. vary with the speed. At sub-synchronous speeds, they are smaller than the rotor reactance e. m. fs. At super-synchronous speeds, they exceed the latter.

14. Controlling the Phase Difference in Polyphase Induction Motors with Shunt Characteristic by Introducing into the Armature Circuits e. m. fs. Opposed in Phase to the Rotor Reactance e. m. fs.

a. A study of Fig. 66 and of the four diagrams relating to it at once shows that it is a simple matter to control the phase difference in that machine by amplifying the self-compensating feature of that motor, or in other words, by injecting into the axis 66, 67 an e. m. f. of about same phase as e_{r5}'; and into the axis 68, 69 another e. m. f. of approximately the same phase as that of e_{r4}'. Since the former is about opposite in phase to the terminal e. m. f. E_5 and the latter of about the same phase as the terminal e. m. f. E_4, it is only necessary to provide the arrangement shown in Fig. 71 in order to compensate the motor of Fig. 66 to any desired extent. In Fig. 71, an e. m. f. derived from the stator along the axis 68, 69 is conductively introduced into the rotor circuit at right angles to said axis, while an e. m. f. derived from the stator along the axis 66, 67 is conductively introduced into the rotor axis 68, 69 at right angles to 66, 67.

This method of phase control corresponds to one of the methods described in connection with single-phase motors. In the case of polyphase machines, it is very simple to apply because a polyphase supply is available. It, however, suffers from the disadvantage of increasing the resistance of the working circuits and of adding reactance thereto, thus lowering the efficiency of the motor and making it necessary to inject compensating e. m. fs. of sufficient magnitude to take care of internal, as well as external, reactance. External reactance can, of course, not be taken care of by any self-compensating feature and therefore requires changes in the magnitude of the external compensating e. m. fs., if the power factor is to be kept constant while the load varies. By referring to Figs. 69 and 70, it will be seen that any phase relation within reason can be secured between working e. m. fs. and currents by changing the magnitude of the compensating e. m. f. $O\,K$; and that the rotor working currents can be made to lead to a degree sufficient to compensate for the magnetizing component of the stator windings.

It is not possible to influence the phase relations within a motor of the type shown in Fig. 66 by changing the phase of the exciting e. m. fs. or the phase of the motor fields, and this is for the reason that there is an interdependence and reciprocity between the several axes of such a machine. Thus, the transformer flux produced by the stator winding 70 not only conveys the energy to the rotor or armature along the axis 66, 67, but also does duty as motor field for the currents induced in the rotor axis 68, 69, by the transformer field due to the stator winding 71; which field, in turn, acts as motor field to the currents induced in the rotor along the axis 66, 67. The phase of the rotor working e. m. f. in the axis 66, 67 and the phase of the rotor back e. m. f. in the axis 68, 69, both depend on the phase of the transformer flux set up by the stator winding 70. Similarly, the phase of the working e. m. f. in the rotor axis 68, 69 and the phase of the back e. m. f. in the axis 66, 67 both depend on the phase of the transformer flux produced by the stator winding 71. If the phase of one of the transformer fluxes is changed, the phase relations of working and back e. m. fs. in both axes will be changed, improving the power factor

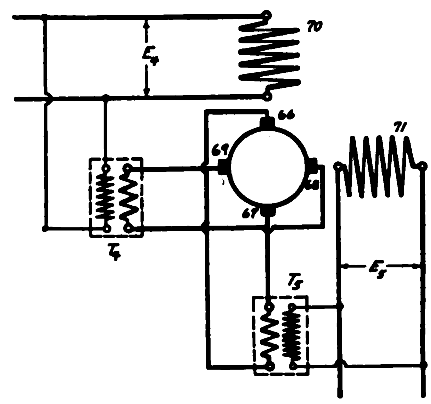

Fig. 71—Compensated Two-Phase Shunt Induction Commutator Motor

in one axis and making it worse in the other. If the phase of both transformer fluxes is altered to the same extent, none of the phase relations within the motor will be changed. Not only does a polyphase induction motor differ from the corresponding single-phase by machine in this matter of reciprocity, but it also differs by the fact that in the single-phase machine, armature and field circuits are both on the induced member; whereas in the polyphase motor, the induced member, generally the rotor, carries nothing but working currents, the motor field being produced by means of the stator or inducing windings.

Polyphase motors of the induction type, but without commutators, can be compensated just as described in connection with Fig. 71, provided care is taken to supply to the induced member e. m. fs. of proper periodicity. In the case of Fig. 71 the brush current periodicity is, at all speeds, the same as that of the stator or of the line, hence the possibility of using the static transformers T_4 and T_5 for deriving the compensating e. m. fs. In the case of a polyphase induction motor with slip rings, the periodicity of the rotor currents as they appear at the slip rings changes with the slip of the machine, being zero at synchronism and increasing proportionately with the slip. The periodicity of the com-

pensating e. m. fs. must vary in the same manner and the phase of each of these e. m. fs. must lead the phase of the corresponding current, or rather that of the corresponding working e. m. f. by about 90 degrees. A number of devices satisfying these conditions were invented soon after it was found that polyphase motors had come to stay and some of these are referred to hereinafter.

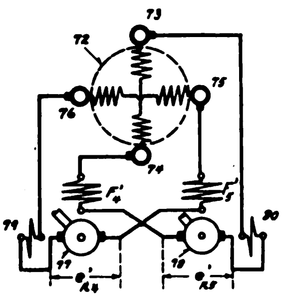

Fig. 72—Polyphase Shunt Induction Slip-Ring Motor With a Plurality of Compensating Series Generators in the Induced Circuit

b. The arrangement shown in Fig. 72 is one of the earliest which were proposed. It is illustrated as applied to a polyphase motor, the induced member 72 of which carries a two-phase winding. Here, as in most of the other cases, a two-phase arrangement has been selected as permitting of clearer illustration. The inducing member is not shown. One of the rotor phases is connected to the slip rings 73, 74 the other to the slip rings 75, 76 and these slip rings are connected to two alternating-current commutator generators driven in any desired manner. Each rotor phase is connected in series with the exciting winding of one generator and the armature of the other. The armature reaction in each generator is neutralized by means of the windings 79 and 80 respectively. The current in the rotor phase 73, 74 produces the exciting flux F_4' of one of the generators. This flux is in phase with the current in the rotor phase 73, 74. By rotation of the generator armature 77 in the flux F_4', an e. m. f. is generated at the brushes of said armature which is always of same phase and same periodicity as the current in 73, 74, and the magnitude of which depends on that of F_4', and on the speed of rotation of the generator armature 77. This e. m. f. e_{r4}' is, therefore, in phase quadrature with the current in the rotor phase 75, 76; and if injected into that rotor circuit in the proper direction, it will oppose the reactance e. m. fs. in that circuit. Similarly, the e. m. f. e_{r5}' generated in the armature 78 by rotation in the flux F_5' of same phase as the current in 75, 76, is in phase quadrature with the current through 73, 74 and is available for compensating purposes in that rotor phase. In fact, the exciting fluxes of the two generators can be compared to the leakage fluxes in the two axes of the rotor of Fig. 66; and the e. m. fs. generated in the armatures 77 and 78 are comparable to the speed e. m. fs. represented by the vectors $O K$ of Figs. 69 and 70, with this difference, that while the speed e. m. fs. in Fig. 66 are of constant frequency, the frequency of the corresponding e. m. fs. in Fig. 72 varies with that of the currents in the rotor of the motor to be compensated and therefore with the slip of said rotor.

Whereas the compensating arrangement of Fig. 71 permits of the power factor to be brought to unity at no load, as well as under any load condition, that illustrated in Fig. 72 does not allow material raising of the power factor at no load, or at light loads, without unduly over-compensating the machine under full-load. The reason for this is that the currents in the rotor 72 vary approximately in proportion with the load, whereas a compensating e. m. f. of nearly constant magnitude is sufficient to ensure a practically constant power factor from no load to full load. The type of compensation shown in Fig. 71 may be termed "shunt" while that shown in Fig. 72 may be spoken of as "series" compensation.

While the sources from which the compensating e. m. fs. are derived in Fig. 72 are not devoid of reactance, yet the arrangement clearly indicates possibilities of materially reducing this reactance as compared with the magnitude of the compensating e. m.fs. which can be generated. Since the periodicity of the compensating e. m. fs. is independent of the speed of the generators 77, 78, these can be operated at high speeds and the exciting fluxes can be kept small, thus reducing the principal source of reactance in these generators. For the same reason, very few armature turns can be used, the desired magnitude of compensating e. m. f. being secured by running the armatures at a correspondingly higher speed. The neutralizing windings 79, 80 further help to reduce the reactance of these compensators.

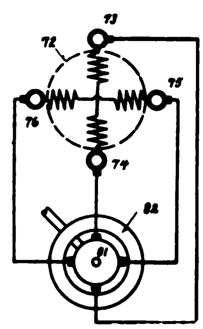

Fig. 73—Polyphase Shunt Induction Slip-Ring Motor With One Compensating Series Generator in the Induced Circuit

c. A simpler and better compensating arrangement for shunt induction motors of the slip-ring type is shown in Fig. 73, where a single compensating generator of the series type is used for all the rotor phases. The stator of the motor to be compensated is not shown; the rotor is again indicated at 72 and is provided with a two-phase winding. One of the phases is connected to the slip rings 73, 74, the other to the slip rings 75,76

The stator of the compensating generator consists of laminations, but carries no winding. The two-pole armature is provided with two sets of brushes displaced by 90 electrical degrees from each other. One phase of the rotor 72 is carried to one set, the other to the other set of these generator brushes. Any suitable provision is made for rotating the generator armature 81 at the desired speed. With the armature 81 at rest and connected to the rotor 72, a revolving field will be produced in the armature and will rotate with the slip frequency of the motor to be compensated. Under these conditions, the armature 81 will exhibit a positive reactance, will, in other words, act like a choke coil. If this armature be now revolved in the direction of the revolving field produced by the rotor currents and at the same speed as this field, then there will be no relative motion between the conductors of the armature 81 and the revolving field and the armature will act as an ohmic resistance. Should the speed of this armature be now increased without changing its direction of rotation, then it will exhibit the properties of a condenser, generating e. m. fs. in advance of the currents circulating through it. These leading e. m. fs. are generated by rotation in the field produced by the rotor currents; their magnitude can

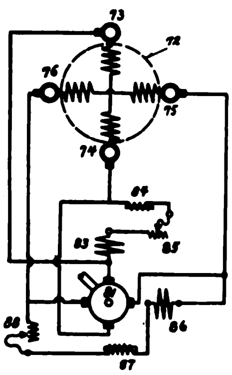

Fig. 74—Polyphase Shunt Induction Slip-Ring Motor With One Compensating Shunt Generator in the Induced Circuit

be raised to any desired degree by raising the speed of the armature 81. Independently of this speed, the periodicity of the leading e. m. fs. will always be the same as the periodicity of the currents circulating through the armature 81. Here, then, is a device with a very small inherent positive reactance capable of generating a compensating e. m. f. greatly in excess of said reactance as to magnitude; for this reason, it is well suited to the service to which it is put.

The stationary laminations 82 can be eliminated, but this would reduce the magnitude of the flux for a given number of ampere turns on the armature 81. It is further possible to combine the stator 82 with the armature 81, partly or entirely eliminating the air gap between the two and cause both of them to revolve in unison.

This device, like the previous one, does not allow of adequate compensation at no-load and the compensation to be secured at light loads is also limited. The power factor can, however, be increased at the light loads without adversely affecting the phase relations under full-load by saturating a part of the magnetic circuit, say for instance, that between the slots in which the winding on the armature 81 is located. In this way, the flux, due to the current circulating in the compensator will not increase in proportion with said current and a greater compensating effect at light loads may automatically be secured without overcompensating at full load. Of course, if complicated regulating arrangements are permitted, then all of these compensators with series characteristic can be made to approach more closely to the performance of compensators with shunt characteristic, but it is not thought that such devices are of practical value. As an indication of their nature, it may be stated that in a device where the laminations 82 are stationary, greater constancy of power factor can be secured by moving the armature 81 out of the stator 82 with increasing load.

d. Series compensating devices fail to produce a high power factor at no-load because of lack of excitation of the compensator when the slip of the motor to be influenced is small. An attempt was made at least partly to overcome this difficulty, and while the writer has no definite data on this subject, he believes that Fig. 74 correctly represents the device in question. It differs from that shown in Fig. 73 in that the stator is provided with two exciting windings 83, 86. One of these exciting windings is located in line with one of the brush sets, the other is coaxial with the second pair of brushes. The winding 83 is connected in parallel with the brushes to which it is coaxial and the same is true of the winding 86. The e. m. f. appearing at each set of brushes co-operating with the armature 81 is, therefore, impressed on the exciting winding coaxial with that set. The object of the arrangement is to produce at each pair of brushes an e. m. f. which will lead the current through that set of brushes by about 90 degrees. Under these conditions and because the flux produced by a shunt exciting winding lags by practically 90 degrees behind the e. m. f. impressed on its terminals, the flux due to the exciting winding 83 will be substantially in phase with the armature current in the vertical axis and therefore substantially in phase quadrature with the current in the horizontal armature axis of the compensator, or vice versa. For this reason, the e. m. f. of rotation appearing at the horizontal set of brushes will be in quadrature with the current through these brushes and the same is true of the vertical set. Because at no-load the slip and the rotor e. m. fs. and currents are small, it is not easy to secure sufficient excitation of the compensator, even with the arrangement of Fig. 72, but acceptable results can be had. The fluxes set up by the currents in the armature

81 induce e. m. fs. in the windings 83 and 86 and rotation of the armature conductors in said fluxes also generates e. m. fs. The former disturb, the latter help compensation and greatly exceed the former if the armature speed is high. Furthermore, the phase relation between terminal e. m. f. and flux varies in the exciting windings 83, 86 with varying slip frequency and this necessitates adjustment of the im-

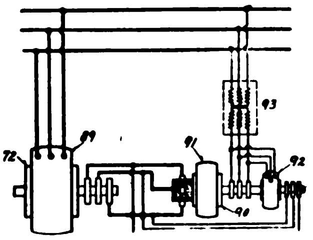

Fig. 75—Polyphase Shunt Induction Slip-Ring Motor With a Compensating Frequency Converter in the Induced Circuit

pedance of these circuits. The easiest way to accomplish this is with the help of adjustable reactances 84, 87 and adjustable resistances 85, 88. The adjustment is so made as to secure e. m. fs., the compensating components of which are nearly constant at all loads. This arrangement is consequently apt to influence the speed, as well as the power factor of the machine. The armature reaction of 81 could be neutralized with advantage.

e. A more perfect method of controlling the phase differences in a polyphase slip ring motor at no-load, as well as at any load, is shown in Fig. 75, where a suitably driven frequency converter is connected between the slip rings of the motor to be regulated and the polyphase line. The frequency converter is nothing but a three-phase synchronous converter provided with a polyphase arrangement of brushes on the commutator instead of the usual direct current brush gear. In the example shown in Fig. 75. the induced member 72 of the motor to be regulated is provided with three slip rings. In consequence, the commutator of the converter 90, 91 is provided with a three-phase arrangement of brushes on its commutator. The slip rings of this converter are connected to the polyphase line by means of the three-phase step-up transformer 93, this being necessary because of the necessarily low voltage of the induced member 72. The stationary member 91 of the converter usually carries nothing but commutating windings.

When the main motor 72, 89 operates near synchronism, the frequency of its rotor currents is very low; it is always proportional to the slip of the rotor. Any compensating e. m. f. introduced into the rotor under these conditions must have the same low frequency and in order to derive this low frequency e. m. f. from the line, the converter 90, 91 is used. When the rotor of such a converter is at rest, then the frequency at the stationary commutator brushes is the same as the frequency at the slip rings. Line frequency being impressed on the slip rings of the converter 91. a revolving flux will be set up in the machine rotating with line frequency and thus accounting for the line frequency voltage at the stationary commutator brushes. The phase relation between any commutator brush voltage and any slip-ring voltage can be varied in the simplest manner by displacing the brushes on the commutator. The voltage between commutator brushes will, however, remain constant for all brush positions. If the rotor 90 of the converter is rotated in a direction opposed to that in which the revolving field produced by the slip-ring currents revolves, then the frequency of the commutator brush voltage will diminish, for the reason that the speed of revolution of the revolving fluxes with respect to the stationary commutator brushes will have diminished. When the speed of the converter reaches the synchronous, the flux produced by the slip-ring currents will be stationary in space, will have no relative motion with respect to the commutator brushes and the e. m. f. at said brushes will be unidirectional. It is thus seen that in order to derive from the converter 90, 91 e. m. fs. of same frequency as the currents in the rotor 72 of the motor to be regulated, it is only necessary to drive the converter in synchronism with the rotor 72. This can be done mechanically by suitably gearing the converter armature 90 to the motor armature 72, or it can be done electrically, for instance, as shown in Fig. 75. Here, a small three-phase motor 92 is arranged to drive the converter. The primary of this auxiliary motor is connected to the line in any desired manner, while the secondary is connected in parallel to the rotor 72. The connections are so made that

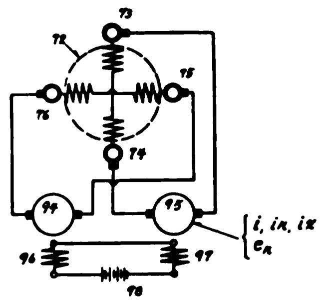

Fig. 76—Polyphase Shunt Induction Slip-Ring Motor With Compensating Oscillators in the Induced Circuit

an increase of frequency in the rotor 72 because of a sub-synchronous speed will cause the auxiliary motor 92 to run at a correspondingly lower speed, while an increase in this rotor frequency, because of a super-synchronous speed of the main rotor 72, will raise the speed of the auxiliary motor by a corresponding amount. The phase of the e. m. fs. derived from the commutator end of the converter can be adjusted by displacing the commutator brushes, or by displacing the stator of the auxiliary motor 92, or by changing the phase of the e. m. fs. impressed on the converter

slip rings. The copper and iron losses of the converter are supplied by the transformer 93, the friction losses by the auxiliary motor 92; and the latter therefore, need only be small. The commutator of the converter must handle the heavy currents of the rotor 72 at a varying, but fortunately, a low frequency, unless this arrangement is also made use of for speed regulation, when the frequencies of the commutator currents will, of course, increase in proportion to the range of speed regulation.

f. Another not so perfect, but very interesting method of controlling the phase difference in a polyphase motor is shown in Fig. 76. It consists in including in each phase of the induced member a direct current armature free to oscillate in a unidirectional

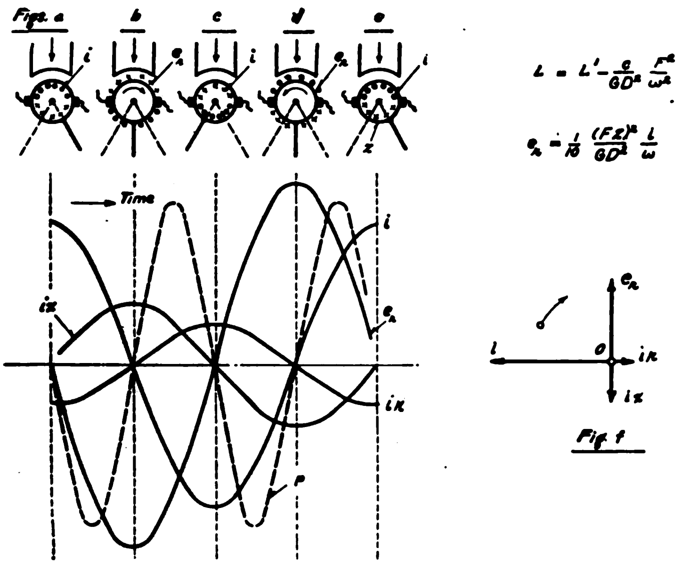

FIG. 77—PHASE RELATIONS IN OPERATING RECUPERATOR, OR VIBRATOR, OR OSCILLATOR

field. These oscillating generators have been referred to as "recuperators" and also as "vibrators." Because of the somewhat unusual type of this apparatus a little space may, advantageously, be devoted to its fuller discussion.

In Fig. 76, the stator of the motor to be controlled is not shown and its rotor 72 is supposed to be provided with a two-phase winding, one of these phases being connected to the slip rings 73, 74, while the other is connected to the slip rings 75, 76. The first phase is closed through the direct-current armature 95, the second through the direct-current armature 94. Each of these armatures is of the usual construction and has a commutator with which cooperate brushes stationary in space. Each of these armatures is so mounted as to reduce friction to a minimum and each is placed in a unidirectional field excited by the field windings 96, 97 connected to a storage battery 98 or to a similar source of unidirectional e. m. f.

The currents in the rotor 72 are alternating, and near synchronism, their frequency is low. The question is, how will an armature such as 94 or 95 behave when an alternating current of low frequency is sent through it by way of the stationary commutator brushes? It will at once be recognized that the armature will be subject to a torque, the direction and magnitude of which, will vary, causing said armature to constantly reverse its direction of rotation. As the armature revolves in the unidirectional field F, see Fig. 77, an alternating e. m. f. e_r will be generated in the conductors of said armature. The amplitude of this e. m. f. will be zero when the speed of the armature is nil, that is, at the moment the armature reverses its direction of rotation; and it will be a maximum when the armature moves at its highest rate of speed, that is, when half-way through its travel. Since an oscillating armature cannot permanently absorb or permanently give out work, it is clear that the e. m. f. e_r must have a phase displacement of 90 degrees with respect to the current i circulating through the oscillating armature, which means that this current will be a maximum whenever the armature is at rest and zero whenever it passes through its intermediate position. For the reasons just stated, and as may be seen from Figs. 77a, 77b, 77c, 77d, and 77e, the e. m. f. e_r will lead the current i and the phase relations will be as shown in Fig. 77 and Fig. 77f. Starting with the armature at rest in the extreme right hand position shown in Fig. 77a, and assuming that the armature current i, which is then at its maximum, flows in a positive direction, this current will decrease as the armature moves in a clockwise direction and will be zero when it is in its intermediate position as shown in Fig. 77b. In Fig. 77a, the speed of the armature is zero, in Fig. 77b, it is a maximum; and the e. m. f. generated by a clockwise rotation of the armature reaches a negative maximum for the position shown in Fig. 77b, declining to zero while the armature goes through the second half of its clockwise motion. The direction of the current reverses when the armature is in the position of Fig. 77b, grows in intensity as the armature goes through the second half of its clockwise motion and reaches a negative maximum when it reaches its extreme left hand position shown in Fig. 77c. The armature now moves in a counterclockwise direction to the position shown in Fig. 77d, during which time, the current diminishes from its negative maximum to zero, while the e. m. f. e_r rises from zero to its positive maximum and so forth. The armature must be accelerated as it goes from the position shown in Fig. 77a, to that of Fig. 77b, and retarded as it moves from the latter to the position shown in Fig. 77c. It must, therefore, absorb work during the first, and give out work during the second, period just named, as indicated by the dotted line P of Fig. 77. Because of the impedance of the armature, there will be an ohmic drop $i\,r$ of opposite phase to i and a reactance e. m. f. $i\,x$ lagging by 90 degrees behind i and it is necessary to so select the constants of the apparatus as to make e_r consider-

ably larger than $i\,x$ if any phase compensation is to be achieved.

If the oscillator is so constructed that it is devoid of elastic reactions and that any damping effects produced are negligible as compared to the moment of inertia $G\,D^2$, then the coefficient of self-induction of the apparatus as a whole can be written in the form of a difference between the coefficient of self-induction of the movable armature winding and a term which is proportional to a constant depending on constructive features of the apparatus, and to the square of the unidirectional flux F and is inversely proportional to the moment of inertia of the armature and the square of the current frequency.

$$\angle = \angle' - \frac{c}{GD^2} \cdot \frac{F^2}{\omega^2}$$

No compensating effect can be produced unless the second member of this equation is made larger than the first. This can be done by making the oscillating element as light as possible and of a very small diameter by using a large unidirectional flux and by reducing the frequency of the current through the armature, thus reducing the angular speed corresponding to the frequency.

Some compensators of this type have been built, and Prof. G. Kapp has given the following formula for e_r

$$e_r = \frac{1}{10} \quad \frac{(F\,Z)^2}{G\,D^2} \quad \frac{i}{\omega}$$

where Z is the number of active conductors on the oscillating armature and ω is the angular speed corresponding to slip frequency. It is interesting to note that because i does not vary with the load as fast as ω, the effect of the compensator is relatively greater at low loads; but this is no drawback, for the reason that the greater compensation is required at the lower load. Nevertheless, it is not possible with this arrangement to secure any appreciable compensation at no-load. Because of the low frequency of the currents circulating through the commutator, and further because at maximum speed of the armature the current is zero, commutation is very good.

15. Controlling the Phase Difference in Polyphase Induction Motors with Shunt Characteristics by Injecting a Unidirectional E. M. F. into the Induced Member

a. In Fig. 78 is shown a three-phase squirrel-cage motor in which the stationary member 109 is the inducing one and is connected to the three-phase supply in the ordinary way. When connected to the supply the stator produces a flux of practically constant magnitude revolving in synchronism with the periodicity of the supply. In normal operation, the squirrel-cage rotor revolves in the same direction as the field produced by the stator and nearly at the same speed as the latter. In order to compensate this machine with the help of a unidirectional e. m. f., and without destroying its asynchronous characteristics, it is only necessary to provide the rotor with an additional, but commuted winding, provide brushes to co-operate with the commutator, rotate these brushes in synchronism with, and in the same direction as, the revolving field produced by the stator and arrange to have the brush axis

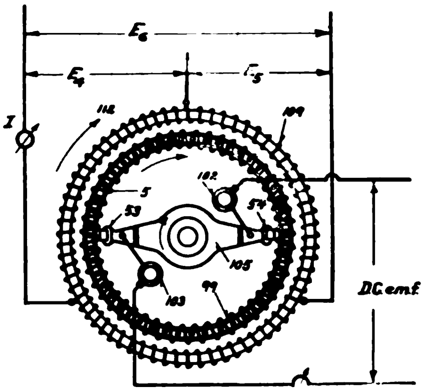

Fig. 78—Polyphase Shunt Induction Squirrel-Cage Motor With Unidirectional Excitation (Stationary Inducing Member)

always coincide with the axis of the revolving field. In this way, it is possible to produce, by means of a unidirectional current sent into the commuted winding of the rotor, a unidirectional flux which will, at every instant, be coaxial with the revolving flux produced by the stator. If the direction and magnitude of the flux

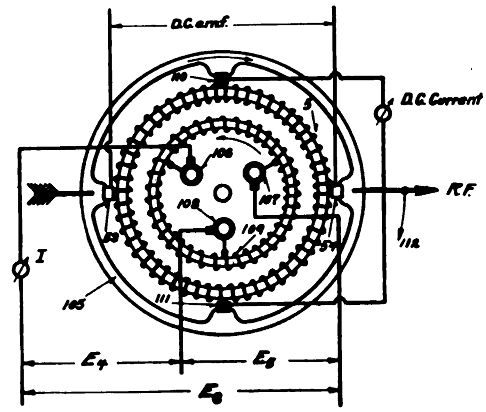

Fig. 79—Polyphase Shunt Induction Motor With Unidirectional Exciting and Load Currents in the Induced Member (Stationary Inducing Member)

produced by the direct current are equal to the direction and magnitude of the flux normally produced by the stator, then all magnetizing currents in the latter will disappear. If the magnitude of the unidirectional flux is increased, then the stator will take leading currents so as to produce a magnetization opposed to the unidirectional one and thus reduce the total magnetization of the motor to that required to balance the terminal e. m. fs. The e. m. f. to be impressed on the compensating brushes can be derived from any desired

unidirectional source. It can, for instance, be taken from the motor itself, as has been explained in connection with Figs. 59 and 60.

If the inducing member of Fig. 78 is caused to revolve while the induced member is held stationary, then the compensating brushes must be revolved at slip speed in a direction opposed to that in which the inducing member rotates.

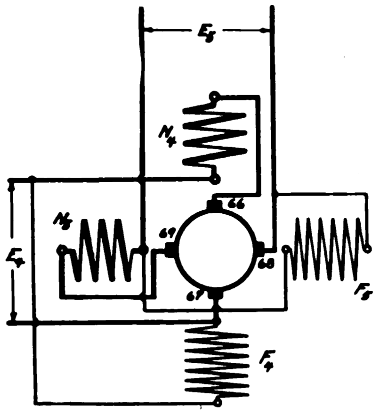

Fig. 80—Neutralized Two-Phase Shunt Conduction Motor

b. There is another type of polyphase induction motor which has not as yet been used in practise, but which is of considerable theoretical interest and also lends itself to the type of phase compensation described in connection with Fig. 78.

This machine is shown in Fig. 79 in the form in which the inducing member is adapted to revolve,

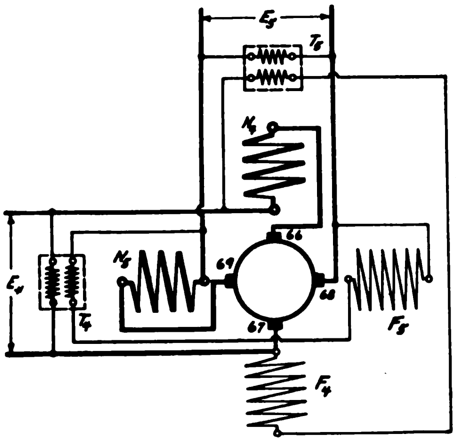

Fig. 81—Neutralized and Compensated Two-Phase Shunt Conduction Motor

while the induced member is stationary. The inducing member is provided with a three-phase winding connected to the slip rings 106, 107, 108 in the ordinary way, while the induced member carries a commuted winding with which cooperate the short-circuited brushes 110, 111. Assume that the slip rings are connected to the supply and that the alternating currents circulating in the inducing member produce a flux $R\ F$ of nearly constant magnitude revolving in a clockwise direction. If the inducing member is now rotated at synchronous speed in a counterclockwise direction, the flux produced by it will become stationary in space and its axis may, for instance, be horizontal as indicated in the figure. Under these conditions, no e. m. fs. will be induced in the windings on the secondary member and if we dispose short-circuited brushes such as 110, 111 along an axis displaced by 90 electrical degrees from the axis of the flux produced by the inducing member, no current will circulate through these brushes and the motor will not be in a position to develop any torque. But if the speed of the inducing member falls below the synchronous, then the axis of the field produced by the inducing member will begin to revolve in a clockwise direction, as indicated by the arrow 112, and at a speed equal to the slip of the inducing member, for the relative speed between the inducing member and the axis of the revolving flux produced by it, must at all times be equal to the synchronous. As soon as the axis of this flux begins to revolve, e. m. fs. are generated in the commuted winding on the induced member and a current flows through the short circuit produced by the brushes 110, 111. If these brushes remain stationary in space, the current circulating through them will have slip frequency, but if they are rotated at slip frequency in a clockwise direction, that is, in synchronism with the flux produced by the inducing member and preferably in such position as to be always at right angles to the axis of said flux, then the short-circuit current will be unidirectional. The short-circuited brushes 110, 111 can be revolved in the desired manner by driving them through a differential gearing, the brushes being driven by the pinion of this gearing, while one of the gear wheels is connected to the shaft of the inducing member and the other to the shaft of a synchronous motor operated from the supply. Such a machine behaves in every respect like an ordinary squirrel-cage polyphase induction motor except that the current in the rotor short-circuit is unidirectional.

In order to compensate this machine, it is only necessary to dispose on the rotor compensating brushes 53, 54 displaced by 90 electrical degrees with respect to the working brushes 110, 111, revolve said brushes in synchronism with the working brushes and impress on them a unidirectional e. m. f. of proper magnitude and direction. Since the working brushes are located and revolve in an axis displaced by 90 electrical degrees with respect to the axis of the revolving field of the machine, the axis of the compensating brush will coincide with the axis of said revolving field, and any flux produced by a unidirectional current entering and leaving the commuted winding on the stator by means of the compensating brushes will affect the magnitude or direction, or the magnitude and direction, of the magnetizing currents circulating in the inducing member and thus modify the power factor of the machine.

In case the inducing member is stationary and the induced member free to revolve, then the system of working and compensating brushes co-operating with the commuted winding on the induced member must be made to revolve at synchronous speed and in the direction in which the induced member revolves.

The unidirectional compensating e. m. f. can be derived from the motor itself by making use of its converter characteristics as has heretofore been set forth with reference to Figs. 59 and 60.

16. CONTROLLING THE PHASE DIFFERENCE IN POLYPHASE CONDUCTION MOTORS WITH SHUNT CHARACTERISTIC BY CHANGING THE PHASE OF THE EXCITING E. M. FS.

The neutralized, polyphase, shunt, conduction motor the two-phase form of which, is shown in Fig. 80, is one which can be compensated by changing the phase of its exciting e. m. fs.

The e. m. f. E_4 of one phase is impressed on the armature circuit comprising the rotor along the axis 66, 67, and the coaxially disposed neutralized winding N_4. This same e. m. f. is impressed on the exciting winding F_4 coaxial with N_4. Similarly, the e. m. f. E_5 of the other phase is impressed on the rotor along the axis 68, 69 in series with the neutralizing winding N_5 and also on the exciting winding F_5 coaxial with N_5. Because the flux due to F_4 lags by about 90 degrees behind E_4 it is of same phase as E_5 or of same phase as the current through the rotor axis 68, 69 when the latter is in phase with its terminal e. m. f. For the same reasons, the flux due to F_5 is in phase with the armature current along the axis 66, 67 when the current is in phase with E_4. In this machine, the motor fluxes F_4 and F_5 are entirely independent of the working circuits and their phase and magnitude can be regulated at will without affecting anything but the torque per ampere and the corresponding back e. m. fs. Consequently, the phase of these back e. m. fs. can be so set as to produce any desired phase relation between the rotor or armature currents and the corresponding terminal e. m. fs., simply by changing the phase of the exciting fluxes. This can be most readily done as shown in Fig. 81. Here, two e. m. fs. are impressed on each of the exciting windings. All of E_4 and such part of E_5 as is determined by the shunt transformer T_5, is impressed on F_4. Similarly, all of E_5 and such part of E_4 as is determined by the shunt transformer T_4, is impressed on F_5. By varying the voltages delivered by the two shunt transformers, it is possible to control the power factor of the motor over an extremely wide range.

Phase compensation produced by modifying the phase of the exciting e. m. f. in single-phase or polyphase motors always yields the best results, and does not require any adjustments in order to obtain a substantially constant power factor from no-load to full-load, or even beyond. The compensating e. m. f. is injected in a highly inductive circuit in which the current is practically constant; and the source of this e. m. f. may be highly inductive without exerting any detrimental effect on the constancy of the power factor.

An attempt has been made to refer to all compensating methods of theoretical interest or of practical value, yet it was not intended to do more than deal with the theories involved and there was no intention to discuss the various applications of these methods. If any method of importance has been omitted, it is due to inadvertence and the author will be glad if his attention is called to it so that this record may be completed.

Most of the compensating methods can, with slight changes, also be used for regulating the speed of alternating-current motors. In fact, the motor speed is often affected by phase control, simply for the reason that a slight change in the phase of the compensating e. m. f. will often bring about a change in speed. Thus, in the case of polyphase induction motors, the e.m. fs. injected into the rotor will do nothing more than compensate the motor as long as they are in phase quadrature with the working e. m. fs. Should this quadrature relation be disturbed, then the speed of the motor will be affected to a degree depending on such disturbance, for it will be remembered that an e. m. f. of the same phase as a working e. m. f. and of the same or opposite direction, will either raise the rotor speed above, or depress it below, the synchronous. When the injected e. m. fs. are not in phase quadrature with the working e. m. f., each is bound to have a speed-changing component.

AIRPLANE RADIO COMMUNICATION

Experiments on the use of radio apparatus as an aid in aerial navigation are described in a publication recently completed. The experiments were conducted jointly by the Post Office Department and the Bureau of Standards and have resulted in the following conclusions:

Radio signaling is a practical aid to navigation provided certain precautions are taken, such as making the radio apparatus sufficiently rigid to stand severe vibration and the use of a special type of antenna located in the fuselage of the machine as far as possible from the engine and the wires of the ignition system. Metal sheaths must be provided to protect the radio receiving apparatus from the ignition system, though the disturbances from this cause can be reduced by the use of a compensating coil in the receiving apparatus.

The use of a coil type of antenna or radio compass makes it possible not only to carry on communication but also to guide the airplane and determine its position by radio methods. By the use of special transmitting apparatus located on the landing field, the airplane is able to determine its position with respect to the field and to descend safely in darkness or fog. Two methods have been found practicable for such signaling apparatus; the use of alternating current of relative low frequency in a large coil on the landing field, and the use of radio signals transmitted from a special type of antenna on the landing field.

AKRON-CLEVELAND MEETING
JANUARY 14, 1921

On Friday, January 14, 1921, the American Institute of Electrical Engineers will hold its 366th meeting under the auspices of the Cleveland and Akron Sections and the Industrial and Domestic Power Sub-committee on the Rubber Industry.

During the morning of the 14th, Institute headquarters will be at the rooms of the Akron Engineering Society, where the Board of Directors and scheduled committees will meet. At 12:30 p. m. luncheon will be served in the cafeteria of the B. F. Goodrich Plant at Akron. An inspection trip through the plant will immediately follow and continue until about 4 p. m. Special cars will leave the plant for Cleveland at about 4:30 p. m. on the Interurban, arriving at about 6:30 p. m.; when a dinner will be served at Hotel Statler ($3.00 per plate). The evening technical session will be held in the rooms of the Cleveland Engineering Society at 8:15 p. m., and will be devoted to the presentation of a paper on "Applications of Electric Power in the Rubber Industry" under the joint authorship of the members of the Subcommittee on Rubber Industry of the Industrial and Domestic Power Committee.

Institute members from the East may obtain through sleepers from New York to Akron, leaving Pennsylvania Station at 6:50 p. m. daily, arriving at Akron at 9:00 a. m. Special cars will leave Cleveland for Akron at 10:00 a. m. from the Interurban Station.

Program

9:30 a. m. Board of Directors
Akron Engineering Society Rooms, 80 South Main Street

9:30 a. m. Scheduled Committee Meetings
a. Akron Engineering Society Rooms, 80 South Main Street
b. Northern Ohio Traction and Light Company Offices, Terminal Building. Akron.
(Hour and place of each meeting will be given in notices to members of committees scheduled to meet.)

12:30 p. m. Cafeteria Luncheon.
B. F. Goodrich Company Plant, South Main Street, Akron.

1:30 p. m. Inspection Trip.
B. F. Goodrich Plant.

6:30 p. m. Dinner (Informal).
Hotel Statler.

8:15 p. m. Technical session.
Cleveland Engineering Society Rooms, 14th Floor, Hotel Statler.
Paper on *Application of Electric Power in the Rubber Industry*, by the Sub-committee on the Rubber Industry.

A. I. E. E. MIDWINTER CONVENTION FEBRUARY 16-18, 1921

The seventh Midwinter Convention of the A. I. E. E. will be held in New York City, February 16-18, in the United Engineering Societies Building.

The Convention will include six technical sessions; visits to various power plants; a dinner dance; and the Edison Medal presentation, followed by a lecture.

Wednesday morning will be devoted to the registration of members and guests in attendance, and making arrangements for visits to the different power plants in New York City and the vicinity, which will be made on Wednesday afternoon. On Wednesday evening there will be a technical session. Thursday morning and Thursday afternoon will also be devoted to technical sessions, and on Thursday evening the usual Midwinter Convention Dinner Dance will be held at the Hotel Astor. There will be technical sessions on Friday morning and Friday afternoon, and the Convention will close with the Friday evening session, at which the Edison Medal will be presented to Dr. M. I. Pupin, as noted elsewhere in this issue. The presentation of the medal will be followed by a lecture, the subject of which will be announced later.

The tentative program is as follows:

PROGRAM

Wednesday Morning, Feb. 16th

Registration Office open.

Wednesday Afternoon

Inspection of local electrical plants.

Wednesday Evening

Opening address by the President.
Results of Questionnaire on Oil Circuit Breakers for the Protective Devices Committee, by H. R. Woodrow.
Tests on Oil Circuit Breakers, by P. Torchio.
Moving pictures and oscillograph records of switches at the instant of failure.

Thursday Morning, Feb. 17th

Sub-committee on Wires and Cables, Standards Committee.
Permissible Operating Temperatures of Impregnated Paper Insulation in which the Dielectric Stress is Low, by W. A. Del Mar, *Chairman*, P. Torchio, D. W. Roper, W. S. Clark, R. W. Atkinson, L. L. Elden.

Thursday Afternoon

Telephone and Telegraph Committee, D. McNicoll, Chairman.
Multiple Use of Wires, by S. Rhoads.
Carrier Wave Telephony, by F. B. Jewett and B. Gherardi.

Thursday Evening

Dinner Dance at the Hotel Astor.

Friday Morning, Feb. 18th

Instruments and Measurements Committee

F. V. Magalhaes, Chairman.

A New Design of Current Transformer, by H. B. Brooks and F. C. Holtz.

Regulation of Frequency for Purposes of Measurements, by P. H. Smith.

A New Type of Differential Voltmeter, by E. D. Doyle.

Variation of Eddy Currents in Conductors of Different Stranding, by J. A. Cooke.

Mechanical Wave Analyser, by F. S. Dellenbaugh.

Stopwatches, by A. L. Ellis.

Friday Afternoon

MISCELLANEOUS SESSION

Short-Circuit Current of Induction Motors and Generators, by R. E. Doherty and E. T. Williamson.

Hysteresis Phenomena with Superimposed Frequencies, by W. Fondiller.

The Longitudinal Flow of Heat in the Windings of Electrical Machinery, by C. J. Fechheimer.

Friday Evening

EDISON MEDAL PRESENTATION

Lecture on Recent Advances in Science.

FUTURE SECTION MEETINGS

Chicago.—January 24, 1921. Subject: "Research, A National Issue and How to Meet it in a Practical Way."

February 28, 1921. Subject: "Dependence of Aerial Transport on Electricity."

Pittsfield.—January 20. 1921. Subject: "On the Frontiers of the Universe, or an Evening with the Stars." Speaker: Mr. B. R. Baumgardt, Lecturer. Los Angeles and New York.

Portland, Ore.—February 7, 1921. Subject: "Public Utility Financing." Speaker: Mr. Geo. Meyers.

Vancouver.—January 17, 1921. Subject: "Electrical Energy Rates." Speaker Mr. E. E. Walker.

NEW YORK SECTION MEETING IN DECEMBER

A joint meeting of the New York Section of the American Institute of Electrical Engineers, the Management and Metropolitan Sections of the American Society of Mechanical Engineers and the Taylor Society was held in the Engineering Societies Building, December 3, 1920.

President Fred J. Miller of the A. S. M. E. presided, and after some introductory remarks presented Mr. Horace B. Drury, recently with the Industrial Relations Division of the U. S. Shipping Board, who presented a paper on "The Three-Shift System in the Steel Industry." The discussion which followed was opened by Robert B. Wolf, Consulting Engineer of New York, and was also participated in by Messrs. William H. Baldwin, formerly secretary of the Ohio Steel Company; S. P. Rectanus, Director of Employment, American Rolling Mill Company; J. A. McCleary, Secretary, Iron and Steel Institute; Harrington Emerson, Consulting Engineer, New York; Whiting Williams, recently Vice-President of the Hydraulic Pressed Steel Company; J. H. Willitts, University of Pennsylvania.

SUPER-POWER SURVEY

In his annual report to the President, the Secretary of the Interior has briefly reported the progress that is being made by William S. Murray and his corps of consultants in the status of the work that has been accomplished to date. It is interesting to note that the Secretary is confident that the report will deserve public confidence. This opinion seems to be borne out in industrial and financial opinions already expressed. The report of the Secretary of the Interior follows:

"Congress at its last session placed upon this department the duty of making a special investigation of the possible economy in fuel, labor, and material that could be secured by electrification of the railroads and industries of the region between Boston and Washington. The plan contemplated is a unified system of power generation and power distribution, and its investigation has been called the super-power survey. This is now under way. The engineering profession and large business interests are giving this project support that is at once an indorsement and a promise of public confidence. The engineering staff engaged in this intensive study of the power needs and the means of meeting that demand includes men who have done pioneer work in applying electricity to the use of man; while serving on an advisory board are men of vision and experience, representing our larger railroads as well as electric railways, our manufacturing and mining industries, and the engineering and chemical profession, busy men who have accepted my invitation to help direct this investigation along lines of greatest practical usefulness. Every industry that has to do with either making power or using power is giving generous cooperation.

"The area being studied, while only a small fraction of the United States—2 per cent—uses 24 per cent of the electric output of the central stations of the country and produces about 47 per cent of its manufactured products. It is properly termed the finishing shop of American industry. The report of this investigation will be completed June 30 next, and its purpose is to give an engineering solution to the problem of the demand of the nation for greater production and better transportation. That answer is electrification, but its details must include the accurate statement of costs in capital and of savings in coal and labor. I believe the report will deserve public confidence."

AMPERE CENTENARY CELEBRATED AT THE CROCKER-WHEELER WORKS

A formal celebration of the electrical discoveries of Ampere was held at the works of the Crocker-Wheeler Company on the afternoon of December 4th. A large number of electrical engineers was present and a special train was provided to take the guests from New York City.

Dr. Schuyler S. Wheeler, President of the Company, acted as Chairman and after some introductory remarks introduced Prince de Béarn, of the French Embassy, of Washington, who gave a brief account of Ampère's accomplishments. Dr. M. I. Pupin was the next speaker and he gave a very interesting story of the intimate details of Ampère's life. The speaking was concluded by Dr. C. O. Mailloux, who represented the French Academy of Science on this occasion, and who read a paper on the subject of fundamental electrical research.

Following the speeches a light luncheon was served, after which the party adjourned to the railway station, where a tablet in honor of Ampère had been erected in 1908. At the celebration last month Prince de Béarn unveiled a bronze wreath with suitable inscription which is to be placed above the tablet in commemoration of this centenary celebration.

EDISON MEDAL AWARDED TO DR. M. I. PUPIN

On December 8, the Edison Medal Committee of the American Institute of Electrical Engineers awarded the Edison Medal for the year 1920 to Dr. M. I. Pupin, "for work in mathematical physics and its application to the electrical transmission of intelligence." Arrangements will be made for the presentation of the medal to Dr. Pupin at a session of the midwinter convention of the Institute in New York on Friday evening, February 18, 1921.

The Edison Medal was founded by the Edison Medal Asso-

ciation, composed of associates and friends of Mr. Thomas A. Edison, and is awarded annually by a committee consisting of twenty-four members of the American Institute of Electrical Engineers "for meritorious achievement in electrical science, electrical engineering, or the electrical arts."

Michael Idvorsky Pupin was born in 1858 in Idvor, Banat, Hungary now forming part of the Kingdom of the Serbs, Croatians and Slovians.

After completing his education at the village school and showing unusual talents he was sent to Prague, Czecho-Slovakia, to continue his education in studies preparatory for higher education. He ran away from Prague and came to America; landed in New York in 1874, and after five years struggle for existence saved up enough money to enter Columbia College, where he graduated with high honors in 1883, with a B. A. degree.

He then went to Europe for the purpose of taking up graduate work in physics and mathematics at the University of Cambridge, England, and at the University of Berlin, Germany and after taking a Ph. D. at Berlin returned to Columbia University where, together with Professor F. B. Crocker, he started in 1889 the Electrical Engineering Department as instructor in mathematical physics. His principal study in Berlin was physical-chemistry, but owing to the fact that physical-chemistry at that time was a new science at the universities in the United States it was not possible to continue his researches in this science at Columbia and he turned his attension to researches in electrical science.

Dr. Pupin's earliest work was devoted to the study of the passage of electricity through rarefied gases and several papers concerning the results were published. In 1892 he took up the subject of electrical resonance, which resulted in the invention of the employment of tuned circuits for selective electrical reception of signals. The expression "electrical tuning" was invented by him at that time and is used in the art today. Also resonance analysis by tuned circuits was worked out by him, employing for means of selectivity by tuning, circuits of variable inductance and variable capacity. The inventions resulting were acquired by the American Marconi Wireless Company in 1902.

In 1895-6 he developed a method of rectifying both low and high frequency oscillations so as to make them detectable by d-c. instruments. The rectifier consisted of a polarized electrolytic cell, and it was clear to him at that time that rectification was a very important element in wireless telegraphy, an opinion which has been wonderfully justified by the developments in the wireless art which have taken place within the last twenty-five years.

The subject of electrical wave transmission over long conductors began to occupy Dr. Pupin's attention as early as 1894, and his earliest work in this direction was chiefly mathematical, and it resulted in an extension of the great problem of La-Grange, namely, the problem of analyzing the motion of a stretched weightless string carrying at equal intervals of its length equal masses. Pupin extended the solution of this problem by supposing that the string itself had weight and that both the string and the masses moved against frictional resistance, taking into consideration not only the free vibrations of the string but also the forced motion produced in it by impressing upon it a simple harmonic force. The solution of this purely dynamical problem suggested immediately its applicability to transmission of electrical waves over telephone wires and it was obvious that the introduction of suitable inductance coils at pre-determined distances along the telephone line would greatly improve the efficiency of transmission by making it possible to transmit the electrical energy carrying the articulate voice of man by high potential and small current, thus reducing ohmic resistance losses on the line. The invention was acquired by the American Tel. & Tel. Co. in January 1901, after this company had convinced itself that the invention was capable of performing those things which the theory had claimed for it. The practical applicability of this invention required the knowledge of making highly efficient inductance coils, using iron cores very finely laminated, and Pupin devoted a study of several years to the investigation of these iron losses, resulting in the design of the toroidal coil, known all over the world as the Pupin coil.

During the war Dr. Pupin served on several national committees connected with war work, particularly the National Advisory Committee for Aeronautics and the National Research Council, and with a Government committee for submarine detection, which had its headquarters at New London. Pupin and his staff were engaged in developing a method of submarine detection by means of very high-frequency sound waves sent out by a panel of vibrating quartz plates. Since the wave length of these sound waves in water was small in comparison with the dimensions of the vibrating plate, the sound waves were concentrated in a beam similar to the light beam sent out by a searchlight. The detection consisted in receiving an echo from a submerged submarine, and it is the only means which enables one to detect submarines which are at rest determining not only the direction but also the distance of the submarine. In prosecuting this work Dr. Pupin developed a multi-step vacuum tube amplifier which is free from internal noises and which does not transmit low frequency under-water noises. This work is now in charge of the United States Navy.

Pupin's work in wireless telegraphy has always occupied his attention, being interrupted now and then by other scientific engagements due to his connection with several national committees. The results of this work were recently acquired by the Westinghouse Company. The principal feature in this work is the so-called negative resistance compensator, which according to competent opinion is destined to play a very important part in the wireless art.

Professor Pupin is a member of the National Academy of Sciences, of the National Research Council, of the Serbian Academy of Sciences, and of many other learned societies, and has been a Fellow of the American Institute of Electrical Engineers for many years. He has received from the French Academy the Herbert Prize in Physics, and from the Franklin Institute the Carson Gold Medal, also the Gold Medal from the Social Science Association. He also holds honorary degree of Doctor of Science, Columbia University, and the honorary degree of Doctor of Laws of Johns Hopkins University. He is now Professor of Electro-Mechanics, Columbia University, and is Director of the Phoenix Research Laboratory of the same university.

ENGINEERS CLUB OF BALTIMORE

The Engineers Club of Baltimore, whose present quarters are at 6 West Eager Street, have made arrangements for new quarters in the Merchants and Manufacturers Building, effective about the first of the year. The new quarters are commodius and will provide, in addition to a lounge and recreation room, an assembly hall with seating capacity of 500, club office. committee rooms for the Club and its affiliated societies and a very comprehensive technical library, on which the Club proposes to spend at least $1,000. per year.

The membership of the Club is being increased rapidly in order to take care of the expansion, and at the meeting of the Campaign Committee, held November 26th, a total of 228 members was reported, or a gain of 100 members in one week, in addition to the societies, which have affiliated with the Engineers Club, aggregating 1000 affiliated members. The affiliation of various other technical societies with the Engineers Club affords such societies facilities of the Club and the use of the assembly hall one night per month. The local sections of the following are now affiliated with the Engineers Club:

American Society of Mechanical Engineers.

American Society of Civil Engineers.
American Institute of Electrical Engineers.
American Association of Engineers.
American Chemical Society

The dues for the Club have purposely been held down as it is desirous to secure as many young members as possible in order to perpetuate the Club and insure a continually increasing sphere of influence.

The dues for full membership are $25.00 per year; Non-resident, $10.00 per year; Associate $25.00 per year; Junior $10.00 per year; Student $5.00 per year.

The advantages offered to members of the Engineers Club are manifold among which are: The opportunity for engineers and technical men to act as a unit; to participate in civic affairs; to meet each other under pleasing surroundings (the centrally located Club Rooms which will be open day and night); access to a technical library and other club facilities and a complete acquaintance in the profession.

The development of Baltimore as a seaport and an industrial center involves a multitude of engineering problems and it is the desire of the Engineers Club to participate to the fullest extent possible in this development.

Application blanks for membership may be obtained from Mr. Wm. F. Strouse, Chief Engineer, Public Service Commission Chairman of Membership Committee; from Geo. S. Robertson 109 East Redwood St., Secretary of the Club, or from any member of the Club.

NOMINATION AND ELECTION OF INSTITUTE OFFICERS FOR 1921-1922

As provided in Section 19 of the Institute By-Laws, candidates may now be proposed for nomination for the offices to be filled at the next annual election in May, 1921, by the petition or by the separate endorsement in writing, of not less than twenty-five members. The petitions or separate endorsements must be in the hands of the Secretary not later than January 25, 1921. For the convenience of members, a form of petition has been prepared by the Secretary, and copies of it may be obtained upon application to Institute headquarters. Endorsements may, however, be made by letter if the form is not available. A member is not limited in the number of candidates he may endorse in this manner.

The officers to be elected are: a President and a Treasurer for the term of one year each, ten Vice-Presidents for the term of two years each, and three Managers for the term of four years each.

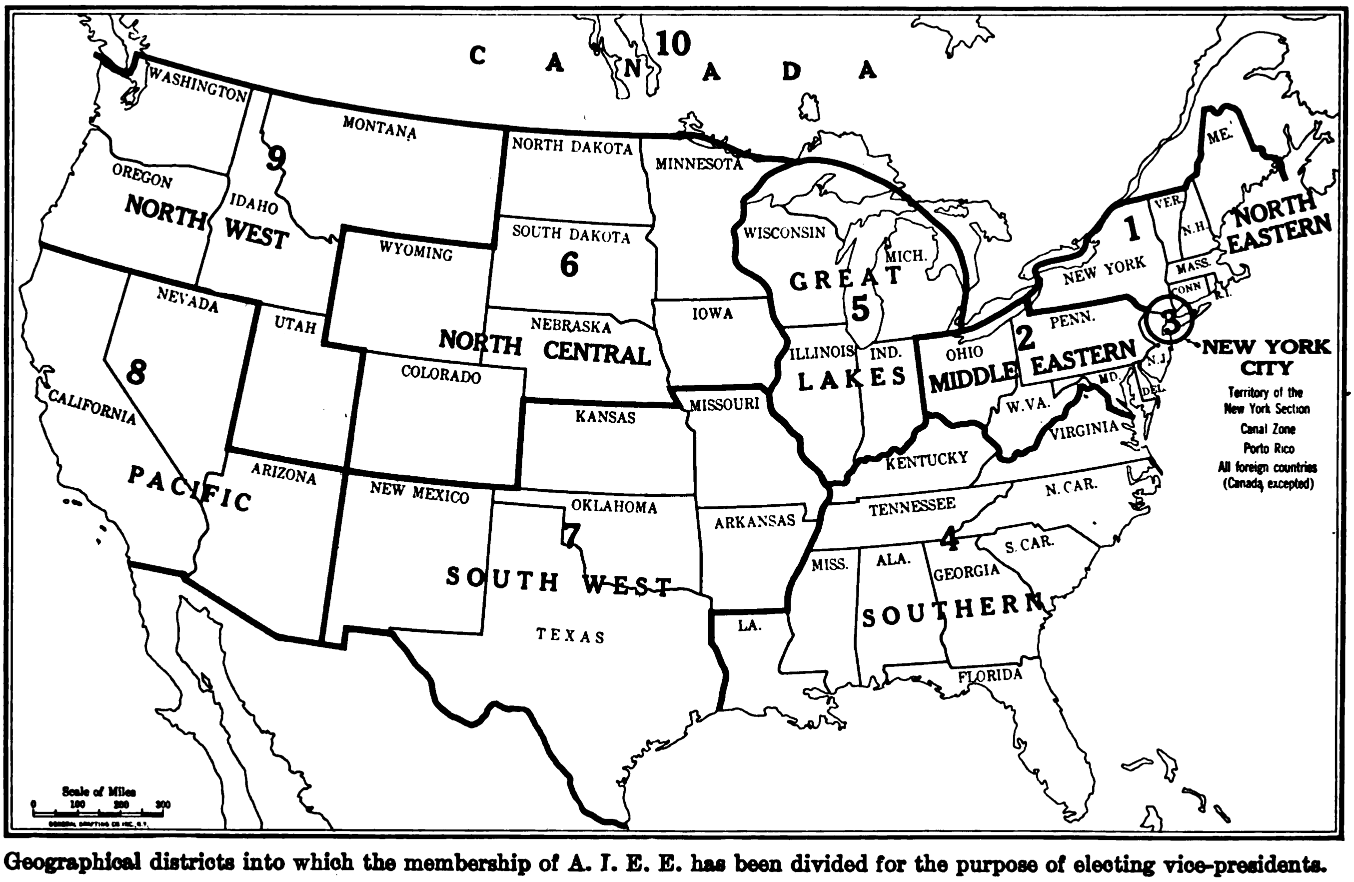
At the Annual Meeting of May 1920, amendments to the Constitution were adopted, carrying out the recommendations of the Committee on Development, in its report of August 12, 1919, that the membership be grouped into geographical districts, that one Vice-President be elected from each district and that Vice-Presidents hold office for a term of two years. The recommendation for the removal of the constitutional inhibition upon the election of a Vice-President as Manager was complied with and the immediate re-election of a Vice-President to the same office provided for with provision against too extended term of office. The former inhibition upon the re-election of a President or Manager to the same office was continued.

At the November 12 meeting of the Directors revisions of the By-Laws were adopted, including the definition of the ten geographical districts decided upon by the Committee on Geographical Divisions and Election Procedure. The ten districts defined in Section 21 of the By-Laws are, as follows:

1. North Eastern: Connecticut (exclusive of N. Y. Section territory), Maine, Massachusetts, New Hampshire, New York (exclusive of N. Y. Section territory), Rhode Island, Vermont.

2. Middle Eastern: Delaware, District of Columbia, Maryland, New Jersey (exclusive of N. Y. Section territory), Ohio, Pennsylvania, West Virginia.

3. New York City: Territory of the New York Section, Canal Zone, Porto Rico, all foreign countries (Canada excepted).



Geographical districts into which the membership of A. I. E. E. has been divided for the purpose of electing vice-presidents.

4. Southern: Alabama, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee, Virginia.

5. Great Lakes: Illinois, Indiana, Michigan, Wisconsin.

6. North Central: Colorado, Iowa, Minnesota, Nebraska, North Dakota, South Dakota, Wyoming.

7. South West: Arkansas, Kansas, Missouri, New Mexico, Oklahoma, Texas.

8. Pacific: Arizona, California, Nevada, Haw'aii, Philippines.

9. North West: Idaho, Montana, Oregon, Utah, Washington, Alaska.

10. Canada:

According to the revised Constitution one Vice-President must be elected from each geographical district but this does not debar members in one district. is they so wish, from nominating and voting for a candidate in another district. When the votes are counted the cadidate for Vice-President having the largest vote in each district will be elected to that particular office for that district, irrespective of the fact that he may have polled a smaller number of votes than a man standing second in another district.

For the information of members the full text of revised sections of the Constitution and By-Laws applying to Officers, nominations, elections, etc.. are printed below:

CONSTITUTION

Sec 23. The officers of the Institute shall be a President, one Vice-President from each geographical district as defined in the By-Laws, twelve Managers, a Secretary and a Treasurer.

Sec. 24. The President, the Secretary and the Treasurer shall hold office for one year, the Vice-Presidents for two years and the Managers for four years. The President and Managers shall not be eligible for immediate re-election to the same office. No Vice-President or Manager who has served continuously in one or more offices, and whose combined terms shall have aggregated six years or more, shall be eligible for immediate election to the office of Manager or Vice-President. At each Annual Meeting the President, the requisite number of Vice-Presidents to fill vacancies caused by expiration of terms, three Managers and the Treasurer shall be elected by the membership, and their terms of office shall commence on the first of August next succeeding their election. . . . . . .

Sec 24 A. At the election of Vice-Presidents held in 1921 there shall be elected one Vice-President from each geographical district, those from the odd-numbered districts to serve for one year each, and those from the even-numbered districts two years each. All Vice-Presidents elected thereafter shall serve for two years each. In the event of a change in the geographical districts, the Vice-Presidents then in office shall complete their terms. In case of revisions of the geographical districts, the Board of Directors shall have the power to elect a Vice-President from each district not represented, to serve until the next election covering these districts.

BY-LAWS

Sec. 19. In addition to the names of the incumbents of office the Secretary shall publish on the "form showing offices to be filled at the ensuing annual election in May provided for in Article VI, of the Constitution, the names, as candidates for nomination, of such members of the Institute as have been proposed for nomination for a particular office by the petition or by the separate endorsement of not less than twenty-five members, received by the Secretary of the Institute in writing by January twenty-fifth of each year: provided, however, that any candidate proposed for nomination by petition may withdraw his name by written communication to the Secretary, and any name so withdrawn prior to the printing of the form shall not be published.

The names of such candidates for nomination shall be grouped alphabetically under the name of the office for which each is proposed, and this by-law shall be reprinted prominently in the December and January issue of each year's Journal and shall be reproduced on the form above referred to.

Sec. 21. There shall be ten geographical districts grouped as follows: (For the balance of this Section describing districts see paragraph preceding map.)

Sec. 21A. Should the territory of any Institute Section lie in more than one geographical district as defined above, then the entire territory of said Section shall be considered as belonging to the geographical district in which the headquarters of the Section are located.

AMERICAN ENGINEERING STANDARDS COMMITTEE

ELECTION OF OFFICERS

At the annual meeting of the American Engineering Standards Committee held in New York on December 4th, Mr. A. A. Stevenson, a representative of the American Society for Testing Materials, was reelected Chairman for 1921, and Mr. George C. Stone, a representative of the American Institute of Mining and Metallurgical Engineers, was reelected Vice-Chairman. The following were also elected to represent the respective member-bodies on the Executive Committee:

Comfort A. Adams	American Institute of Electrical Engineers
Martin Schreiber	American Society of Civil Engineers
Fred E. Rogers	American Society of Mechanical Engineers
A. H. Moore	Electrical Manufacturers Council
Dana Pierce	Fire Protection Group
A. Cressy Morrison	Gas Group
N. A. Carle	National Electric Light Association
Albert W. Whitney	National Safety Council
Coker F. Clarkson	Society of Automotive Engineers
Thos. H. MacDonald	U. S. Department of Agriculture
E. B. Rosa	U. S. Department of Commerce
O. P. Hood	U. S. Department of Interior
Francis J. Cleary	U. S. Navy Department
J. H. Rice	U. S. War Department

A. I. E. E. SPONSOR FOR RATING OF ELECTRICAL MACHINERY

The American Institute of Electrical Engineers was designated as sponsor for the rating of electrical machinery by the American Engineering Standards Committee at its meeting on December 4th, and the responsibility for the work has already been officially accepted by the Institute. A sectional committee is being formed which will contain official representatives of the Electric Power Club, the National Electric Light Association, and the various other interested bodies, to carry out the work.

These arrangements have been made at the request of the electrical industry, in order to prepare as quickly as possible for the next meeting of the Rating Committee of the International Electrotechnical Commission, at which questions of great importance to the industry will be taken up, including the fundamental basis of rating. At the last meeting of the Rating Committee in Brussels in March, 1920, the American delegates presented a proposal for a system of rating based upon the hot-spot principle, which was tentatively adopted by the Rating Committee, and published as a recommendation to the various national bodies composing the Commission for official adoption by the Commission at its next meeting.

TERMINAL MARKINGS FOR ELECTRICAL APPARATUS

The Electric Power Club to act as Sponsor for Standardization

The Electric Power Club has been designated as sponsor for the standardization of terminal markings for electrical apparatus. A sectional committee responsible for the work, and upon which all organizations interested in the subject will be officially represented, is being organized.

At the Brussels meeting of the International Electrotechnical Commission, in March 1920, some of the European delegates proposed a method for marking terminals of transformers. The American delegates suggested that it would be preferable to treat the more general subject of terminal markings for

electrical apparatus consistently. As a result the Americans were requested to propose a systematic plan for the whole subject.

The Electric Power Club has already done a large amount of work on the subject and has developed a general plan which is in wide use among American manufacturers. Parts of the plan, particularly the part relating to transformers, have been adopted by other organizations, including the American Institute of Electrical Engineers and the National Electric Light Association.

It is hoped to secure agreement of all interested bodies, on a general plan for representation at the next meeting of the International Electrotechnical Commission.

NEW BODIES REPRESENTED

The American Engineering Standards Committee has recently been enlarged by the representatives of four additional member-bodies. These bodies and their representatives are:

U. S. Department of Agriculture
- C. L. Alsberg, Chief, Bureau of Chemistry
- Earle H. Clapp, Forest Service
- T. H. MacDonald, Chief, Bureau of Public Roads

U. S. Department of the Interior
- E. A. Holbrook, Assistant Director, Bureau of Mines
- O. P. Hood, Chief Mechanical Engineer, Bureau of Mines
- P. S. Smith, Administrative Geologist, Geological Survey

Gas Group (American Gas Association, Compressed Gas Manufacturers' Association, International Acet lene Association)
- A. H. Hall, Supt. of Distribution, Central Union Gas Co.
- A. C. Morrison, Vice-President, Compressed Gas Manufacturers Association
- H. S. Smith, President, International Acetylene Association

American Electric Railway Association
- (Official representatives not yet designated)

There are now 47 members of the Committee, representing 17 member bodies. In all, 24 organizations are represented on the Committee, as three of the member-bodies are groups of organizations.

STANDARDIZATION OF ZINC

The American Society for Testing Materials and the American Zinc Institute have accepted joint sponsorship for the standardization of zinc under the auspices and rules of procedure of the American Engineering Standards Committee.

The Association Belge de Standardisation has suggested international standardization of the following matters pertaining to zinc: grades of commercial zinc; gage thicknesses and tolerances for sheet zinc; methods of sampling and determining moisture content of ores; and methods of analysis of ore and spelter. The American committee will work along the lines of the Belgian suggestion, but the work will not be confined to these points.

The Belgian Association has suggested similar work on the other non-ferrous metals.

RULES OF PROCEDURE REVISED

As a result of a year's experience, during which progress has been made on each of about 40 standardization projects, the American Engineering Standards Committee has completely re-drafted its Rules of Procedure. Clarification in light of experience was the principal consideration in the revision, and but very few changes in substance, and those minor ones, have been made. The most important of these are explicit recognition of the representation of organizations as such in the make-up of the working ("sectional") committees, and the introduction of a greater flexibility into parts of the rules.

The American Engineering Standards Committee, generally spoken of as the Main Committee, does not concern itself with the technical details of standards. The formulation of any particular standard is in the hands of a working committee, called a *sectional committee*, which is made up of representatives designated or approved by the various bodies, technical, industrial, etc., concerned in the standard. The personnel of the sectional committee must be approved by the Main Committee as being authoritative and adequately representative of the industry, and of the various bodies concerned, producers, consumers, and general interests must be represented upon all sectional committees dealing with standards of a commercial character.

In one important particular the procedure differs from that of other national standardizing bodies. Sectional committees are organized, not by the Main Committee, but by one of the principal bodies interested, designated for the purpose by the Main Committee, and termed the *sponsor* for the particular project. A body may act as sponsor whether it is represented on the Main Committee or not, and two or more bodies may act as joint sponsors for a project.

Copies of the revised rules may be obtained by addressing a request to the American Engineering Standards Committee, 29 West 39th Street, New York City.

ENGINEERING COUNCIL

REGISTRATION OF ARCHITECTS, ENGINEERS, AND LAND SURVEYORS

A recommended uniform law for registration of architects, engineers, and land surveyors was drafted by the Committee on Licensing Engineers, and submitted with the committee's report on December 18, 1919. Council had authorized the creation of this committee on October 25, 1918, and a thorough study of the subject was made during the fourteen months that ensued before the report was completed. Council gave the report wide publicity (See JOURNAL for February, 1920, p. 188) so that others might benefit by the committee's work, and that Council might obtain criticism and experience to aid in further work.

In December, 1919, a Joint Committee of the American Institute of Architects and Engineering Council was created to consider subjects of interest to both architects and engineers. This committee, at a meeting held September 15, 1920, approved the proposition of joint registration laws, and laid down certain basic principles which such laws should contain.

Engineering Council at a meeting held October 21, 1920 adopted the report of the Committee on Licensing Engineers, in which was incorporated a final draft of the recommended uniform law, made to accord with suggestions elicited during the past year. As chairman of this committee, Mr. T. L. Condron said in part, in his letter of transmittal to Engineering Council, October 21, 1920:

I have the honor to transmit to you the attached Report which was prepared and submitted to the sixteen members of the committee on the 4th inst.

At the writer's request Mr. Shenehon, chairman of the Joint Committee and member of License Committee, came to Chicago yesterday, and he and the writer have carefully gone over the entire proposed law so to modify it as to incorporate practically all of the valuable suggestions which have come from the members of our committee and others during the past ten months.

It has also been the aim to make the proposed law satisfactory to the Board of Directors of the American Institute of Architects by incorporating those features recommended by the Joint Committee.

For your information, it is well to state that the License Committee was unanimous a year ago in feeling that the only justification for a law of this kind was as stated in Section 1: "In order to safeguard life, health and property, any person practising architecture, engineering or land surveying shall be required to submit evidence that he or she is qualified so to practise.

* * * * * * * * * * * * * * *

In conclusion, I hand to you the proposed registration law submitted to you nearly one year ago, with some slight modifications and improve-

ments agreed upon between myself and the Chairman of the Joint Committee.

* * * * * * * * * * * * * * * * *

I am sure that I express the sentiments of the majority of the Committee in recommending that Council approve and endorse the attached amended "Recommended Uniform Registration Law for Architects, Engineers and Land Surveyors" as a bill for an act of legislation in each and every State for the regulation of the practise of the professions of Architecture, Engineering and Land Surveying.

Respectfully,
T. L. CONDRON
Chairman License Committee

Francis C. Shenehon of the Joint Committee outlined briefly the purpose of the law in a letter to Engineering Council, November 4, 1920. The main part of his letter follows:

It appears desirable I think to make clear that the final draft of the Registration Law promulgated is a composite representing the views of the original committee on "licensing" and the later committee on "cooperation".

The vital thing in a law of this kind is that it shall furnish the public a reliable criterion by which an architect or engineer may be selected to plan and execute important work. A "registered" architect or engineer has in his title his credentials. A man who offers to practise or does practise, representing himself to be an architect or engineer—because in practise prior to the law—may be embarrased in explaining his status; and men of this kind will register for the prestige of it. This will further discredit those not registering because not qualified. And for persons beginning the practise of architecture or engineering after the passage of this Act, the law rigorously prohibits those not qualified under the law itself from representing themselves, either by the titles "Architect", or "Engineer" in any of its many variations, or in any other way, as architects or engineers.

A carpenter may continue to plan and build sheds, barns, garages, warehouses, dwellings or business blocks, with no implication that he is an architect. A road master may continue to build roads with earth cuts and embankments, culverts and pile or concrete bridges, with no implication that he is an engineer. A contractor may continue to plan and erect cableways, trestles, towers, cement, sheds, dinky railways, or he may plan and erect silos, elevators or office buildings for clients, and with no implication that he is an engineer. A manufacturer may continue to plan and build boilers, engines, water tanks, windmills and turbines without any implication that he is an engineer.

No man can draw precisely the line where the legitimate field of the carpenter, the road master, the contractor, or the manufacturer ends and the field of the architect or the engineer begins. A broad zone of uncertain classification lies between the legitimate fields of these non-professional workers and the field of professional men. Who will exactly define the limits? The courts of course. As a matter of the practical working of a law it is very clear that the courts will rule that structures of any kind that did not as a matter of practise require an architect or a professional engineer prior to the passage of the law, are not placed in the exclusive or monopolistic field of the architect or engineer by the law.

* * * * * * * * * * * * * * * * *

While it might be financially advantageous to architects and engineers to establish a complete monopoly in the design and supervision of all structures, it would not be economically sound from the point of view of the public to require a professional fee of every man who wishes to build a warehouse, a cottage or a trestle. Nor would it be economically sound to require in the allied professions of medicine and law, a professional fee of every man who needed a dose of calomel or a bottle of liniment, or who should draw up a bill of sale, a warranty deed, or a lease. To hope to make of architecture and engineering permanently closed, monopolistic profession when neither medicine or law in the many decades of their licensing limitations have been able to accomplish this, is a dream which architects and engineers would better forget.

Perhaps the man who is to own the garage, the office building or the dam, is best qualified to decide whether he wishes a carpenter, an architect or an engineer to plan it and see to its building—or whether it is important enough to warrant the employment of "registered" men. It is quite certain that the good sense of the owner will secure to him,—with the aid of the discriminating registration law,—the services of competent men.

* * * * * * * * * * * * * * * * *

We may feel sure that a registration law, which plainly separates the certified from the uncertified and prevents misrepresentation, will work to "promote the public welfare, by safeguarding life, health and property."

Very truly yours,
(signed) FRANCIS C. SHENEHON,
Chairman Joint Committee on Cooperation with Architects.

Copies of the recommended uniform law for registration of architects, engineers and land surveyors may be procured by addressing Alfred D. Flinn, Secretary of Engineerng Council, 29 West 39th Street, New York, N. Y.

CURRENT ENGINEERING TOPICS

PATENTS

The Nolan patent bill which passed both Houses of Congress during the last session following hearings at which Engineering Council's patent committee took a prominent part, will go before the Conference Committee immediately after the holiday recess. The Conference Committee which is headed by Senator Morris, who is also chairman of the Senate Patent Committee, will hold hearings to take further testimony in regard to the bill under its present status.

It is contemplated that the old Nolan patent bill with minor changes will become a law during the present session of Congress.

TARIFF HEARINGS

In contemplation of a special session of Congress after the present regular session the House, Ways and Means Committee has announced that it will hold hearings on the various tariff schedules between January 6th and February 16th.

These schedules contain many items affecting engineers' work. Schedule A covers chemicals, oils and paints and will be heard January 6-8. Schedule B covers earth, earthenware and glass and will be heard January 10-11. Schedule C covers metal and metal manufacturing and will be heard January 12-14. The free list will be taken up February 11-14.

FEDERAL POWER COMMISSION

Perhaps the most important item to engineers in the 1921 estimates was a relatively small item calling for a total appropriation of $482,065—the requirements of the Federal Power Commission for the fiscal year 1921. $100,000 it is estimated is required to reimburse executive departments for investigations requested by the Commission. General expense for authorized work of the Commission, exclusive of personnel, is estimated at $137,000 while salaries amount to $240,000. All of these estimates appear to be conservative, in fact, the lowest possible amounts that will permit of effective operation of the Commission under the requirements of the law.

Before these estimates can be acted on for appropriation by Congress under the law, it is necessary to so amend the existing power act as to permit the Commission to spend the money so appropriated. If the law is not amended giving the Commission its additional power, any appropriation bill carrying the items above referred to is subject to a point of order because regular appropriation bills cannot carry new legislation. It was evidently the intent of the original Federal power bill to give the Commission authority to hire and pay its personnel and to expend funds which were appropriated for it, but under a ruling of the controller of the Treasury these funds did not become available.

Engineers' attention is specially directed to the fact that the original bill provided a salary of $5000 for the executive secretary, which position is at present held by a prominent engineer who in private practise would normally be earning three or four times this amount. Some of his assistants are receiving as high as $7500 and a number of their assistants in turn are receiving more than the secretary's salary. This is a big job worthy of the best that the engineering profession can produce, but the salary has got to be corrected and corrected at once.

Since this whole appropriation and especially the question of the secretary's salary will affect practically every phase of the engineering field it is probable that engineers and engineering organizations as such should use their efforts to obtain, first, adequate legislation that will enable the Commission to properly expend this money and second, an appropriation that will permit of proper execution of the law. The need of this legislation and its proper administration is best shown by the fact that 115 applications for permits or licenses for power develop-

ment have been filed with the Commission in less than six months with an aggregate h. p. of over eight million.

It is a well-known fact that after every great war comes some correspondingly great development that offsets or at least tends to offset the losses and wastes of war, and it has been predicted that the water power development will fill that niche in the history that is now being written. The whole program in this country is in the hands of the Federal Power Commission. This is essentially an engineer's project because it affects ultimately practically every phase of engineering. Appropriate legislation will be introduced during the present session of Congress.

TECHNICAL WORK AT THE BUREAU OF STANDARDS

Recent bulletins issued by the Bureau of Standards cover the progress of experimental work that has been started there. The titles of those that are of special interest to engineers are itemized below:

1. Length measurements completed during the month.
2. Recent testing of the ice bar used in the standardization of tapes.
3. Recent weights and measures information.
4. Investigation of methods for measuring focal length of lenses.
5. Completion of a new laboratory telescope.
6. Recent chemical publication.
7. Report on hardeners for concrete floors.
8. Decarburization of steel by heating in vacuo.
9. The preparation of magnesia by a new method.
10. Recent metallurgical publications.
11. Electric resistance of the human body.
12. Airplane radio communication.

Because of the current nature of these investigations, the results are not generally printed, but complete data on all work to date are always obtainable.

THE 1921 ESTIMATES FOR THE BUREAU OF STANDARDS

The 1921 estimates cover the following amounts for work in which engineers are especially interested. The amounts asked this year as compared with the appropriation under which the Bureau is now working are indicated.

1. For apparatus, machinery, appliances, laboratory supplies, furniture for laboratories and cases for apparatus, \$90,000. This is an increase of \$15,000 over the current appropriation.

2. For metallurgical research, including alloy steels; properties of aluminum alloys; development of metal substitutes; investigation of new metallurgical processes, \$70,000. This is an increase of \$45,000 over the current appropriation.

3. For purchase, preparation and distribution of standard materials to be used in checking chemical analysis and in the testing of physical measuring apparatus, \$15,000. This is a new appropriation.

4. For the investigation of the problems involved in the electro-deposition of metals, \$15,000. This is a new appropriation.

5. For testing varnish materials, soap materials, inks, and chemicals \$50,000. This is an increase of \$20,000 over the current appropriation.

6. To develop color standards and methods of manufacture and of color measurement, with special reference to their industrial use in standardization and specification of colorants such as dye stuffs, inks, and pigments, \$12,000. This is an increase of \$2,000 over the current appropriation.

7. To study methods of measurement and technical processes used in the manufacture of pottery, tile and other clay products, \$25,000. This is an increase of \$10,000 over the current appropriation.

8. For the investigation of the problems involved in the production of optical glass, \$40,000. This is an increase of \$15,000 over the current appropriation.

9. To investigate textiles, paper leather and rubber in order to develop standards of quality and methods of measurement, \$40,000. This is an increase of \$25,000 over the current appropriation.

10. High-temperature measurement investigation, \$15,000. This is an increase of \$5,000 over the current appropriation.

11. To determine experimentally important physical contants of materials \$25,000. This is a new appropriation.

12. For the equipment, maintenance, and operation of a low-temperature laboratory and the production of liquefied gases, \$15,000. This is a new appropriation.

13. For an investigation of radio-active substances and the methods of their measurements and testing, \$15,000.

PERSONAL MENTION

W. G. STEARNS, for many years with the Standard Underground Cable Company, on the Pacific Coast, has been appointed Special Sales Agent.

R. L. JESSEE, of the M. B. Austin Company, Chicago, announces that the company has moved into its new building, located at 108-116 S. Desplaines Street, Chicago.

VINTON SMITH has been appointed Assistant Pacific Coast Manager of the Standard Underground Cable Company. He has been with the San Francisco office staff for several years,

W. G. SCHMAUDER has been appointed assistant general manager of the Texas Light & Power Company, Dallas, Texas. His duties will be of a general nature in looking after the various phases of the business.

GRENVILLE A. HARRIS has resigned his position as chief engineer of the American Steel Export Company, and has opened up an office of his own, Room 2914, Woolworth Building, New York, where he will operate as an export engineer, acting as consulting or advisory engineer on export to various manufacturers of this country.

E. J. WHITE and M. C. WRIGHT have severed their connections with the K. W. Electric Company, and have organized the Harris-Wright Company, Inc., to specialize on electric motor sales, repairs and maintenance and the engineering in connection with the application and installation of the above apparatus. The officers are located at 30-32 Liberty Street, Newark, N. J.

A. W. K. BILLINGS, of Barcelona, Spain, is in the States on a brief visit, his mail address being in care of the Engineers Club, New York City. Since 1912 he has been on the extensive hydroelectric and other work of the Ebro Company, filling the positions successively of manager of construction, managing director, vice president, and consulting engineer. During the war he was in charge of Naval Aviation construction in Europe, and was promoted to the rank of Commander and awarded the Legion of Honor and the Navy Cross for distinguished service in this work.

JAMES R. CRAVATH, owing to the ill health of one of his family, finds it advisable to move his residence to California, and therefore the firm of Fowle & Cravath has discontinued business. FRANK F. FOWLE announces that the new firm of Frank F. Fowle & Co. will continue the business at the same address, covering the field of electrical and mechanical engineering as heretofore. The advisory services of Mr. Cravath in

illuminating engineering matters will still be available, as he will retain a connection with the new firm for that purpose.

W. L. R. Emmet was awarded the Elliott Cresson Gold Medal by the Franklin Institute of the State of Pennsylvania, acting through its Committee on Science and the Arts at its meeting November 17, 1920.

The wording of the award was as follows:

"After a careful consideration and study of Dr. Emmet's work relating to ship propulsion, the Institute is of the opinion that it deserves the highest award in its gift for the recognition of inventions of signal importance and awards to Dr. W. L. R. Emmet the Elliott Cresson Medal in recognition of his 'Notable Contributions to the Art of Ship Propulsion."

Richard G. Harris of the Standard Underground Cable Company succeeds as Pacific Coast Manager, Mr. John P. Bell, who will hereafter devote his time to the growing demands of his export and import business. Mr. Harris has been connected with the Standard organization since 1909 when he was a member of the staff of the general offices of the Company at Pittsburgh, and on special development matters at its Perth Amboy, New Jersey, factories, and later Sales Engineer with the New York office of the Company. For the past eight years he has been Manager of the Montreal office territory of the Standard Underground Cable Company of Canada, Ltd.

Ethan Viall, for ten years on the staff of the *American Machinist*, has resigned as editor-in-chief to become a member of the firm of T. W. Minton & Company, Barbourville, Ky., large producers of hickory dimension stock. Previous to joining the staff of the *American Machinist* Mr. Viall was for three years associate editor of *Machinery*, and before that he was for fourteen years foreman and superintendent in several of the largest specialty plants in the middle west. He is the author of "Electric Welding," "Gas Torch and Thermit Welding," "Broaches and Broaching," "United States Artillery Ammunition," "United States Rifle and Machine Guns," and "Manufacture of Artillery Ammunition." He is a Member of the Institute, of the American Society of Mechanical Engineers, and of the Society of Automotive Engineers.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK WANTED BY LIBRARY

The Engineering Societies Library desires to obtain one or two copies of the Manual du Repertoire Bibliographique Universal. Brussels: Institut International de Bibliographie. Any one having a copy for sale or knowing where one can be found, will please communicate with the Director of the Library, 29 West 39th St., New York.

BOOK NOTICES (FROM NOV. 1-30, 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

Applied Naval Architecture.

By W. J. Lovett. Lond. and N. Y., Longmans, Green & Co., 1920. 10 + 654 pp., charts, tables, diagrams, 9 x 6 in., cloth. $12.00.

Contents: Bilging—Board of Trade Requirements—Designing—Freeboard—Hydrostatic Curves and Captain's Information—Launching—Resistance and Horse Power—Rudders and Steering—Stability and Trim—Strength—Tonnage. Laws and Measurements—Weights, Stowages and Tables.

The present work is a specialized treatise on the design and construction of moderate-speed merchant vessels, 350 ft. and upwards in length. As naval architecture is not an exact science, absolutely accurate solutions are not necessary in many cases, and for these the author has given special attention to approximate methods, whereby results may be obtained rapidly.

A Builder of the New South; being the Story of the Life Work of Daniel Augustus Tompkins.

By George Taylor Winston. Garden City, N. Y., Doubleday, Page & Co., 1920. 8 + 403 pp., port., 8 x 6 in., cloth, $3.00.

The subject of this biography was born in South Carolina, in 1851. Educated at the University of South Carolina and Rensselaer Polytechnic Institute, he first became an assistant to Alexander L. Holley, and later an employee of the Bethlehem Iron Works, under John Fritz. In 1882, he established himself in Charlotte, N. C., and from that time, until his death in 1914, was active in the development of the industries of the South and the promotion of technical education. Because of his wide interests, the story of his life is, in no small measure, the story of the industrial reconstruction of the South.

Calcul des Organes des Machines.

By J. Boulvin. Paris, Gauthier-Villars et Cie, 1921. 9 + 515 pp., diagrams, charts, 10 x 7 in., paper.

The present work deals with the calculation of boilers, cylinders, pipe systems, rotating and reciprocating machinery, eccentrics, gearing and transmission systems. Throughout, it is concerned with the determination of their dimensions from the resistance of materials, so that the tension or deformation will not exceed the limits desired. Empirical formulas are avoided. Numerous difficult problems have been given special attention and are treated in a novel manner.

Chemical Reactions; Their Theory and Mechanism.

By K. George Falk. N. Y., D. Van Nostrand Company, 1920. 7 + 211 pp., 8 x 6 in., cloth, $2.50.

The central idea of this book is the development of a general theory of reactions which will include both inorganic and organic reactions. The theory set forth is based upon the "addition" theory that, when two or more substances react, a

primary addition is the first step. Although the addition theory has been used to explain isolated reactions, the author believes this to be the first attempt to apply it generally.

THE COLUMBIA BASIN IRRIGATION PROJECT, A REPORT OF COLUMBIA BASIN SURVEY COMMISSION.

Olympia, 1920. 185 pp., illus., maps, tables, diagrams, 9 + 6 in., cloth.

This report discusses the engineering, economic and financial aspects of a plan proposed for the irrigation of 1,753,000 acres of land in southeastern Washington, using water supplied by gravity.

THE CONSTRUCTION OF ROADS AND PAVEMENTS.

By T. R. Agg. Second edition, revised and enlarged. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 10 + 463 pp., illus., charts, diagrams, tables, 9 x 6 in., cloth, $4.00.

The present book was written to meet the need for a concise presentation of approved practise and of the principles involved. It is intended primarily for use as a textbook, but includes tables, typical designs and specifications valuable to highway engineers for reference use.

In this edition, the errors and omissions of the first have been corrected. New material has been added on assessments for pavements, on drainage, the control of erosion, maintenance, proportioning aggregates and on the testing of materials.

DICTIONARY OF EXPLOSIVES.

By Arthur Marshall. Phila., P. Blakiston's Son & Co., 1920. 14 + 159 pp., 9 x 6 in., cloth, $3.75.

It is a generation since a dictionary of explosives has been published, and in the meantime many new explosives have been introduced. It is therefore hoped that this small volume, giving concise information about them, may prove useful. The book is restricted to explosives with special or proprietary names, in order to keep it of moderate size. It gives brief data on the composition, use and source of the explosives mentioned.

ELECTRIC TRACTION AND TRANSMISSION ENGINEERING.

By Samuel Sheldon and Erich Hausmann. Second edition, revised. N. Y., D. Van Nostrand Co.; Lond., Crosby Lockwood & Son, 1920. 12 + 307 pp., illus., diagrams, charts, 8 x 5 in., cloth, $3.00.

This text-book attempts to present a prospective view of the design of a complete railway installation, from the cars to the power station, to indicate the nature and sequence of the various problems entailed, and to suggest or illustrate methods for their solution. It is intended to assist students and young engineers to discriminate as to the pertinency or necessity of specific details.

THE FIREMAN'S HANDBOOK AND GUIDE TO FUEL ECONOMY.

By Charles F. Wade. Lond. and N. Y., Longmans, Green & Co., 1920. 84 pp., diagrams, 7 x 5 in., boards. $1.00.

This little handbook explains clearly and concisely the correct way to fire and operate boiler and other furnace plants, and the reasons why the methods suggested are correct. The language is simple and can be understood by men with little ability to read.

HANDBOOK OF ENGINEERING MATHEMATICS.

By Walter E. Wynne and William Spraragen. Second edition, revised and enlarged. N. Y., D. Van Nostrand Co., 1920. 8 + 282 pp., diagrams, charts and tables, 7 x 4 in., cloth.

This is an endeavor to present in handy form and convenient pocket size, references to the theoretical and applied mathematics used in engineering. It contains the underlying engineering data and applications, as well as the mathematical formulas.

The present edition has been enlarged by additions to the mathematical sections and tables of functions, and the physical and chemical constants have been revised.

THE HANDBOOK OF INDUSTRIAL OIL ENGINEERING.

By John Rome Battle. Vol. 1. Lubrication and Industrial Oil Section. Phila. and Lond., J. B. Lippincott Co., cop. 1920. 8 + 1131 pp., illus., diagrams, tables, charts, 8 x 5 in., cloth. $10.00.

This handbook is intended to assist in the intelligent selection and use of lubricants for all purposes, and has been prepared for manufacturers, sellers and users of industrial oils. The range covered is a wide one and includes the use of oils in heat treating steel, in foundry practise, in soap making and as insecticides, as well as for lubrication. Specific information on the use of oils in the major industries is given. The book also has a section on marketing and a selection of mathematical and engineering data.

INDUSTRIAL STABILITY.

Edited by Carl Kelsey. (Vol. 90 of the Annals of the American Academy of Political and Social Science) Phila., 1920. 4 + 164 pp., 10 x 7 in., paper, $1.00

The thirty-four papers here brought together as contributions to current discussion of the general subject, present the views of business men, manufacturers, philosophers, social workers, attorneys and economists on one of the most pressing questions of the day. The major topics are the trend toward industrial democracy, labor representation in industrial management, collective bargaining, securing production, and industrial stability; and the individual papers are grouped accordingly.

LABORATORY MANUAL OF TESTING MATERIALS.

By William Kendrick Hatt and H. H. Scofield. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 10 + 178 pp., tables, chart and diagrams, 8 x 5 in., cloth, $1.25.

This concise manual of instructions for procedure in the usual physical tests of structural materials is the outcome of the operation of the Laboratory for Testing Materials of Purdue University. It is intended as a guide in class work and investigations and to explain the details of the methods.

The present edition has been thoroughly revised in accordance with current practise.

LESSONS IN MECHANICS.

By William S. Franklin and Barry MacNutt. Bethlehem, Pa., Franklin and Charles; Lond., Constable & Co., Ltd., 1919. 11 + 221 pp., diagrams, 9 x 6 in., cloth, $2.00.

LESSONS IN ELECTRICITY AND MAGNETISM.

By William S. Franklin and Barry MacNutt. Bethlehem, Pa., Franklin and Charles; Lond., Constable & Co., Ltd., 1919 (reprinted 1920). 16 + 254 pp., illus., diagrams, 9 x 6 in., cloth, $2.25.

LESSONS IN HEAT.

By William S. Franklin and Barry MacNutt. Bethlehem, Pa., Franklin and Charles; Lond., Constable and Co., Ltd., 1920. 11 + 147 pp., diagrams, charts, 9 x 6 in., cloth, $2.00.

These three volumes are intended to meet the needs of the two-year schedule in elementary physics which has recently been adopted in some technical schools, and in accordance with the opinion of the authors that most of the added emphasis involved in this schedule should be directed toward the mathematical basis of the subjects. The central idea of these texts is that mathematical training must be accomplished by the combined efforts of teachers of mathematics and teachers of physics, and the books are designed to help the latter to fulfill his proper function in this respect.

THE MANUFACTURE OF SUGAR FROM THE CANE AND FROM THE BEET.

By T. H. P. Heriot. Lond. and N. Y., Longmans, Green and Co., 1920. (Monographs on industrial chemistry). 10 + 426 pp., plates, diagrams, tables, 9 x 6 in., cloth, $8.50.

This is a systematic description of the manufacture of sugar, covering all the operations and elucidating the principles that underly them. Detailed descriptions of sugar machinery are omitted, as the book is intended to give a broad, but accurate view of the whole industry, rather than to cover the technical details of manufacture.

THE MINING CATALOG FOR THE YEAR 1920.

Compiled and Published Annually by the Keystone Consolidated Publishing Company, Pittsburgh. 1363 pp., illus., 12 x 9 in., cloth.

The editors of this volume have endeavored to produce a work of practical use to coal mine managers, purchasing agents and engineers. The book is divided into sections, each treating of a broad subject. Each division opens with a selection of technical information upon the subject, followed by descriptions of machinery used for the purpose, which have been prepared by the manufacturers and are condensed catalogs of their products. The volume is completed by good indexes of the firms and products represented.

MUNICIPAL LANDING FIELDS AND AIR PORTS.

Compiled and edited by George Seay Wheat. N. Y. and Lond., G. P. Putnam's Sons, 1920. 14 + 96 pp., map, plates, diagrams, 8 x 5 in., cloth.

The need for flying routes and landing fields is the most acute and immediate problem facing commercial aeronautics. Until these are provided, little progress toward the solution of other questions is possible. The present book is intended to present to the public the entire problem involved in creating and administering flying routes, landing fields and airports.

EIN NEUES PRINZIP FÜR DAMPF UND GASTURBINEN.

By Konrad Baetz. Leipzig, Otto Spamer, 1920. 80 pp., illus., diagrams, 10 x 6 in., paper.

The author states that the investigations described in this monograph have occupied his attention for twenty years, but that his inability to construct a model machine has caused him to publish his record of his work, in the hope that further investigations may be stimulated thereby.

The problem under consideration is that of combining, in a single machine, the modes of action of the reciprocating steam engine and the steam turbine. This the writer accomplishes by a "cellular" turbine, whose rotating member is composed of cells, in which the steam alternately is compressed and expanded. The book gives the theoretical calculations supporting the author's theory and the results obtained by experiment.

NOTES ON MAGNETISM.

By C. G. Lamb. Cambridge, The University Press, 1920. 8 + 94 pp., diagrams, 9 x 6 in., paper, $2.00.

These notes, drawn up for the use of students in the Engineering Laboratory, Cambridge University, contain an outline of such portions of magnetic theory as are required in order to read the ordinary technical textbooks with intelligence.

THE OIL SHALE INDUSTRY.

By Victor Clifton Alderson. N. Y., Frederick A. Stokes Co., 1920. 11 + 175 pp., illus., 9 x 6 in., cloth, $4.00.

CONTENTS: The Dawn of a New Industry—Nature, Origin and Distribution of Oil Shale—The History of Oil Shale—Mining Oil Shale—Retorting and Reduction—Experimental and Research Work—Economic Factors—Summary—Opinions—The Future—Bibliography.

Dr. Alderson's book is put forth as a general description of the industry, its history and its future, intended for the investor and business man, as well as for the engineer. As the industry is still in an experimental stage, he has not tried to describe any special processes in detail, but has confined himself to the discussion of the general scientific principles which must be followed, and to accounts of the experimental work now being done.

DIE PHYSIKALISCHEN UND CHEMISCHEN GRUNDLAGEN DES EISENHÜTTENWESENS.

By Walter Mathesius. Leipzig, O. Spamer, 1916. 16 + 439 pp., plate, tables, charts and diagrams, 10 x 7 in., cloth. (Purchase.)

In order that the reader's attention may be concentrated upon the physical and chemical principles involved in the metallurgy of iron, descriptions of the mechanical equipment and apparatus have been omitted, except when necessary to elucidate these principles. The book discusses in detail the physical and chemical laws and hypotheses, the fuels, the production of pig iron, wrought iron and steel, and the casting of iron and steel.

POWDERED COAL AS A FUEL.

By C. F. Herington. Second edition, revised and enlarged. N. Y., D. Van Nostrand Co., 1920. 12 + 338 pp., front., illus., diagrams, tables, 9 x 6 in., cloth, $4.50.

In the two years that have elapsed since the first appearance of this work, the use of powdered coal has been greatly extended, and the book is therefore reissued in order to present the economies that have been effected and the various uses to which powdered coal has been applied.

The processes for powdering coal, the suitable coals and the methods of using it are described in the introductory chapters. The remainder of the book gives the results obtained in various industries. A twenty page bibliography is included.

POWER WAGON REFERENCE BOOK, 1920.

Edited by Stanley L. Phillips. Chic., The Power Wagon Publishing Co., 880 pp., illus., tables, diagrams, 21 x 9 in., cloth.

This volume is a combination buyers' directory, encyclopedia and engineering handbook of motor trucks. The first section, on motor trucks, comprises lists of makers of trucks and truck parts, both gas and electric, tables of specifications, blueprints and articles on the use of trucks in various industries. Trailers, bodies and tractors are given similar treatment in succeeding sections, and these are followed by a collection of articles of a general nature. The book ends with a classified buyers' directory.

THE PRACTICAL DESIGN OF PLATE GIRDER BRIDGES.

By Harold Hughes Bird. Lond., Charles Giffin & Co., Ltd.; Phila., J. B. Lippincott Co., 1920. 8 + 180 pp., diagrams, 9 x 6 in., cloth.

This work, of English origin, has been written for young engineers and draftsmen engaged on the design of structural steelwork. It is particularly for those whose training has been more on the theoretical than the practical side and is intended to bridge the gulf between a knowledge of the principles of design and the actual application of that knowledge to the design of plate girder bridges and structural steelwork generally.

PRACTICAL RIVER AND CANAL ENGINEERING.

By R. C. Royal Minikin. Lond., Charles Griffin & Co., Ltd.; Phila., J. B. Lippincott Co., 1920. 7+123 pp., illus., diagrams, 9 x 6 in., cloth.

The author of this treatise is Chief Civil Engineer to the Brazilian Government Development Commission. His book is an endeavor to explain the principles underlying the successful treatment of inland waterways, and then to state concisely and clearly well-ascertained facts free from those data, such as dimensions and costs, that vary greatly with circumstances. The emphasis is therefore upon root principles rather than historic and economic details, and the author has drawn upon wide practical experience.

PROCEEDINGS, ANNUAL CONVENTION, INDUSTRIAL RELATIONS ASSOCIATION OF AMERICA, Chicago, 1920.

592 pp., 9 x 6 in., paper, $5.00.

The papers presented at this conference, held in May, 1920, are divided into two groups, one consisting of general problems, the other of those peculiar to specific industries. The collection covers a wide range of topics connected with the relations of workmen and employers.

PUMPING BY COMPRESSED AIR.

By Edmund M. Ivens. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1920. 6 + 266 pp., illus., tables, charts, diagrams, 9 x 6 in., cloth, $4.00.

The intent of the book is to provide the student with a comprehensive theoretical study of the subject and the operating engineer with information on the economic essentials of the actual installation. The present edition has been enlarged by thirty pages of reliable operative data.

RELATIVITY; THE SPECIAL AND THE GENERAL THEORY.

By Albert Einstein. Translated by R. W. Lawson. N. Y., Henry Holt & Co., 1920. 13 + 168 pp., port., 9 x 6 in., cloth, $3.00.

Dr. Einstein has attempted, as far as possible, to give an exact insight into the theory of relativity to those readers who are interested in it, from a general scientific and philosophical viewpoint, but who are not conversant with the mathematical apparatus of theoretical physics. The book assumes more than an elementary education and, despite the shortness of the book, a fair amount of patience and force of will, will be necessary to comprehend it. The author, however, has spared no pains in the endeavor to present the main ideas in the simplest and most intelligible form.

SPACE AND TIME IN CONTEMPORARY PHYSICS; AN INTRODUCTION TO THE THEORY OF RELATIVITY AND GRAVITATION.

By Moritz Schlick. Rendered into English by Henry L. Brose. N. Y., Oxford University Press, American Branch, 1920. 10 + 89 pp., 9 x 6 in., cloth, $2.50.

The theory of relativity consists of two parts, the old special theory, and the more recent general theory. This book is intended as an introduction to the whole set of ideas contained in this theory and should interest especially those who are concerned with the general conceptions rather than the details. Its essential purpose is to describe these physical doctrines with particular reference to their philosophic significance. The present edition varies from the previous one only in minor improvements.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Baltimore.—November 19, 1920, Johns Hopkins University. Subject: "The Transmission of Speech and Music Through the Mediums of the Piezo-Electric Effect in Crystals." Speaker: Alex. McF. Nicholson, Research Department, Western Electric Company. Attendance 155.

Boston.—November 30, 1920, Engineers Club. Paper: "Lightning Protection of Underground Systems." Speaker: Mr. D. W. Roper, Commonwealth Edison Co., Chicago, Ill. Attendance 125.

Cleveland.—November 16, 1920, Club Rooms of Cleveland Engg. Society. Paper: "Searchlight Development at the Lynn Laboratories of the G. E. Co." Speaker: Mr. C. A. B. Halvorson. Attendance 105.

Denver.—November 20, 1920, Metropole Hotel. Mr. H. F. Lunt, Commissioner of Mines for the State of Colorado, gave a very interesting and instructive address on "Electricity in Mining from a Standpoint of Safety." Mr. N. A. Carle also made some interesting remarks concerning the Central Station Operating Code which is in process of development under his supervision. Attendance 23.

Detroit-Ann Arbor.—November 12, 1920, Board of Commerce. Subject: "Characteristics and Applications of Transformers." The discussion was opened by Professor J. C. Parker, of the University of Michigan. A light lunch was served. Attendance 50.

December 3. 1920. Special meeting at the Michigan State Telephone Company; inspection trip through the main exchange dinner in the operators' dining room; talk by Mr. F. C. Kuhn, President of the Company. Attendance 130.

Erie.—November 9, 1920, Erie Public Library. The meeting was held in conjunction with the Engineers Society of Northwestern Pennsylvania. Paper: "Crystal Structure as Shown by X-Rays." Author: Dr. W. P. Davey, Research Laboratory, General Electric Company, Schenectady. Attendance 60.

Fort Wayne.—November 24, 1920, G. E. Co. Subject: "Farm Power and Light Plants." Speaker: Mr. O. E. Archibald, of the General Electric Company. Attendance 75.

Indianapolis-Lafayette.—November 4, 1920, University Club, Ind. Election of officers as follows: Chairman, J. Lloyd Wayne; Secretary, D. C. Pyke. Attendance 33.

Los Angeles.—November 23, 1920, Edison Hall. Subjects: "The Edison Plan, An Adventure in Democracy" by Mr. H. A. Barre; "The Kerckhoff Power Development," by Mr. R. C. Starr. Attendance 102.

Lynn.—November 17, 1920, G. E. Hall. Subject: "Submarine Detection and Acoustical Aids to Navigation." Speaker: Professor G. W. Pierce, of Harvard University. The talk was illustrated by lantern slides which showed the apparatus and illustrated the methods used in sound detection and location. Attendance 250.

Madison.—November 3, 1920, Engg. Bldg., University of Wisconsin. Subject: "Accident Prevention." Speaker: Mr Charles B. Scott, Bureau of Safety, Chicago. Attendance 70.

Milwaukee.—November 24, 1920, City Club. Subject: "The Twentieth Century's Contribution to Our Knowledge of the Atom." Speaker: Dr. R. A. Millikan, Chicago University. Attendance 370.

Pittsburgh.—November 9, 1920, Chamber of Commerce. Subject: "Transmission Lines." Speaker: Mr. M. E. Noyes. Aluminum Company of America. The discussion which followed was very full, the following contributing: Messrs. J. S. Martin, W. Partridge, H. N. Mueller, F. Howard, N. J. Wahberg, H. L. Christie, R. H. Marvin, Sindeband and Jorstad. Attendance 150.

Portland.—November 23, 1920, University Club. Joint meeting of Portland Sections of A. I. E. E. and N. E. L. A., and Oregon Association of Electrical Contractors and Dealers. Mr. G. E. Armstrong, Pacific Coast Editor of the *Electrical World*, gave a most interesting talk on "Northwest Development." A moving picture entitled "The Conquest of the Forest," dealing with electricity in the lumber industry, taking the tree from the time it is felled through the sawmill to the completed house, was shown. Attendance 75.

Providence.—December 3, 1920, Providence Engg. Society Rooms. Subject: "The Manufacture and Application of the Electric Incandescent Lamp." Speaker: Mr. W. E. Smith, of the Bryan-Marsh Division of the National Lamp Works. Attendance 17.

Rochester.—November 26, 1920, Subject: "Valuation of Public Utilities." Speaker: Mr. L. R. Brown, of the New York State Railways. Attendance 24.

St. Louis.—November 17, 1920, Union Electric Hall. Subject: "Illumination." Speaker: Mr. Stickney, of the Edison Lamp Works of General Electric Company, Harrison, N. J. Attendance 80.

San Francisco.—October 29, 1920, Engineers Club. Papers: "Construction of the Kerckoff Power Project of the San Joaquin Light & Power Corporation," by Mr. R. C. Starr: and "Description of a 100,000-Volt Wood Pole Transmission Line and the Economic Questions Governing the Choice of this Type of Construction," by Mr. L. J. Marre. Attendance 115.

Schenectady.—November 19, 1920, Edison Club Hall. Subject: "The Twentieth Century's Contribution to Our Knowledge of the Atom." Speaker: Dr. R. A. Millikan, Professor of Physics of the University of Chicago. Attendance 300.

December 3, 1920, Edison Club Hall. Subject: Modern Photography." Speaker: Mr. Arthur Palme, of the Transformer Engineering Department of the General Electric Company, Pittsfield, Mass. Attendance 275.

Seattle.—November 16, 1920, Bagley Hall, Univ. of Washington. Paper: "Radiant Energy and Its Relation to Matter, Space and Time." Speaker: Mr. J. D. Ross. The paper was illustrated with numerous original lantern slides and experiments with special apparatus to demonstrate several new and startling theories which Mr. Ross advanced. Attendance 500.

Syracuse.—November 17, 1920, Assembly Hall. Subject: "The Engineer and Industry." Speaker: Mr. D. B. Rushmore, of the General Electric Company, Schenectady, N. Y. An informal talk was given by Mr. E. W. Pragst, of the General Electric Company, on "Power Stations." Attendance 152.

Toronto.—November 26, 1920, Toronto University. Paper: "Steam vs. Electrical Drive as Applied to the Steel Industry." Speaker: Mr. E. S. Jefferies. Chief Electrical Engineer of the Steel Company of Canada. Attendance 107.

Utah.—November 16, 1920, Commercial Club. Papers: "Early Electrical Experiences in Utah," by Mr. E. G. Holding; and "Inductive Interference Problems," by Mr. P. A. Jeanne. Attendance 61.

Vancouver.—November 5, 1920. Subject: "Some Features of Electrical Precipitation." Speaker: Dr. J. G. Davidson of the University of British Columbia. Attendance 12.

December 3, 1920. Subject: "Automatic Telephones." Speaker: Mr. E. P. LaBelle, Superintendent of the British Columbia Telephone Company. Attendance 31.

Washington.—November 18, 1920, McKinley Manual Training School. Subject: "The Construction of Controllers for Electric Motors." Speaker: Mr. H. D. James, of the Westinghouse Elec. & Mfg. Co. Attendance 125.

Worcester.—November 30, 1920, Worcester Polytechnic Institute. Subject: "Niagara Power Development." Speaker Mr. J. Allen Johnson, Niagara Falls Power Company. The address was illustrated with motion pictures and stereopticon views. Attendance 105.

PAST BRANCH MEETINGS

Alabama Polytechnic Institute.—November 4, 1920. Professor W. W. Hill made a short but interesting talk on the advantages to be derived by the student in belonging to the Institute. Mr. F. E. Bell also spoke on "The Attitude of Older Engineers towards Students." Attendance 27.

November 18, 1920. Short talks were given by Messrs. J. W. Shealey and H. L. Biggin on "The General Electric Company's Student Course." Attendance 14.

December 2, 1920. Short talks were given on the "Westinghouse Students' Course," by Mr. J. H. Lasseter and Professor W. W. Hill. Professor Hill also gave a short talk on the "Doherty System of Training Graduates." Attendance 26.

University of Arkansas.—November 16, 1920, Engineering Hall. Subjects: "Motor Vehicle—Competer or Ally," by Mr. Shem Hollabough; "600,000-h. p. Line Delivers Niagara Power," by Mr. Jack Thompson; "Ultimate Boiler Capacity Limited by Design and Operation," by Mr. R. Jacobs. Attendance 16.

Armour Institute of Technology.—November 5, 1920. Subjects: "Uses of the Electric Furnace," by Mr. R. J. Grant; "Some Applications of Vacuum Tubes." by Mr. W. W. Pearce; "Electrically Driven Unloading Systems on Lake Vessels," by Mr. M. R. Mehrhof. Attendance 57.

November 19, 1920. Subject: "Burning up a 750-Volt Turbo Alternator." Speaker: Mr. T. E. Grube. Attendance 27.

Brooklyn Polytechnic Institute.—November 12, 1920, Institute Chapel. Joint meeting of Branches of A. I. E. E. and A. S. M. E. The program included introductory talks by the Chairmen of both Branches, motion pictures, and a lecture on "The Engineer's Liability to Failure," by Mr. Herbert A. Wilkinson. Attendance 190.

Bucknell University.—November 22, 1920. Illustrated lecture by Prof. V. B. Hall on "Porcelain Insulators from the Clay Bank to the Cross Arm." Attendance 17.

December 9, 1920. Election of officers as follows: Chairman, L. F. Worthington; Secretary, E. LaRue Worthington. Attendance 8.

California Institute of Technology.—November 19, 1920, Gnome Club House. Talks were given by Professor R. W. Sorensen on "The Present and Past of A. I. E. E."; Professor Franklin Thomas on holding joint meetings of the different engineering societies; and suggestions by Professor George Foster. Refreshments were served. Attendance 27.

University of California.—November 17, 1920. Illustrated talk by Mr. Anderson, Chief Engineer of the Stone & Webster Company, on "The Caribou Plant Development." Attendance 43.

December 1, 1920. Election of officers as follows: Chairman, N. C. Youngstrom; Vice-Chairman, J. N. Kieth; Secretary, P. L. Wyche; Treasurer, F. C. Krasny. Attendance 20.

University of Cincinnati.—November 2, 1920. Subject: "Some Lost Opportunities in Electrical Work." Speaker: Mr. L. T. Milner, President of the Milner Electric Company. Attendance 70.

November 9, 1920. Subject: "Some Mile-Stones in Electrical Work." Speaker: Prof. C. B. Hoffman. Attendance 91.

November 16, 1920. Subject: "The New West End Station of the Union Gas & Electric Company." Speaker: Mr. F. D. Wyatt, of the Union Gas & Electric Company. Attendance 86.

Clemson College.—November 19, 1920. Subjects: "Automobile Ignition," by Mr. W. D. Banks; "Starting and Lighting Systems," by Mr. C. G. Haas; "Current Events," by Mr. C. O. DuRant. Attendance 27.

Drexel Institute.—November 19, 1920. Subject: "Electrical Layout of Large Generating Stations" (with lantern slides). Speaker: Mr. Robert Hentz. Attendance 34.

Georgia School of Technology.—November 18, 1920. Subject: "Long Distance Telephonic Transmission." Speaker: Mr. L. S. Crosby, A. T. & T. Co. Attendance 29.

University of Kansas.—November 20, 1920. Subjects: "Rate Making for Telephone Service," by W. H. Beltz: "Telephone Circuits and Troubles," by H. Havenhill. Attendance 44.

December 1, 1920. Subject: "Telephone Repeaters." Speaker: Seymore Cronk. Attendance 22.

University of Kentucky.—November 15, 1920. Subject: "Development of the Audion Bulb," by E. L. Balch. Paper read from September issue of JOURNAL, "Features of the Substation at the Hog Island Shipyard." Attendance 22.

Lehigh University.—December 10, 1920. Subject: "Outdoor Substations and Switching Equipment" (illustrated). Speaker: Mr. S. Q. Hayes, Westinghouse Company. Attendance 78.

Massachusetts Institute of Technology.—December 9, 1920. Subject: "Homopolar Generator." Speaker: Mr. F. B. Philbrick, Gamewell Fire Alarm Co. Attendance 60.

School of Engineering of Milwaukee.—November 19, 1920. Subject: "Development of Electric Power from Niagara Falls." Speaker: Mr. Joseph Pheiffer, of the American Appraisal Company. Attendance 78.

University of Minnesota.—November 12, 1920. Subjects: "Human Electrons," by Samuel A. Berg; "Summer Experiences in a Small Central Station," by Ralph W. Liddle; "How to Become an Electrical Engineer," by Boyd Phelps. Motion Pictures: "Keokuk Dam," and "Itasca State Park." Refreshments were served. Attendance 50.

University of Missouri.—November 2, 1920. Subject: "Industrial and Commercial Power Rates." Speaker: Mr. Delmar Hasenritter. Attendance 40.

November 15, 1920. Paper on "Cooperation between Engineering Schools and Utilities" (originally prepared by Dean H. B. Shaw) read by Mr. W. C. Wheeler. Attendance 60.

November 22, 1920. Subject: "The Control for Industrial Motors in Industrial Service." Speaker: Mr. R. S. Coulter. Attendance 55.

North Carolina State College.—November 16, 1920. Business meeting. Attendance 33.

November 23, 1920. Captain Cox gave a lecture on "Radio" and accompanied this by a demonstration of apparatus. Attendance 38.

November 30, 1920. Mr. Couch, of the Comberland Railway & Power Company, told of some of his experiences at college and since his graduation. Attendance 35.

University of North Carolina.—November 5, 1920. Subjects: "Before Graduation, What;" by Professor P. H. Daggett; "After Graduation, What?" by Professor J. H. Mustard; "Summer Work, Its Attractions and Advantages," by Mr. Wright; "Enthusiasm, How Obtainable in the Society," by Mr. Wells.

November 19, 1920. Subjects: "Manufacture of Steel Rails," by R. M. Casper; "National Tube Works," by P. C. Smith; "Electrical Factory Work," by M. E. Lake; "Operation of Electrical Machinery," by J. W. Taylor. Attendance 45.

December 3, 1920. Subject: "A modern Telephone Exchange." Speaker: Professor J. E. Lear. Attendance 40.

Ohio Northern University.—December 8, 1920. Subjects: "Metric System," by E. A. Erdman; "Electric Heating," by Everett L. Bird. Attendance 21.

Ohio State University.—November 18, 1920. Talks by students on Summer experiences. Refreshments were served. Attendance 83.

Oklahoma Agricultural and Mechanical College.—December 7, 1920. Subjects: "Cost of Interruptions of Power to Steel Mills," by M. C. Courtney; "Power Development in the Southern States," by Carl Soerner; "Storage of Coal for Central Stations," by C. E. Taylor. Attendance 17.

Oregon State Agricultural College.—November 17, 1920. Subject: "Development of High-Voltage Direct-Current Railways." Speaker: Professor F. O. McMillan. Attendance 63.

University of Pennsylvania.—November 2, 1920. Subject: "Student Course at Westinghouse Elec. & Mfg. Co." Speaker: Mr. G. G. Herrick. Attendance 22.

November 9, 1920. Subject: "Student Course at General Electric Co." Speaker: Mr. R. W. Perkinpine. Attendance 22.

November 16, 1920. Subject: "Power Plants at Niagara Falls." Speaker: Mr. E. C. Muller. Attendance 22.

November 23, 1920. Subject: "Manufacture of Storage Batteries." Speaker: Mr. N. R. Guilbert. Attendance 22.

November 30, 1920. Subject: "Applications of Storage Batteries." Speaker: Mr. J. Austin. Attendance 22.

Purdue University.—November 9, 1920. Subject: "Transformers." Speaker: Mr. E. A. Wagner, of the General Electric Co., Fort Wayne, Ind. Attendance 145.

November 23, 1920. Subject: "Methods of Determining Transformer Costs." Speaker: Mr. J. G. Bailey. Attendance 66.

Rensselaer Polytechnic Institute.—November 9. 1920. Subject: "Electric Propulsion of Ships." Speaker: Mr. Eskel Berg, of the General Electric Company. Attendance 234.

Syracuse University.—November 9, 1920. A short talk on "Radio Telegraphy" was given by Mr. Hines. Attendance 13.

November 16, 1920. Subject: "Vacuum Tubes." Speaker: Mr. Fauss. Attendance 13.

November 30, 1920. Subject: "Electric Furnaces." Speaker: Mr. Chapman. Attendance 13.

Texas Agricultural & Mechanical College.—November 23, 1920. Subjects: "Electrification of Railways—General Views," by Mr. F. E. Woods; "Financing Central Power Stations," by Mr. D. D. Murphree; "The Inspection Trip of the E. E. Juniors of Texas A. & M. College of June 1920," by Mr. A. S. Legg. Attendance 44.

University of Texas.—November 15, 1920. Election of officers as follows: Chairman, C. H. Marshall; Secretary, Treasurer, F. J. Domingues. Attendance 30.

December 6, 1920. Papers: "D-C. Transmission Lines," by O. L. Bryan; "A-C. Transmission Lines" (describing special features of long large capacity lines) by R. S. Munger; "A-C. Transmission Lines" (construction of lines from economic side) by Edward Price; "A-C. Transmission Lines" (featuring maintenance and insulation) by E. W. Franke. Attendance 18.

Virginia Military Institute.—December 3, 1920. Paper read by Mr. Lockey on "Transmission Lines." Illustrated talk by Mr. Bellheimer on the Delco farm lighting plant. Attendance 49.

University of Virginia.—November 11, 1920. Subject: "Inspection Tour of the General Electric Lamp Works, made as Part of Summer School Course of Lehigh University." Speaker: Mr. Gildersleeve. Attendance 14.

University of Washington.—November 9, 1920. Subject: "The Engineer." Speaker: Professor Loew. Attendance 49.

West Virginia University.—November 15, 1920. Subjects: "Object and Work of the American Institute of Electrical Engineers," by Max Wilcoxen; "Gaseous Conductor Light," by J. M. Frum; "Electric Furnaces," by A. C. Price; "Interpoles on Motors," by A. E. LaPoe; "High-Frequency Iron Losses," by R. L. Sheffer; Informal talk by Professor A. H. Forman. Attendance 13.

University of Wisconsin.—December 2, 1920. Subject: "Automatic Telephony and Automatic Telephone Apparatus." Speaker: Mr. R. E. Hantzsch. Attendance 30.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

INSTRUCTORS: All engineers willing to consider teaching positions are invited to register with Engineering Societies Employment Bureau. The Bureau has been called upon to fill more positions, varying in grade from laboratory assistant to heads of departments in various engineering and technical schools of this country, than it has been able to do from among the men now registered. Blanks for purpose of registration and information regarding the Bureau may be had by addressing W. V. Brown, Manager, 29 West 39th Street.

YOUNG MAN with technical training to assist in installation and repairing tower and electric clocks. Experience unnecessary. State age, mechanical and electrical training and salary expected. Location New York City. Z-2609.

MANAGING EDITOR for drug trade Journal. Graduate engineer. Must have managing editorial experience. Location New York City. Z-2592.

INSTRUCTOR IN ELECTRICAL ENGINEERING. Duties beginning in January, 1921, in Technical School, Western Pennsylvania, mainly instructor in Electrical Engineering Laboratory. Graduate of one or two years' experience desired. Z-2595.

CABLE ENGINEER, must be able to write specification, design and give approximate valuation. Application by letter. Only engineer with cable experience will be considered. Permanent position. Location New York City. Z-2569.

SYSTEM OPERATORS. Position similar to that of Load Dispatcher. Men control completely the operation of a 90,000-k. w. system, approximately two hundred miles long in each direction, and including three 30,000-kilowatt plants with many smaller ones, and completely linked together with 66,000 and 110,000-volt transmission system. Should have had enough power house experience to be thoroughly acquainted with operation of large central station and enough electrical experience to enable them to handle the switching, testing, grounding of lines and such similar operation as would arise in handling of such a large transmission system. Prefer technical men, who are able to carry weight with men in charge of large central stations, so that they can give such men instructions in

cases of trouble and command their respect. Position will pay enough to interest men of this calibre and is a splendid opportunity for any one interested in public ulitity work of this nature. Gives opportunity to thoroughly study and handle all of points arising in the operation from the coal pile to the customer. Location Penna. Z-2545.

ELECTRICAL OR MECHANICAL UNIVERSITY GRADUATES wanted for sales work with a well established Electrical manufacturer in the middle west. Correspondence confidential. Give all particulars. Location Mo. Z-2456.

ELECTRICAL ENGINEER with from 4 to 7 years experience in design of direct-current motors and generators of sizes below 5 h. p. State age, education, experience, married or single, and salary expected. Excellent opportunity for man with proper characteristics. Location Penna. Z-2537.

ELECTRICAL ENGINEER. Desirable position open for young engineer on design and application of direct-current and commutating machines below 3 h. p. Should have from 2 to 4 years experience. Specify salary expected, experience, married or not, and education. Location Penna. Z-2538.

INSTRUCTOR in Electrical Engineering. Candidates should be graduates in electrical or mechanical engineering from technical institution of recognized standing. Duties will comprise supervising laboratory experiments, lecturing and holding recitations on laboratory work, and correcting laboratory reports. Work covers ordinary branches of electrical engineering; and it is our custom to change the specific work of each instructor from year to year, so that he will become familiar with all parts. Location New Jersey. Z-2541.

DESIGNING ENGINEERS experienced in electric and mechanical engineering apparatus. Location New York State. Z-2526.

ENGINEERS. A few men with technical training and electrical laboratory experience. The applicant should be familiar with laboratory instruments and possess some ability to engage in development and research work. Location Penna. Z-2531.

SWITCHBOARD ENGINEER OR POWER HOUSE OPERATOR. Wanted, young technically trained engineer with experience as switchboard designer or as power house and substation operator. In reply give experience and age. Location Penna. Z-2532.

ELECTRIC DISTRIBUTION ENGINEER; give salary desired as well as detail information as to training and experience. One to two years experience in either general electric or Westinghouse test department preferred. Graduate electrical engineers of a public utility, also experience in steam work will be an advantage. Location South Carolina. Z-2533.

TECHNICALLY EDUCATED MAN, must have editorial experience, initiative and judgment, for position of responsibility. Replies should embody the essential facts. Z-2497.

INSTRUCTOR of Electrical subjects. Good engineering training and experience. Location Kansas. Z-2507.

INSTRUCTOR in Mining Engineering. Should have a reasonable amount of experience. Location China. Z-2491.

PHYSICIST, who has had doctor degree from two to five years. Experienced in general and electron physics. High grade man wanted. Location New Jersey. Z-2167.

RADIO AND ELECTRIFIERS TUBE ENGINEERS. Should be physicist in Electrical Engineering. Two men needed. One for radio tubes and one for rectifiers. Location New Jersey. Z-2169.

ENGINEER with knowledge of outside wiring to design and develop a line of electric pole line devices for large manufacturing company in central west. Give full details of experience and salary in first letter. Location Pa. Z-2144.

SALES ENGINEER; to sell power house equipment in Detroit. Attractive proposition to experienced man. Give full history and earning capacity in reply. Location Michigan. Z-1931.

ELECTRICAL ENGINEER, must be a college graduate with technical training and must know something about telegraph engineering, preferably having had some practical experience in that line. No one over 35 years of age will be considered. Application by letter only. Location New York City. Z-1936.

YOUNG MAN, about 25 years of age, with an appreciation for and not intolerant to engineering problems. Should know something about magnetic apparatus and be particularly strong on the subject of humidity, how to measure and control it. Location New York City. Z-1672.

INDUSTRIAL PHYSICIST or Engineer interested in research or electrical control problems. Location Middle West. Salary according to training and experience. Location Wisconsin. Z-1525.

DESIGNER, thoroughly familiar with the full line of sockets, receptacles, etc., and with a workable knowledge of the necessary tools and dies. Location New York. Z-2610.

DRAFTSMAN—A large power company in the south has openings for a few graduate engineers and draftsmen with experience in the design of hydroelectric power plants. Give full information in the first letter. Location Ala. Z-2625.

COMMERCIAL RAILWAY ENGINEER—Technical graduate who is interested in railway electrification. Experience along this line is not necessary, but may be an advantage. A man capable of growing into a high class railway salesman and application engineer is desirable. Location Penna. Z-2626.

SUPERINTENDENT for company manufacturing storage batteries. Must have had battery experience. Application by letter giving details. Location New York City. Z-2339.

ELECTRICAL ENGINEER for research work in electrical laboratory. Location Wisconsin. Z-1676.

YOUNG MAN with technical training to assist in installation and repairing tower and electric clocks. Experience unnecessary. State age, mechanical and electrical training and salary expected. Location New York City. Z-2609.

MEN AVAILABLE

YOUNG TECHNICAL GRADUATE, Age 25, single. One year shop experience and six months commercial experience with large electrical manufacturer. Desires position with consulting engineering firm, construction company or industrial plant. E-2443.

ELECTRICAL AND MECHANICAL ENGINEER. Age 32, college education. Twelve years engineering experience, manufacturing, steel plant, R. R., Several years inspector charge of tests and construction. Designer and chief draftsman. Good worker. Desire location as chief draftsman, designer, assistant manager or similar. E-2444.

TECHNICAL GRADUATE, age 25 married. Protestant. Five years experience, draughting, marine work, wiring, electric meters, machine shop, electrical testing. Assoc. A. I. E. E. Desire position with chance for advancement. Available immediately. E-2445.

ELECTRICAL AND MECHANICAL ENGINEER. Ten years practical experience, maintenance street and electric railway rolling stock. Six years practical experience, operation of hydroelectric power plants and substations. Desires responsible position in either of above branches. Good references. Age 30. Now in charge of hydroelectric power plant. Location anywhere. E-2446.

ELECTRICAL ENGINEER AND DRAFTSMAN. Technical graduate. Wide experience in illumination and power design. At present chargeman on electrical design with one of leading shipbuilding concerns. Can produce results. Particularly well adapted for electrical part in connection with merchant shipbuilding. Desires position in or near Philadelphia. E-2447.

ELECTRO-MECHANICAL ENGINEER. Cornell. Age 25. Four years broad experience including two years General Electric Company test. Must locate in immediate vicinity of New York City. Desires position requiring good engineering sense and business ability combined, with good opportunity for advancement. Small growing concern preferred. E-2448.

*ELECTRICAL ENGINEER, technical graduate, with four years experience in details and general problems of telephone and central office engineering. Desires position offering broader opportunity for advancement. Reliable, willing and hard worker. Capable of supervising. Present salary $2700. Available on 30 days notice after latter part of January. E-2449.

SUPERINTENDENT OR ASSISTANT SUPERINTENDENT of medium size or small central station property. Hydroelectric preferred, but not essential. Experience in practically all departments. Age 30, single. Hard worker, technical education. Now assistant superintendent of 1200 kw. system. Can give satisfactory references. Available upon short notice. E-2450.

ELECTRICAL ENGINEER. Seven years experience. Two years station operation, balance station and industrial power design and installation. At present in charge of design and installation of electrical apparatus, power station and plant which it serves. Desires change. Age 29, married. Technical education. Available in two weeks. E-2451.

GRADUATE ELECTRICAL ENGINEER wishes business or engineering position with growing concern near Boston. Six years office and field experience in power plant and distribution design including some mechanical and civil engineering experience. B. S. Tufts College. Familiar with contract work, estimating and power equipment. E-2452.

MECHANICAL ELECTRICAL ENGINEER, technical graduate (1908). Experience covers design, construction, purchasing and operation of mechanical, electrical, hydraulic and refrigerating plants and equipment, also heating and ventilating, and building construction, fire protection, appraisal of engineering properties, investigations and reports. Desire position with consulting engineer or large concern where broad experience is essential. E-2453.

MANAGER, SUPERINTENDENT, or Executive electrical engineer. Technical graduate. Twenty-two years experience in steam and hydroelectric power plants, electric railways systems, high-tension transmission, low-tension distributing system and industrial layouts. Broad experience with public utility. Lately manager and engineer at hydroelectric power plant. Salary commensurate with position. Available immediately. E-2454.

GRADUATE ELECTRICAL ENGINEER with three and one half years' public utility experience in construction and maintenance of street railway and light companies properties. Desires change offering broader opportunities. Salary $200 or thereabout. Experience includes thorough central station and substation work under the Supt. of Line distribution, drafting, accounting and appraisal engineering. E-2455.

ELECTRICAL ENGINEER, age 40. Broad supervisory experience in central station, substation, transmission and industrial constructive, maintenance and operative. Training secured with large public utilities and contracting engineers. Salary $4000. E-2456.

SALES MANAGER or sales engineer, age 36, married. Thoroughly familiar with generally used electrical and mechanical apparatus and many specialties. Understand thoroughly design, manufacturing, installation and operating. E-2457.

TECHNICAL GRADUATE, age 25. B. S. degree in electrical engineering. Would like to locate with concern affording opportunities for the future. Wisconsin or vicinity preferred. Would like to build up in power plant work, but will consider any other good offer. Services available in January. E-2458.

MECHANICAL ELECTRICAL ENGINEER. Twenty years experience in design, development and manufacturing of motors, generators, fractional horse power motors, instruments, wireless apparatus and mechanical and electrical apparatus, and devices of every description. E-2459.

YOUNG ELECTRICAL ENGINEER, 1918. At present employed as purchasing inspector by large interests and desires to stop continuous traveling. Broad practical experience. Familiar with shop production of large power equipment. Wishes position as purchasing engineer or equipment engineer. New York City or vicinity. Present salary equivalent $200 per month. E-2460.

ELECTRICAL SUPERINTENDENT OR MANAGER. Age 36, married. Good personality. Twelve years foreman and superintendent in all classes insulation, construction and maintenance electrical and mechanical. Qualified to oversee large amount of work, both field and office with high efficiency. Exceptional ability for handling men. Now employed. Available on short notice. E-2461.

INDUSTRIAL RESEARCH ENGINEER with associated chemist, desires connection with group of manufacturers for the development and design of special processes and machinery. Cornell graduate 1904. Extensive experience in mechanical and electrical engineering. Preferred location, Central New York. E-2462.

EXECUTIVE POSITION WANTED. Age 33, experienced in steam and hydraulic generation, high-tension transmission and street railway operation. Formerly apprentice with Westinghouse Electric & Mfg. Company. Absolute loyalty to organization. Open for engagement on two weeks notice. At present assistant general superintendent in large power company. E-2463.

ELECTRO-MECHANICAL ENGINEER. Married, age 26. Technical graduate. Designed and built electrical installation at large oil refinery. At present in charge electrical and mechanical work at refinery. Central station experience, boiler operation, stores and accounting supervision, pyrometry expert. Desires executive position in Texas. Minimum salary $3000. E-2464.

ELECTRICAL ENGINEER, age 35. Technical graduate of highest standing. Ten years experience in design of electrical machinery, contributor to technical literature. Desires position in research and development work. E-2465.

ELECTRICAL ENGINEER, graduate 1915. Married, age 31. Seven years experience in construction, operation and maintenance of high and low-tension equipment in large hydroelectric concern. At present in charge of operation and maintenance of hydroelectric station, substations, and large motors in industrial plant. Available 30 days. Salary to be equivalent to $3500. E-2466.

ELECTRICAL ENGINEER. Cornell graduate. 1914 M. E. degree. Three years power plant and three and one-half years in charge operation, maintenance, sales, all electrical equipment, also correspondence and purchasing machinery and supplies. Best references. E-2467.

GRADUATE MECHANICAL AND ELECTRICAL ENGINEER. Age 27. B. Sc. London University. Speaks fluently French and Russian with 2½ years testing experience with leading British firm. Desires progressive post with important American or Canadian firm. E-2468.

ELECTRICAL ENGINEER graduate desires position as assistant in engineering department of some manufacturer of electrical apparatus, or position with public utility. Would also consider position where opportunity is given to develop as sales engineer. Have had varied experience in testing and maintaining electrical apparatus. Age 27. Willing to start at a moderate salary. E-2469.

INSTRUCTOR ELECTRICAL ENGINEER, age 27. Technical graduate, degree B. S. 1917. Desires teaching position in technical school or college in electrical engineering, mathematics or physics. Location in or near New York. E-2470.

ELECTRICAL ENGINEER (general). Technical graduate. Wide practical experience of fifteen years in design, construction, testing and operating of electrical equipment for power stations, substations, factories, private and public plants and railway electrification. Will accept position regardless of locality. New York preferred. E-2471.

MECHANICAL-ELECTRICAL ENGINEER. Services of experienced engineer available for part time to supervise power plant operation and to assist on engineering problems. At present engaged on similar work in industrial plants located in New Jersey and New England, and can furnish credentials from present employers. E-2472.

TECHNICAL GRADUATE (B. S. in Electrical Engineering). Age 31. Desires connections with medium sized or large operating company in capacity of electrical engineer or assistant electrical engineer. Has had general experience in central station distribution and transmission construction, maintenace and operation in all grades from electrician's helper to assistant chief engineer on property of 35,000 kv-a. capacity. Three years as chief engineer for holding company operating in three states. Will consider any location. Available January 15th. E-2473.

ELECTRICAL ENGINEER, with twelve years experience in manufacture, construction, testing, design, etc., of electrical machinery and devices. Eight years teaching experience. At present electrical engineer and works manager with company manufacturing electrical and mechanical devices. Broad experience on efficiency, production and management Desires to connect with progressive company. Open for engagement on four weeks notice. Member A. I. E. E. E-2474.

ENGINEER. Age 32, married. E. E. degree. Desires position with public utility or manufacturer. Trained and equipped for executive, sales, organization and administrative positions. Ten years experience in machine shop, drafting, and seven years business manager of hydroelectric plant serving 40,000 consumers. In charge of new business, contract, accounting, statistical, billing and appliance departments of 125 employees, and one and a half years similar experience with manufacturing company. E-2475.

ELECTRICAL ENGINEER, foreign graduate, age 31, single. Broad engineering experience. At present on development and design of high and extra high voltage apparatus with country's biggest manufacturer. Desires position with large power company. Only position leading to initiative, active and responsible work will be considered. Available on short notice. E-2476.

ELECTRICAL ENGINEER. College graduate 1919, age 24, married. Connection desired with progressive organization preferably west of Chicago, in a sales capacity leading to the position of sales engineer. Good personality, energetic, resourceful and dependable. Year and one-half experience in manufacture of fractional horse-power motors. Some sales experience. Wishes to make connections where unlimited opportunities are afforded. References furnished upon request. E-2477.

MECHANICAL AND ELECTRICAL engineer who has had director of all engineering activities in large industrial organization desires executive position. Has had wide experience in the technical and commercial sides of machinery, manufacture and general production. Has had experience in

power generation and distribution. Has had considerable experience in commercial engineering development with metallurgical and electrochemical industries. E-2478.

ELECTRICAL ENGINEER, graduate of the University of Pennsylvania desires responsible position in the design, construction or maintenance of central and substations. Experienced substation operator anddesigner. Employed at present by prominent consulting power plant engineer for two years. First Lieutenant, Engineer Corps. U. S. Army. Age 30. Single, good executive, good personality. E-2480.

GRADUATE ENGINEER, desires opportunity to learn and grow up with rapidly expanding business, preferably as assistant to production manager. 5½ years general experience, including public utility appraisal, building maintenance and experimental work and supervising design on machine tools. Location preferred New York City or vicinity of Albany, N. Y. E-2479.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Leo Arany, Room 201 Parkway Bldg., Broad & Cherry Sts., Philadelphia, Pa.

2.—James Elliott, Electric Controller & Mfg. Co., Oliver Bldg. Pittsburg, Pa.

3.—Wilfred Langille, Marion Station Public Service Electric Co., Jersey City, N. J.

4.—H. S. Logan, 215-15th Street, Seattle Wash.

5.—Leonard Morey, 1067 East 153rd Street, Cleveland, Ohio

6.—P. J. Reese, 7th & Main Street, Royal Oak, Mich.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED, DECEMBER 10, 1920

ADAIR, SAMUEL E., Electrical Engineer, 1376 Ogden Ave., New York, N. Y.

AMES, ROBERT P., Testing Motors, Century Electric Co., 1827 Pine St.; res., 2608 Locust St., St. Louis, Mo.

ARCHIABLE, GEORGE W., President & General Manager, The Archiable Electric Co., 138 W. 3rd St., Cincinnati, Ohio.

ARNOLD, WILLIAM E., Chief Electrician, Hamilton Woolen Co., Southbridge, Mass.

AYLIFFE, HAROLD E., Head Motor Tester, Century Electric Co.; res., 5841a N. Market St., St. Louis, Mo.

BAKESEF, SAMUEL, Electrical & Mechanical Engineer, 4461 Crocker St., Los Angeles, Cal.

BANGRATZ, ERNEST G., Asst. Electrical Engineer, Jackson & Moreland; res., 19 Hemenway St., Boston, Mass.

BARNETT, BRINKLEY, Asst. Professor of Electrical Engineering Mechanical Hall, University of Kentucky, Lexington, Ky.

BAUER, MILTON EARL, Electrical Testing, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 602 Mulberry St., Wilkinsburg, Pa.

BEREGH, THEODORE J., Electrical Contractor, 461 8th Ave., New York, N. Y.

BLAISDELL, LEONARD T., Manager, General Electric Co., Commercial National Bank Bldg., Washington, D. C.

BOLICK, CLARENCE P., Tester, Westinghouse Elec. & Mfg. Co., East Pittsburgh; res., 818 Holland Ave., Wilkinsburg, Pa.

BORING, MAYNARD M., Asst. General Foreman, Test Dept., General Electric Co., Schenectady, N. Y.

*BOTTIMER, GORDON W., Switchboard Engineering Dept., General Electric Co.; res., 306 Campbell Ave., Schenectady, N. Y.

BRENNAN, GERARD, Laboratory Asst., New York Edison Co., 92 Vandam St.; res., 51 Bradhurst Ave., New York, N. Y.

BROWN, PLINEY B., Supt., Power House, Sanitary District, Lockport, Ill.; res., Joliet, Ill.

BRUBAKER, HENRY W., General Supt., Edison Electric Co., Conestoga, Bldg., Lancaster, Pa.

BUTTNER, HAROLD H., Asst. Electrical Engineer, Lafayette Radio Station, 8 Rue Colmar, Bordeaux, France.

CAREY, THOMAS E., Assignment Man, Mountain States Tel. & Tel. Co., 1175 Osage Ave., Denver, Colo.

CARISS, CARINGTON C., Estimating Engineer, Waterous Engine Works Co., Ltd.; res., 95 William St., Brantford, Ont.

CASTELLS, ARMANDO, Test Dept., General Electric Co., P. O. Box 871, Schenectady, N. Y.

CHENEY, STUART K., Demonstrator, Electrical Engineering Dept., University of Toronto; res., 127 Givens St., Toronto, Ont.

CUDDY, EDWARD M., Manager, Electrical Dept., Syracuse Supply Co., 314 W. Fayette St., Syracuse, N. Y.

CURRIN, ROBERT H., Electrician, Sanders Electrical Co., 425 Stark St., Portland, Ore.

DOI, MASAJI, Electrical Engineer, Mitsubishi Mining Co., Mitsubishi Namazuta Colliery, Fukuokaken, Japan.

ELLIOTT, JOHN S., Manager, Coto-Coil Co., 87 Willard Ave., Providence, R. I.

ELSBERRY, ARTHUR D., Commercial Engineer, The Union Gas & Electric Co., 4th & Plum Sts., Cincinnati, Ohio.

EVANS, A. EMERSON, Engineering Asst., Bell Telephone Co. of Pennsylvania; res., 149 Hansberry St., Germantown, Philadelphia, Pa.

FEINSILBER, MURRAY, Power Plant Designer, T. E. Murray Co. Inc., 55 Duane St.; res. 830 E. 170th St., New York, N. Y.

FENDRICH, WILLIAM, Jr., Electrical Inspector, U. S. Navy, 44 Court St., Brooklyn, N. Y.; res., 530 Upper Mountain Ave., Upper Montclair, N. J.

FERGUSON, D. C., Chief Draftsman, Beattie McIntyre, Ltd. 72 Victoria St.; res. 2274 Queen St. East, Toronto, Ont.

FLAKE, G. RAYMOND, Chief Electrician, Standard Steel Works Co., Burnham, Pa.

FLYNN, CHARLES C., Electrical Engineering Dept., Ford Motor Co.; res., 2940 E. Grand Blvd., Detroit, Mich.

FOLEY, JAMES J., President & General Manager, Buckeye Equipment Co., 26 W. 3rd St., Cincinnati, Ohio.

FURUKAWA, YOSHIKICHI, Director & Chief Engineer, Kyusuhu Electric Light & Traction Co., Fukuoka, Japan.

GARNER, CLARENCE L., Wire Chief, Washington Coast Utilities, Portage, Wash.

GEALY, EDGAR J., Asst. Electrical Engineer, Lehigh Valley Coal Co., Wilkes-Barre; res., 222 Pierce St., Kingston, Pa.

GEYER, DELBERT G., Asst. Manager, Electrical Dept., Syracuse Supply Co.; res., 412 Stinard Ave., Syracuse, N. Y.

GRAHAM, GEORGE A., Electrical Engineer, Signal Corps, U. S. Army, 1710 Penn. Ave., N. W., Washington, D. C.; res., Baltimore, Md.

GRAVES, ELWOOD L., Instructor, Bliss Electrical School, Washington, D. C.

GREEN, JOHN C., Engineer Inspector, The B. F. Goodrich Rubber Co.; res., 200 W. Chestnut St., Akron, Ohio.

*GUARD, JAMES R., Erecting Engineer, General Electric Co., Witherspoon Bldg., Philadelphia, Pa.

GUHA, DEVENDRA N., President, Hindusthan Electric Co., Calcutta, India.

HACKING, JOHN, Electrical Engineer, Merz. & McLellan, V. Gomez 2807, Buenos Aires, A. R.

*HAMMOND, JACKSON A., Sales Engineer, Westinghouse Elec. & Mfg. Co., 502 Law & Commerce Bldg., Bluefield, W. Va.

HATTORI, KATSUO, Engineer, Shibaura Engineering Works, Kanasugi, Shiba, Tokyo, Japan.

HAYASHI, SEIICHIRO, Electrical Engineer, Furukawa & Co. Ltd., Marunouchi, Tokio, Japan.

HEADINGS, WILLIAM W., Chief Engineer, Carballoy Products Co.; res., 512 Castalia St., Bellevue, Ohio.

HEINZERLING, THEODORE W., Partner, Firm of Bennett & Heinzerling; res., 5720 6th Ave., Brooklyn, N. Y.

HENDRIXSON, BURTON C., Sales Engineer, Buckeye Equipment Co., 26 W. 3rd St., Cincinnati, Ohio.

HENNINGER, ALAN E., Testing Dept., General Electric Co., P. O. Box 609, Schenectady, N. Y.

HOEFER, FRED S., Instructor, Electrical Engineering Dept., Cornell University; res., 200 Willard Ave., Ithaca, N. Y.

HOLROYD, GEORGE E., Foreman, Electrical Dept., Swift & Co.; res., 820 E. 64th St., Chicago, Ill.

HORN, ALBERT F. E., Salesman, General Electric Co., Commercial National Bank Bldg., Washington, D. C.

HUGHES, HAROLD S., Electrical Dept., Q. M. C., U. S. A., Camp Signal Office, Camp Funston, Kansas.

HUSTON, ELBERT L., Commercial Engineer, Union Gas & Electric Co., Cincinnati, Ohio.

HUTH, EDWIN C., Sales Engineer, Century Electric Co., 710 Traction Bldg., Cincinnati, Ohio.

IMAI, MASAKAZU, Chief Electrical Engineer, South Manchurian Railway Co., Darien, Manchuria.

ISONO, TATSUICHIRO, Engineer, Shibaura Engineering Works, Kanasugi, Shiba, Tokyo, Japan.

JOHNSON, FREDERICK H., Laboratory Tester, Standards Laboratory, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

JOHNSON, JAMES A., Supt., Canadian Crocker-Wheeler Co., Ltd., St. Catharines, Ont.

JONES, ROY S., Electrical Engineer, British Thomson-Houston Co.; res., 131 Murray Road, Rugby, England.

KEETCH, HARRY L., Works Manager's Dept., National Carbon Co., Cleveland; res., 1193 Cranford Ave., Lakewood, Ohio.

KELLY, JOHN E., Secretary, The Southland Products Co., Inc., Humboldt, Tenn.

KELLY, JOSEPH W., Supt., Municipal Light & Water Plant, Algona, Iowa.

KENNEDY, JAMES E., Asst. Division Supt., Southern Power Co., Great Falls, S. C.

KER, MONTGOMERY, Electrical Engineer, The Worcester Woolen Mill Co., Southgate Place; res., 11 Crown St., Worcester, Mass.

KINDY, WARD B., Instructor, Electrical Engineering Dept., Iowa State College, Ames, Ia.

KOMARU, TODA, Electrical Engineer, Mitsubishi Zosen Kabushiki Kaisha Electrical Works, Kobe, Japan.

KONZE, JOHN E., General Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 415 Kelly St., Wilkinsburg, Pa.

KRAFT, AUGUST C., Engineer, Humble Oil & Refining Co., Houston, Texas.

KUHL, FRANK, Electrical Engineer, Pratt Engineering & Machine Co.; res., 422 E. 81st St., New York, N. Y.

LEWIS, WILLIAM G., Power Engineer, Knowlton Bros. Paper Co., Inc., Watertown, N. Y.

LINDSTROM, NILS O., Works Manager, Pacific Ave. & Forest St., Jersey City; res., 121 High St., Nutley, N. J.

LORD, LESLIE MOLINEAUX, 2nd Asst. Electrician, S. S. Leviathan, Hoboken, N. J.

LYDALL, CHAS. H., Electrical Engineer, Merz & McLellan, V. Gomez 2807, Buenos Aires, A. R.

MACDONALD, C. HOLMES, Sr., Engineering Assistant, Bell Telephone Company of Pennsylvania, 19 S. 2nd St., Harrisburg, Pa.

MANDEVILLE, FRANCIS T., Shift Engineer, Radio Corp. of America, Radio Station, New Brunswick, N. J.

MASON, LAVATER W., Meter Tester, Fall River Electric Light Co.; res., 380 Bradford Ave., Fall River, Mass.

McCALL, MALCOLM, Asst. Engineer to Consulting Engineer, The United Light & Power System, Abilene, Kan.

McCOY, JAMES L., Traffic Engineer, Bell Telephone Company of Pa., 253 N. Broad St., Philadelphia, Pa.

McDUFFEE, EARL L., Draftsman, Lockwood, Greene & Co., 822 Book Bldg., Detroit, Mich.

McINTYRE, A. B., Motor Testing, Century Electric Mfg. Co.; res., 4114A Grove St., St. Louis, Mo.

MEYERHOFF, LOUIS, Asst. Electrical Engineer, Crown Cork & Seal Co.; res., 2309 Druid Hill Ave., Baltimore, Md.

*MICHELL, HUMFREY G., Test & Inspecting Engineer, City of Winnipeg Light & Power Dept.; res., 314 Maryland St., Winnipeg, Manitoba.

MILLER, HERBERT E., Asst. Chief Electrician, Pullman Car Co., Pullman, Ill.

MILLS, EDWIN S., Division Foreman, Electrical Dept., Pacific Electric Railway, Los Angeles; res., 1544 3rd St., Santa Monica, Cal.

MONESMITH, ERLE R., Asst. Instructor, Machine Laboratory, Bliss Electrical School, Washington, D. C.

MOORE, EARL S., Sales Engineer, Century Electric Co., 1827 Pine St., St. Louis, Mo.

MORAVECKY, FRANK J., Draftsman, Westinghouse Elec. & Mfg. Co.; res., 6601 Hedge St., Pittsburgh E. E., Pa.

NAVARRO, JUSTO LOPEZ, Electrical Engineer, Philippine Engineering Company, Manila, P. I.

NICHOLSON, ARTHUR T., Salesman, Syracuse Supply Co.; res., 342 Emma St., Syracuse, N. Y.

NORREGAARD, HANS J., Draftsman, New York Edison Co.; res., 3675 Broadway, Apt. 9, New York, N. Y.

OATES, EARL STANLEY, Electrical Engineer, Stone & Webster, Inc.; res., 2007 Diamond St., Philadelphia, Pa.

O'BRIEN, WM. L., Motor Testing, Century Elec. Mfg. Co.; res., 4167 Castleman Ave., St. Louis, Mo.

O'DONNELL, HAROLD L., Supervisor in Army Electrical School, Camp Grant, Ill.

OKADA, HISASHI, Engineer, Shibaura Engineering Works, Kanasugi, Shiba, Tokyo, Japan.

PETERSON, CHESTER A., Tester (Electrician), Safety Insulated Wire & Cable Co.; res., 83 W. 11th St., Bayonne, N. J.

PHILLIPS, LESLIE, Assistant Engineer, Stone & Webster, Boston; res., 33 Grove St., W. Lynn, Mass.

PICKENS, J. FENTON, Asst. Instructor in Electrical Tests, Bliss Electrical School, Washington, D. C.

PIERCE, LEWIS E., Field Engineer, New England Tel. & Tel. Co., 26 Mechanic St., Worcester, Mass.

PITMAN, IRVING G., Instrument Inspector, New York Edison Co., 92 Vandam St., New York; res., 345 Washington St., Newark, N. J.

PRICE, RALPH F., Industrial Engineer, Century Electric Co.; res., 3800 4th St., Des Moines, Iowa.

RANKIN, HARRY M., Lighting Dept., General Electric Co., Schenectady, N. Y.

RAYMOND, CHESTER A., Instructor, Wiring & Meter Testing Dept., Bliss Electrical School, Washington, D. C.

RICE, FRANKLIN S., Engineer, Operating Dept., Great Northern Power Co., Duluth, Minn.

ROCHE, THOMAS F., Electrical Instructor, State Trade School, Putnam, Conn.; 143 Eagle St., North Adams, Mass.

ROMZICK, LAWRENCE H., Electrical Draftsman, Lockwood, Greene & Co., 822 Book Bldg., Detroit, Mich.

RYPINSKI, CHANDOS A., Electrical Draftsman, Engineering Division, Otis Elevator Co.; res., 550 W. 172nd St., New York, N. Y.

SCHACHTE, WILLIAM L., Transformer Engineer, General Electric Co.; res., 68 Northumberland Road, Pittsfield, Mass.

SCHUBERT, WALTER C., Asst. Chief Electrician, Ajax Rubber Co.; res., 2349 Hanson Ave., Racine, Wis.

SCOTT, RALPH Y., Engineer, New England Tel. & Tel. Co., Room 808-50 Oliver St., Boston, Mass.

SEARING, HUDSON R., Radio Engineer, U. S. Army Air Service, Aviation General Supply Depot, Fairfield, Ohio.

SMITH, DAVID D., Motor Tester, Century Electric Company; res., 5252 Paulian Pl., St. Louis, Mo.

SMITS, THEODORE A., Instructor in Physics, University of Pennsylvania, Philadelphia, Pa.

*SONNEBORN, DAVID B., Sales & Prod. Manager, Voltamp Electric Mfg. Co., & Chloride of Silver Dry Cell Battery Co. 407-409 N. Paca St., Baltimore, Md.

STEVENSON, H. A., District Manager, Allen-Bradley Co.' 1115 Citizens Bldg., Cleveland, Ohio.

STONE, ELLERY W., General Manager, Pacific Radio Supplies Co., 638 Mission St., San Francisco, Cal.

STRATTON, D. R., Electrician, Hydro Electric Sta., Winnipeg Electric Railway Co., Pinawa, Man., Can.

SULLIVAN, JAMES D., Chief Electrician, Ray Consolidated Copper Co., Box 625, Hayden Ariz.

SWENSON, LEON G., Chief Electrician, Worcester Gas Light Co., Worcester; res., Oak St., Shrewsbury, Mass.

TENNYSON, ALFRED L., Demonstrator, Electrical Engineering Dept., University of Toronto, Toronto; res., Port Perry, Ont.

TREWMAN, HARRY F., Chief Instructor of Electrical Engineering, Ordnance College, Woolwich, London, Eng.

TRIMMING, PERCY H., Chief Electrician, Dominion Flour Mills, Ltd., Montreal; res., 670 Joseph St., Verdun, Montreal, P. Q.

WAINWRIGHT, EARL M., Electrical Construction, E. I. Du Pont Co. Dye Works, Deepwater Point; res., 70 Penn. St., Penns Grove, N. J.

WANG, HAN CHEN, Student, Harvard University; res., 32 Gorham St., Cambridge, Mass.

WANGMAN, ARTHUR R., Electrical Engineering Dept., Lockwood, Greene & Co.; res., 8658 Epworth Blvd., Detroit, Mich.

WEBBER, GEORGE, E. F., Electrical Engineer, Merz & McLellan, V. Gomez 2807, Buenos Aires, A. R.

WEBSTER, ALFRED F., Jr., Chief Electrician, Crown Cork & Seal Co.; res., 118 S. 5th St., South Baltimore, Md.

WEBSTER, WALTER L., Electrical Engineer, Lockwood, Greene & Co.; res., 882 Manistique Ave., Detroit, Mich.

WHITE, GEORGE P., Engineering Work, American Tel. & Tel. Co., 500 Stahlman Bldg., Nashville, Tenn.

WOODRUFF, L. F. 2nd, Test Man, General Electric Co., Schenectady, N. Y.

WRESSELL, EDMUND F., Chief Electrician, Mechanical & Electrical Dept., Iowa Railway & Light Co., Cedar Rapids, Iowa.

WUNDER, EUGENE G., Fieldman, The Pacific Tel. & Tel. Co., 1102 Telephone Bldg., Portland, Ore.

ZANGLER, HERBERT, Erecting Engineer, Construction Dept., General Electric Co., Schenectady; res., Croton-on-Hudson, N. Y.

ZEHRING, RAYMOND W., Northwest Representative Habirshaw Electric Cable Co.; res., 5003 18th N. E., Seattle, Wash.

ASSOCIATES REELECTED DECEMBER 10, 1920

BEAUCHAMP, LEON, Manager, & Elec. Engr., Standard Construction Co., Montreal Que.

VATTER, WILBUR L., Division Supervisor of Equipment, Western Union Telegraph Co., 302 Broadway, New York, N. Y.

MEMBERS ELECTED DECEMBER 10, 1920

ADAMS, WILLARD C., Electrical Engineer, Allen & Garcia, 21 East Van Buren St., Chicago, Ill.

AVERY, WILLIAM Y., Sales Engineer, Electro-Dynamic Co., Bayonne; res., 9 Washington Place, Cranford, N. J.

STOFFLET, HOWARD A., Motive Dept., Philadelphia & Reading Railway Co., Reading, Pa.

TRANSFERRED TO GRADE OF MEMBER DECEMBER 10, 1920

BENJAMIN, REUBEN B., President, Benjamin Electric Mfg. Co., Chicago, Ill.

BILLIP, ERNEST H., Partner with J. J. Naugle, New York, N. Y.

BOVEE, BENEDICT A., Professor of Experimental Electrical Engineering, School of Engineering, Milwaukee, Wis.

BRADEN, NORMAN S., Vice-President, Canadian Westinghouse Co. Ltd., Hamilton, Canada.

BUCHANAN, EDWARD V., General Manager, Public Utilities Commission, London, Ontario.

CARLSON, FREDERICK, W., Supt. of Electrical Dept., Davison Chemical Co., Curtis Bay, Md.

ELLIOTT, LOUIS, Steam Plant Engineer, Electric Bond & Share Co., New York, N. Y.

FLANDERS, CHARLES K., Captain, Signal Corps, U. S. A. New York, N. Y.

GARLINGTON, A. C., Supt. of Construction & Maintenance, Elec. Div., Panama Canal, Balboa, C. Z.

GIBBS, GEORGE S., Sales Engineer, Representative, Westinghouse Elec. & Mfg. Co., Boston, Mass.

HERTNER, JOHN, H., President, Hertner Electric Co., Cleveland, O.

NEILD, JAMES F., Supt. of Substations, Toronto Railway Co., Toronto, Ont.

OLSEN, VALDEMAR, Meter Engineer, Shanghai Municipal Council, Electricity Dept., Shanghai, China.

RADBONE, VICTOR, J., Sales Engineer, Int'l General Electric Co., London, England.

ROBERTS, EDWARD A., Engineer, John A. Beeler, New York, N.Y

SCHWARZE, FRED, Electrical Engineer, Pfister & Vogel Leather Co., Milwaukee, Wis.

SHUCK, GORDON R., Instructor in Electrical Engineering, University of Washington, Seattle, Wash.

UPSON, WALTER L., Professor Electrical Engineering, Washington University, St. Louis, Mo.

WOOLHISER, H. L., Business Manager, Village of Winnetka, Winnetka, Ill.

TRANSFERRED TO GRADE OF FELLOW, DECEMBER 10, 1920

BIRD, WILLIAM L., Manager, Secretary, Director, Kaministiquia Power Co., Fort William, Ont.

BRANDON, EDGAR T. J., Electrical Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

MOREHOUSE, LYMAN F., Equipment Development Engineer, American Telephone & Telegraph Co., New York, N. Y.

WYNNE, FRANCIS E., Manager, Railway Equipment Engineering Dept., Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held November 29, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

GRAY, GEORGE F., Assistant Manager, Engineering Dept., National Analine & Chemical Co., New York, N. Y.

HAZELTINE, LOUIS A., Professor of Electrical Engineering, Stevens Institute of Technology, Hoboken, N. J.

OSBORNE, HAROLD S., Transmission Engineer, American Telephone & Telegraph Co., New York, N. Y.

WATER, GRANVILLE A., Assistant Chief Engineer, Wagner Electric Mfg. Co., St. Louis, Mo.

WOODBRIDGE, J. LESTER, Chief Engineer, Electric Storage Battery Co., Philadelphia, Pa.

To Grade of Member

APPLEYARD, ARTHUR E., Manager, Minneapolis Anoka & Cuyuna Range Ry. Co.; President, British Columbia & Alberta Power Co. Ltd.; Minneapolis, Minn.

BARNS, BIRD L., A. C. Engineer, Canadian General Electric Co., Peterborough, Ont.

BERNHARD, FRANK H., Editor, E. M. F. Electrical Year Book, Electrical Trade Publishing Co., Chicago, Ill.

CARPENTER, HENRY C., Chief Engineer, New York Telephone Co., New York, N. Y.

EVANS, PORTER H., Engineering Dept., Western Electric Co., New York, N. Y.

FECHT, ARTHUR J., Associate Electrical Engineer, Bureau of Standards, Washington, D. C.

GROSS, BENJAMIN, Chief Engineer, Hatzel & Buehler, Inc., New York, N. Y.

HANNAFORD, FOSTER, General Manager, Twin City Rapid Transit Co., Minneapolis, Minn.

HERRMANN, RAYMOND R., Instructor in Mathematics and Mechanics, University of Minnesota, Minneapolis, Minn.

LEE, CARL, Electrical Engineer, Peabody Coal Co., Chicago, Ill.

PETTY, EDWIN W., Electrical Engineer, H. M. Byllesby Co., Chicago, Ill.

POMEROY, WILLIAM D., Vice-President and General Manager, Goulds Manufacturing Co., Seneca Falls, N. Y.

POOL, RALPH Y., General Superintendent, Intermountain Railway Light & Power Co., Colorado Springs, Colo.

STICKNEY, H. RUSSELL, Electrical Engineer, Jackson & Moreland Boston, Mass.

STOKES, STANLEY, General Supt. Outlying Plants, Union Electric Light & Power Co.; Vice-President & General Manager, Commercial Telephone Co.; St. Louis, Mo.

WHALEN, JAMES M., Vice-President & Manager of Machine Dept., Northwestern Electric Equipment Co., St. Paul, Minn.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member, objecting to the election of any of these candidates should so inform the Secretary before January 31, 1920.

Allen, Alex. D., Hamilton, Ont.
Ayles, Jesse A., Boston, Mass.
Beedle, A. L., Cincinnati, Ohio.
Behner, Leroy, Pittsburgh, Pa.
Behnke, R. E., New York, N. Y.
Berton, Philip L., Montreal, Que.
Blaisdell, Colborn E., Dover, N. H.
Bliss, Ernest F., East Moriches, L. I., N. Y.
Bodicky, Andrew, St. Louis, Mo.
Boyer, William H., Portland, Ore.
Bright, Jacob, Philadelphia, Pa.
Brown, Ellsworth A., Syracuse, N. Y.
Bruns, Harry, New York, N. Y.
Calhoun, Ernest N., Milwaukee, Wis.
Capwell, Elmer A., Anthony, R. I.
Carrothers, John W., Kansas City, Mo.
Carter, Philip S., New York, N. Y.
Casselberry, Charles L., Syracuse, N. Y.
Clements, William R., (Member), Dayton, Ohio.
Cogan, Nyles M., Boston, Mass.
Cook, Querin H., Chicago, Ill.
Cotterman, Leo K., Manila, P. I.
Cotting, Paul M., Boston, Mass.
Cowie, Hugh, Peterboro, Ont.
Cronkite, Minton, New York, N. Y.
Darling, John A., Schenectady, N. Y.
Davis, R. J., St. Louis, Mo.
Degnan, Robert E., New York, N. Y.
Dickinson, Wilbur K., Lynn, Mass.
Dole, Sanford B., San Francisco, Cal.
Dunkle, Clarence C., Kellogg, Idaho.
Dyer, John B., (Member), Ferguson, Mo.
Elliot, Andrew H., Montreal River, Ont.
Engle, Melvin D., Baltimore, Md.
Euston, Jacob H., Ann Arbor, Mich.
Fairlie, Howard W., Montreal, Que.
Fariss, T. McL., St. Louis, Mo.
Ferguson, John R., New York, N. Y.
Ferlic, Andrew J., E. Pittsburgh, Pa.
Fonseca, Arthur W., Portland, Ore.
Fonsica, Edward L., Newark, N. J.
Fraser, William W., Schenectady, N. Y.
Gardner, William G., Philadelphia, Pa.
Gavin, Robert G., Montreal, Que.
George, Beauford J., Kansas City, Mo.
George, R. B., Agricultural College, Miss.
Gilbert, Frederick W., Schumacher, Ont.
Gillmore, Reginald W., W. Lynn, Mass.
Gilt, Carl M., Schenectady, N. Y.
Glennie, Alfred G., Hartford, Conn.
Goljenboom, George, Milwaukee, Wis.
Goodale, Josiah E., Long Island City, N. Y.
Gray, Cecil, Baltimore, Md.
Griest, George W., Lancaster, Pa.
Griffin, John F., Valparaiso, Ind.
Grush, Henry G., Boston, Mass.
Hackett, J. Henry, Philadelphia, Pa.
Hackett, John W., New York, N. Y.
Haislip, Richard A., New York, N. Y.
Hallett, William S., Cobalt, Ont.
Hammerton, William G., Toronto, Ont.
Harrison, John A., (Member), Lima, Ohio.
Hawley, Howard B., Cobalt, Ont.
Hawthorne, Jack A., New York, N. Y.
Healey, Rolla E., Boston, Mass.
Heidenrich, George E., Cleveland, Ohio.
Heinemann, J. Robert, Schenectady, N. Y.
Hill, Walter L., San Jose, Cal.
Hollender, William, Brooklyn, N. Y.
Howard, James P., Winnipeg, Manitoba.
Hudson, Walter F., Utica, N. Y.
Hymes, Harry, E. Pittsburgh, Pa.
Isley, Cary T., Wadesboro, N. C.
Jacobs, Arthur R., Chicago, Ill.
James, Carl P., Philadelphia, Pa.
Johnson, Herbert M., Worcester, Mass.
Jones, Gerald L., Peterboro, Ont.
Jones, Herndon C., Hollidays Cove, W. Va.
Jones, Julian D., Philadelphia, Pa.
Jones, William S., Washington, D. C.
Kalbach, Stanley M., (Fellow), Baltimore, Md.
Kapp, Cecil A., Atlanta, Ga.
Keeley, Henry J., Denver, Colo.
Kennedy, Thomas W., Schenectady, N. Y.
Kinley, Clifford B., Toledo, Ohio.
Klingman, Loren E., Ft. Wayne, Ind.
Krouss, William A., Pittsburgh, Pa.
Lake, Charles J., Philadelphia, Pa.
Lemmon, Walter S., New York, N. Y.
Lemon, Alonzo L., Schenectady, N. Y.
Leonard, William E., Boston, Mass.
Loewenthal, George G., Pueblo, Colo.
Long, Ralph E., E. Pittsburgh, Pa.
Loughead, Robert C., Detroit, Mich.
Lowcook, Henry, Milwaukee, Wis.
Lueking, Lancelot L., St. Louis, Mo.
Luenebrink, Chester F., St. Louis, Mo.
Luney, Oswald S., Niagara Falls, Ont.
Lynde, Walter L., Beaver Dam, Ohio.
MacDonald, Russell, Philadelphia, Pa.
Marsh, E. L., Schenectady, N. Y.
Marson, Arnaldo, New York, N. Y.
Mason, Roy W., Pittsfield, Mass.
Matthews, Charles H., (Member), Cleveland, Ohio.
Mayer, George H., Stevens Point, Wis.

12502 Giordmaina, John N., Toronto Central School

Total 443.

OFFICERS of A. I. E. E. 1920-1921

PRESIDENT
(Term Expires July 31, 1921)
A. W. BERRESFORD

JUNIOR PAST-PRESIDENTS
(Term expires July 31, 1921) COMFORT A. ADAMS
(Term expires July 31, 1922) CALVERT TOWNLEY

VICE-PRESIDENTS
(Terms expire July 31, 1921)
CHARLES S. RUFFNER
CHARLES ROBBINS
L. T. ROBINSON
C. E. MAGNUSSON
E. H. MARTINDALE
C. S. McDOWELL

MANAGERS
(Terms expire July 31, 1921)
WALTER A. HALL
WILLIAM A. DEL MAR
WILFRED SYKES

(Terms expire July 31, 1922)
WALTER I. SLICHTER
G. FACCIOLI
FRANK D. NEWBURY

(Terms expire July 31, 1923)
L. E. IMLAY
F. F. FOWLE
L. F. MOREHOUSE

(Terms expire July 31, 1924)
HAROLD B. SMITH
JAMES F. LINCOLN
E. B. CRAFT

TREASURER / **SECRETARY**
(Terms expire July 31, 1921)
GEORGE A. HAMILTON / F. L. HUTCHINSON

HONORARY SECRETARY
RALPH W. POPE

GENERAL COUNSEL
PARKER and AARON,
66 Broad Street, New York.

PAST PRESIDENTS—1884-1920

*Norvin Green, 1884-5-6.
*Franklin L. Pope, 1886-7.
T. Commerford Martin, 1887-8.
Edward Weston, 1888-9.
Elihu Thomson, 1889-90.
*William A. Anthony, 1890-91.
Alexander Graham Bell, 1891-2.
Frank Julian Sprague, 1892-3.
*Edwin J. Houston, 1893-4-5.
*Louis Duncan, 1895-6-7.
Francis Bacon Crocker, 1897-8.
A. E. Kennelly, 1898-1900.
Carl Hering, 1900-1.
Charles P. Steinmetz, 1901-2.
Charles F. Scott, 1902-3.
Bion J. Arnold, 1903-4.
John W. Lieb, 1904-5.
Schuyler Skaats Wheeler, 1905-6.
Samuel Sheldon, 1906-7.
*Henry G. Stott, 1907-8.
Louis A. Ferguson, 1908-9.
Lewis B. Stillwell, 1909-10.
Dugald C. Jackson, 1910-11.
Gano Dunn, 1911-12.
Ralph D. Mershon, 1912-13.
C. O. Mailloux, 1913-14.
Paul M. Lincoln, 1914-15.
John J. Carty, 1915-16.
H. W. Buck, 1916-17.
E. W. Rice, Jr., 1917-18.
Comfort A. Adams, 1918-19.
Calvert Townley, 1919-20.

*Deceased.

LOCAL HONORARY SECRETARIES

Charles le Maistre, 28 Victoria St., London, S. W., England.
Guido Semenza, N. 10 Via S. Radegonda, Milan, Italy.
Robert Julian Scott, Christchurch, New Zealand.
T. P. Strickland, 61 Hunter St., Sydney, N. S. W.
W. G. T. Goodman, Adelaide, South Australia.
L. A. Herdt, McGill Univ., Montreal, Que.
A. S. Garfield, 10 Rue de Londres, Paris, France.
Harry Parker Gibbs, Tata Hydroelectric Power Supply Co., Ltd., Bombay, India.
John W. Kirkland, Johannesburg, South Africa.

A. I. E. E. COMMITTEES

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

A. W. Berresford, Chairman, Cutler-Hammer Mfg. Co., Milwaukee, Wis.
G. A. Hamilton, L. T. Robinson, W. I. Slichter, L. F. Morehouse, C. S. Ruffner, Calvert Townley.

FINANCE COMMITTEE

Charles Robbins, Chairman, W. E. & M. Co., E. Pittsburgh, Pa.
L. F. Morehouse, C. S. Ruffner.

MEETINGS AND PAPERS COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York, N. Y.
L. W. Chubb, E. E. F. Creighton, Charles Robbins, J. C. Clark,
Chairman of Committee on Coordination of Institute Activities.
Chairmen of the Technical Committees.
Chairmen of all Sections.

PUBLICATION COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
W. A. Del Mar, A. S. McAllister, W. I. Slichter, F. L. Hutchinson, Charles Robbins.

COMMITTEE ON COORDINATION OF INSTITUTE ACTIVITIES

L. T. Robinson, Chairman, General Electric Co., Schenectady, N. Y.
N. A. Carle, F. L. Hutchinson, W. I. Slichter, Charles Robbins.

BOARD OF EXAMINERS

Clayton H. Sharp, Chairman, 556 E. 80th St., New York, N. Y.
Wm. A. Del Mar, J. H. Morecroft, E. M. Sawtelle, Erich Hausmann, H. H. Norris, H. S. Wynkoop, H. N. Latey, N. L. Pollard.

SECTIONS COMMITTEE

John B. Fisken, Chairman, Box 2158, Spokane, Wash.
C. F. Harding, Vice-Chairman.
W. A. Hall, J. C. Parker, J. Lloyd Wayne.

COMMITTEE ON STUDENT BRANCHES

C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
Harold B. Smith, A. C. Lanier, C. F. Scott, C. E. Magnusson

MEMBERSHIP COMMITTEE

E. H. Martindale, Chairman, Martindale Electric Co., Station G, Cleveland, O.
F. S. Hartman, R. W. Krass, G. E. Stoltz, G. D. Y. Leacock,
Chairmen of Membership Committees of all Sections

PUBLIC POLICY COMMITTEE

H. W. Buck, Chairman, 49 Wall St., New York, N. Y.
C. A. Adams, Gano Dunn, Wm. McClellan, N. A. Carle, John W. Lieb, C. E. Skinner.

LAW COMMITTEE

H. H. Barnes, Jr., Chairman, 120 Broadway, New York, N. Y.
Wills Maclachlan, L. F. Morehouse, C. A. Terry, H. B. Smith.

HEADQUARTERS COMMITTEE

Wm. A. Del Mar, Chairman, Habirshaw Electric Cable Co., Yonkers, N. Y.
F. L. Hutchinson, Charles Robbins.

COMMITTEE ON SAFETY CODES

Farley Osgood, Chairman, 80 Park Place, Newark, N. J.
H. C. Cushing, H. O. Lacount, H. N. Muller, J. C. Forsyth, Johnston Livingston, H. R. Sargent, H. B. Gear, M. G. Lloyd, A. M. Schoen, W. B. Hartshorne, Wills Maclachlan, H. S. Warren, R. W. E. Moore.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

George F. Sever, Chairman, 4 Divinity Ave., Cambridge, Mass.
C. A. Adams, A. H. Babcock, Schuyler S. Wheeler, L. B. Stillwell.

U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 111 Fifth Ave., New York, N. Y.
F. B. Crocker, Vice-President,
James Burke, Vice-President,
A. E. Kennelly, Secretary, Harvard University, Cambridge, Mass.
C. A. Adams, W. C. Fish, Charles Robbins, P. G. Agnew, H. W. Fisher, E. B. Rosa, B. A. Behrend, H. M. Hobart, D. B. Rushmore, J. J. Carty, D. C. Jackson, C. F. Scott, L. W. Chubb, B. G. Lamme, C. H. Sharp, C. L. Collens, 2d, W. S. Moody, C. E. Skinner, W. A. Del Mar, A. H. Moore, S. W. Stratton, A. L. Doremus, R. W. E. Moore, Elihu Thomson, Gano Dunn, L. F. Morehouse, R. B. Williamson, L. T. Robinson.

STANDARDS COMMITTEE

Dugald C. Jackson, Chairman, 387 Washington St., Boston, Mass.
G. A. Anderegg, Percy E. Hart, L. F. Morehouse, Frederick Bedell, H. M. Hobart, F. D. Newbury, B. A. Behrend, H. H. Humphrey, H. S. Osborne, L. F. Blume, P. Junkersfeld, S. G. Rhodes, G. A. Burnham, A. E. Kennelly, Charles Robbins, P. H. Chase, G. L. Knight, L. T. Robinson, E. J. Cheney, F. A. Laws, R. F. Schuchardt, L. W. Chubb, C. O. Mailloux, C. E. Skinner, F. P. Cox, C. S. McDowell, A. B. Smith, E. B. Craft, W. L. Merrill, John B. Taylor, Wm. A. Del Mar, J. Franklin Meyer, A. H. Timmerman, F. M. Farmer, Taliaferro Milton, Philip Torchio, H. W. Fisher, R. W. E. Moore, W. K. Vanderpoel, F. C. Hanker, R. B. Williamson,

EDISON MEDAL COMMITTEE

Appointed by the President for term of five years

(Term expires July 31, 1921.)
W. C. L. Eglin, Bancroft Gherardi, E. W. Rice, Jr.

(Term expires July 31, 1922.)
Comfort A. Adams, Chairman, L. A. Ferguson, S. W. Stratton.

(Term expires July 31, 1923.)
Frederick Bedell, L. T. Robinson, Calvert Townley.

(Term expires July 31, 1924.)
E. D. Adams, H. H. Barnes, Jr. B. G. Lamme.

(Term expires July 31, 1925.)
H. M. Byllesby, D. E. Drake, W. L. R. Emmet.

Elected by the Board of Directors from its own membership for term of two years.

(Term expires July 31, 1921.)
G. Faccioli, W. A. Hall, Wilfred Sykes.

(Term expires July 31, 1922.)
L. E. Imlay, F. D. Newbury, W. I. Slichter.

Ex-Officio

A. W. Berresford, President, George A. Hamilton, Treasurer, F. L. Hutchinson, Secretary.

SPECIAL COMMITTEES

GEOGRAPHICAL DIVISIONS AND ELECTION PROCEDURE

H. H. Barnes, Jr., Chairman, 120 Broadway, New York, N. Y.
Wills Maclachlan, L. F. Morehouse, Paul Spencer,
F. L. Hutchinson,

SUPER-POWER SYSTEM

W. S. Murray, Chairman, 709 Sixth Ave., New York, N. Y.
H. V. Bozell, Malcolm MacLaren, D. B. Rushmore
H. W. Buck, William McClellan, Charles F. Scott
J. W. Lieb, C. S. Ruffner, Percy H. Thomas

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

Philip Torchio, Chairman, 124 E. 15th St., New York, N. Y.

Measurement of Relative Eddy Current Losses in Stranded Cables

BY JAMES A. COOK
The New York Edison Company.

THE amount of energy dissipated by eddy currents in copper conductors is a matter of interest in many branches of the electrical industry. Eddy current losses in stranded copper cables constitute a source of heat. If the alternating flux density is high at usual operating frequencies, the eddy current losses may seriously restrict the conductor rating based on permissible temperature rise. This paper has been prepared, therefore, to describe a method which will provide accurate measurements of eddy current losses on a comparative basis. The method of test is not advanced as being original with the author, but represents the accumulated experience of the Test Department of The New York Edison Company with several series of tests of this character.

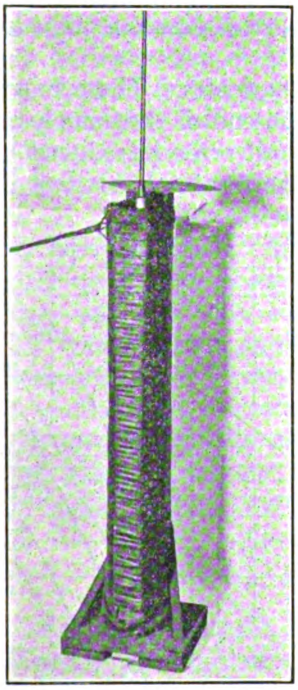

FIG. 1—FIELD WINDING FOR MEASURING RELATIVE EDDY CURRENT LOSSES IN STRANDED CABLE

To be presented at the 9th Midwinter Convention of the A. I. E. E., Feb. 16-18, 1921.

Investigations have been made at various times to determine the effectiveness of various expedients for reducing such losses. These include, for example, (1) impregnating bare cables with varnishes and compounds to insulate the strands from each other, and (2) insulating layers of strands from each other by wrapping the layers with asbestos tape during manufacture of the cable. The relative eddy current loss was determined for the bare and insulated condition; other factors held constant.

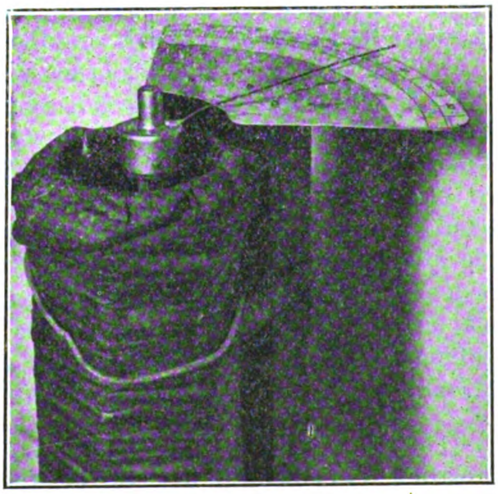

FIG. 2—SUSPENSION OF CABLE SAMPLE IN FIELD, SHOWING BIFILAR SUSPENSION AND SCALE FOR MEASURING DEFLECTIONS

Fig. 1 shows an air-core coil wound with three phases to produce a rotating field. The coils are on a five-inch fiber tube 36 inches long. The winding is full pitch, two-pole, each phase consisting of 100 turns of No. 22 A. W. G. insulated copper wire.

A two-foot length of cable to be tested is hung in the center of the coil by a bifilar suspension as shown in Figs. 2 and 3. Care is taken in cutting the sample not to disturb the lay of the strands. A pointer was mounted as shown in the illustrations to indicate the angular deflection of the cable from the free position.

Balanced field currents were then applied. The

rotating field so produced set up eddy currents in the stranded cable sample, resulting in torque and rotation of the sample until balanced by the torque of the suspension. The angle of deflection is a measure of the torque which can be determined from the dimensions of the suspension as follows:

l = length of suspension threads in cm.
d = distance between centers of suspension threads in cm.
m = mass of sample and suspension cap in gm.
g = acceleration due to gravity = 980 cm-sec.[2]
θ = angle of deflection in degrees.
t = torque due to eddy currents.

$$t = \frac{m\,g\,d^2}{4\,l} \sin\theta \text{ dyne-cm. approximately} \quad (1)$$

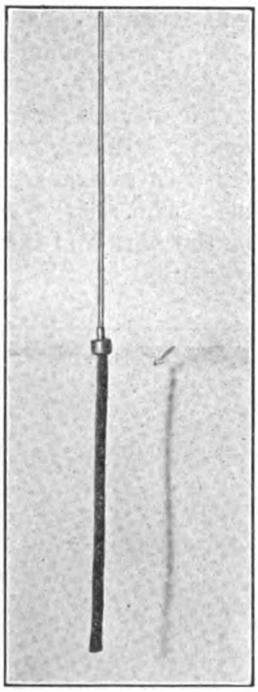

Fig. 3—Method of Attaching Cable Sample to Bifilar Suspension

This relation is substantially correct for small deflections. If $l = 100$ cm., $d = 2$ cm. and $\theta = 30$ degrees, the error introduced by using the approximate formula is less than 1 per cent. In the actual tests described below, the error from using this approximate formula is less than in this assumed case.

With the torque determined, the watt loss by eddy currents p may be computed from the known speed of the rotating field.

$$p = 2\,\pi\,f\,t\,(10)^{-7} \text{ watts.} \quad (2)$$

This use of a bifilar suspension assumes that there is no torsional moment in the suspension and for this reason silk threads are preferable to wire in constructing the suspension.

All cable samples were bound at each end and in the center before being cut from the piece. This was done to keep the strands as nearly as possible in their normal condition. The lashings were not disturbed during the test.

At the ends of the sample where cut, there was a slight burring of the strand ends which had an appreci-

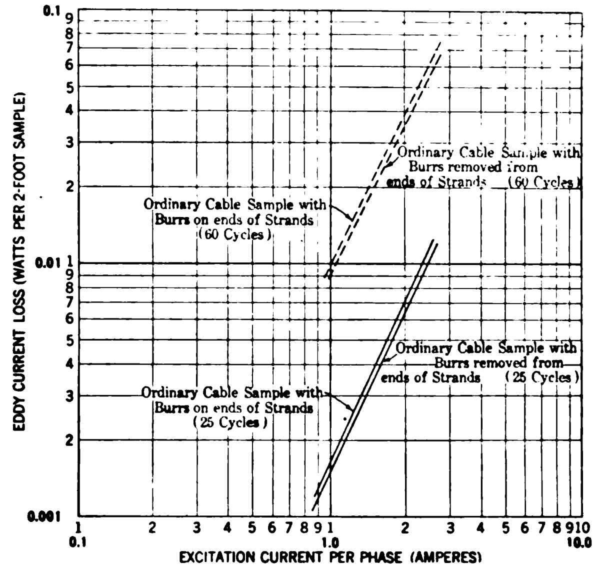

Fig. 4—Eddy Current Losses in Copper Cables
650,000-circular mil—37-strand cable

able effect on the losses. These burrs were removed by immersing the end of the sample in sulphuric acid and the amount of error introduced by the burr was determined. The result of this test is shown in Fig.

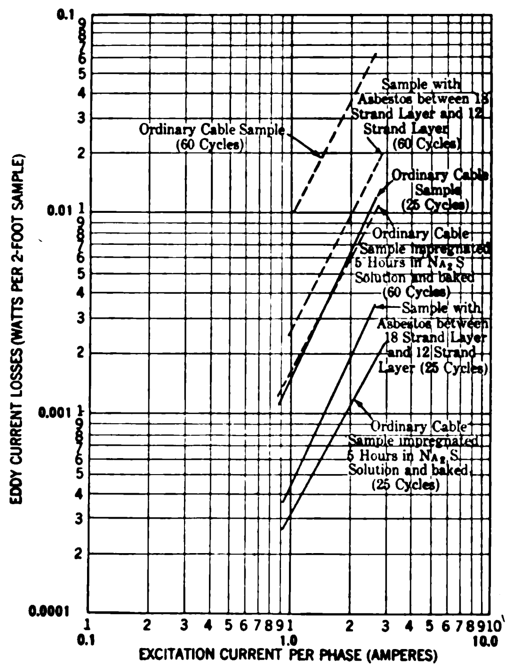

Fig. 5—Eddy Current Losses in Copper Cables
650,000-circular mil—37-strand cable

4. It will be seen that the end effect is comparatively small.

Fig. 5 shows the relative eddy current losses in three samples of 650,000-circular mil, 37-strand cable.

TABLE I—EDDY CURRENT LOSSES IN WATTS FOR TWO-FOOT CABLE SAMPLE.
650,000-Circular Mil Cable 37 Strands
Excitation Current 2 Amperes In Each Test

	As cut from reel		After treating ends with H_2SO_4 to remove burrs		After immersion 5 hours in Na_2S solution and baking one hour at 105 deg. cent.		After bending samples treated with Na_2S solution to arc of circle and straightening			
	25 Cycles	60 Cycles	25Cycles	60 Cycles	25 Cycles	60 Cycles	Radius	No. of times bent	25 Cycles	60 Cycles
Ordinary cable sample........	0.0074	0.041	0.0066	0.037	0.0013	0.0061	14 inches	10	0.0011	0.0061
Cable with asbestos tape between 18-strand layer and 12-strand layer............			0.0020	0.010						

The samples were tested at 25 cycles and at 60 cycles after preparation as follows:

1. Sample cut from cable (no asbestos) and burrs removed from ends with sulphuric acid.
2. Same as in (1) except that the sample was also immersed for five hours in a sodium sulphide solution and then baked one hour at 105 deg. cent.
3. Same as in (1) except that sample was cut from a cable having asbestos tape separating the 18-strand layer from the 12-strand layer.

Reference to Fig. 5 shows the eddy current losses are very considerably decreased from normal by use of asbestos tape between the eighteen-strand layer and the twelve-strand layer. A greater reduction is effected by taking the bare cable and impregnating it with sulphide solution followed by baking. The effect of this impregnation is to form an insulating film of copper sulphide on the individual strands, thus reducing the eddy current losses. An examination of the samples after treatment showed thorough impregnation of the cable by the solution. The individual strands had copper sulphide coating of uniform thickness and at only very few points was the bare copper visible, thus indicating that adjacent strands had been in exceptionally close contact. To determine if the sulphide coating would withstand bending of the cable, strands were bent until the sulphide coating cracked off. It was necessary to bend to a radius of one or two inches before this resulted. The sulphide solution selected consisted of a 10 per cent solution by weight of sodium sulphide. To every 100 parts of this solution, 5 parts by volume of sulphuric acid (specific gravity 1.20) were added.

Samples of cable were bent to arcs of circles of 14-in. and 18-in. radii respectively, and were then straightened and eddy current loss again measured. One sample was bent to a radius of 14 in. ten times in succession. In this instance the losses were smaller than after one bending. This was probably due to the fact that the strands in the cable started to bulge and consequently were in less intimate contact. Table I gives the comparative results of the series of tests made under the conditions described above with excitation of two amperes per phase in all tests.

Sources of error to be avoided are:

1. Burring of cable strands in cutting sample.
2. Failure to suspend the samples in center of field.
3. Disturbance of strands of sample from their normal position, by bending or careless handling.

With suitable precautions, the results of the tests with apparatus described herein are correct within 5 per cent and serve to demonstrate the effectiveness of the various methods of treating stranded cable to reduce eddy current losses.

SAVING PREVENTS ACCIDENTS IN INDUSTRY

Saving and the practise of thrift have always been advocated as a means of obtaining a nest-egg for the future. It has recently been suggested that saving is one of the best preventives of accidents.

This was the opinion of safety engineers and experts at the Industrial Safety Congress, held in Syracuse recently. Many experts held the view that when a man is not worried about financial or other matters, he can concentrate more fully on his job.

Safety engineers and experts in industrial problems present at the Safety Congress were of the belief that a large percentage of industrial accidents could be charged directly to carelessness, superinduced by domestic troubles as generally of a financial nature. They stated that where workers save their money and are financially secure, they are more attentive to their work, more careful about what they do and therefore help greatly in preventing industrial accidents.

The United States Treasury Savings movement aims at encouraging the spirit of saving and in issuing its securities in popular denominations, places them within easy reach of everyone in this country and thus promotes financial security. An individual savings fund means better housing conditions for workmen, insuring better health, steadier nerves, better food, better clothing and a reserve for timely medical attention. It enables them to get ahead, which means greater hopefulness reflected in greater production.

Employers have stated that by forming Government Savings Associations in industrial establishments the Treasury Department is performing an invaluable service which, strangely enough, has the result indirectly of helping decrease the number of accidents to workmen.

Permissible Operating Temperatures of Impregnated Paper Insulation in which Dielectric Stress is Low

BY PHILIP TORCHIO

Chief Electrical Engineer, New York Edison Co.

The writer reviews the effect of temperature on insulating materials, abstracting from the 1913 *Steinmetz and Lamme report, and the 1905 British Engineering Standards Committee tests. Then he gives surveys of low-tension cables in large distributing systems, and special tests on cables including sheath cracking, high temperature tests, effect of bending on cables heated at high temperatures, distillation of cable compounds, ambient temperatures in subway ducts as affected by thermal conductivity of concrete, amount of moisture in soil, different arrangements of ducts and load factors at which the cables are operated.*

From this review, conclusions are derived that the permissible operating temperatures are to be a function of the load factors at which the cables operate. The writer recommends 105 *deg. cent.,* 95 *deg. cent. and* 90 *deg. cent. for load factors of* 33 *per cent,* 50 *per cent, and over* 66 *per cent, respectively.*

A LARGE amount of study has been given in the last seven years to the limiting temperatures of high-tension cables and the attendant dielectric losses. (For details, refer to A. I. E. E. TRANS., Vol. XXXVI—1917, p. 417-527). As these losses begin to increase sharply for voltages higher than 5000 volts around 70 deg. cent., for paper impregnated with vegetable compounds, and 80 deg. cent. for paper impregnated with mineral compounds, an arbitrary limit of "85 deg. cent. minus E in thousand volts" was adopted in the Standardization Rules. With the preponderant feature of dielectric losses in mind, very little consideration was given to low-tension cables per se, so that the arbitrary constant in "85 deg. cent. minus E" became 85 deg. cent. for low-tension cables. It is the object of this paper to deal more intimately with low-tension cables and to present results of extensive investigations and special tests, together with a review of the results of long years of practise.

1. EFFECT OF TEMPERATURE ON INSULATING MATERIALS

In approaching the subject, it may be opportune to quote from the paper of Steinmetz and Lamme of 1913:

> Paper insulation will have a comparatively long life even at ultimate temperatures as high as 100 deg. cent. * * *. At materially higher temperatures than 100 deg. cent. the life is greatly shortened, and temperatures of 125 deg. cent. will apparently ruin the insulation, from the mechanical standpoint, in possibly a few weeks, *if such temperature is maintained steadily.* However, for low voltages, insulating qualities may still be very satisfactory even at this temperature (125 deg. cent.) * * *.

The 1913 paper of Steinmetz and Lamme had been written to present general information on behavior of different insulating materials used in construction of electrical apparatus and to furnish a basis for work of the A. I. E. E. Standards Committee, which culminated in the promulgation of the Standardization Rules in 1916. It is of assistance to us in discussing the problem to refer to these rules for the class of materials under which impregnated paper is classed, *i. e.*, Class A insulation. The limiting temperature allowed by the Rules for Class A insulation is 105 deg. cent. *continuous*.

2. BRITISH STANDARDS ENGINEERING COMMITTEE

It may be of interest here to reproduce results of careful tests made in 1905 by the Engineering Standards Committee of Great Britain. These tests, at the time the A. I. E. E. Rules were worked out, were probably the most comprehensive study then published. I am selecting from numerous tests on a great number of materials some that more closely approximate the condition of impregnated paper.

The tests were made by subjecting the samples either to continuous temperatures or temperature over periods of twelve hours daily for several months up to nine months or one year. The samples were tested for dielectric strength, shearing and bending. The shearing test was determined by the use of a punch of one-half inch in circumference, and determining the pounds pressure at which the samples broke. The bending tests consisted in taking a strip of the insulation sample and bending it over a series of cylinders of gradually decreasing diameters, note being taken of the cylinder diameter over which the fracture would first occur.

A number of curves showing the results of the shearing and bending tests of various samples of insulation are presented. In either case, the *total number of hours, with the heat on,* was computed, omitting the hours when the heat was off, so that the abscissas represent the *equivalent weeks of continuous heating.*

For the object of comparison, instead of giving the pounds test pressures for each sample, the shearing tests are plotted in per cent of the shearing strength of the unheated sample, taken as 100 per cent. The shearing curves in Figs. 1 and 2 have been interpolated from results of two separate investigations on similar samples of Manila paper, extending approximately 9 and 30 weeks, while the shearing curves in Figs. 3 to 6 were obtained from tests taken at 12 periods throughout an interval equivalent to 26 weeks' continuous heating.

To be presented at the 9th Midwinter Convention of the A. I. E. E., Feb. 16-18, 1921.

The bending curves in Figs. 7 to 14 are interpolated from the results of three separate investigations on similar samples extending 4, 9, and 30 weeks, respectively. The ordinates of these curves represent the minimum diameter of cylinders over which the samples can be bent without fracture, and they are interpolated for 75, 100, and 125 degrees heating.

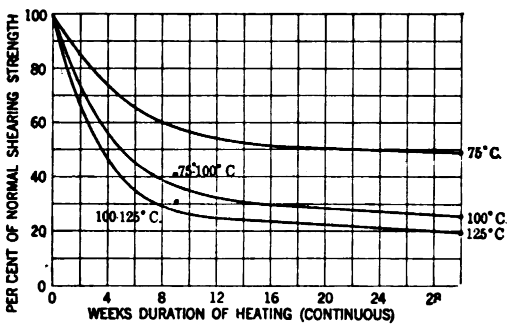

Fig. 1—Manila Paper—0.012 in. (0.3 mm.)

The *bending curves* for various materials *cannot be compared directly* as the bending test is a function of the insulation thickness which varies in each case.

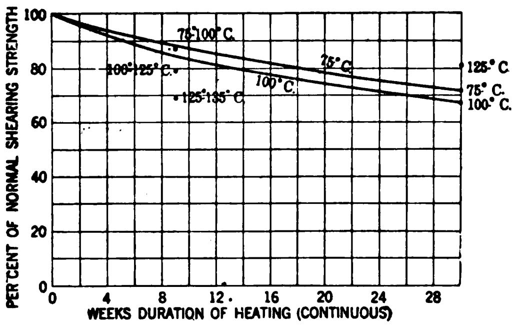

Fig. 2—Manila Paper Varnished—0.014 in. (0.355 mm.)

However, they are of interest to show the bending qualities of each sample as compared to its original unheated condition. In many cases, a $\frac{1}{16}$-inch cylinder

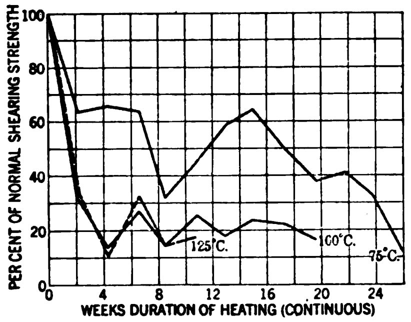

Fig. 3—Empire Cloth—0.040 in. (1.016 mm.)

is shown as a minimum and most samples could be bent in the unheated state ten or more times over this cylinder without injury. For the large diameters, however, the curves represent a single bending.

Fig. 1 gives the shearing tests on a sample of untreated Manila paper of 12-mil thickness. The shearing strength of the heated samples has been greatly reduced at the end of the 30th week over the unheated sample; the percentages being 49, 25, and 19 for the

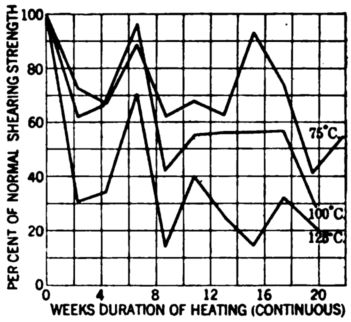

Fig. 4—Calico Impregnated with Elastic Insulating Varnish—0.016 in. (0.406 mm.)

75, 100, and 125-deg. cent. heating, respectively. Corresponding to the shearing curves in Fig. 1 are shown the bending curves of Manila paper in Fig. 7. The

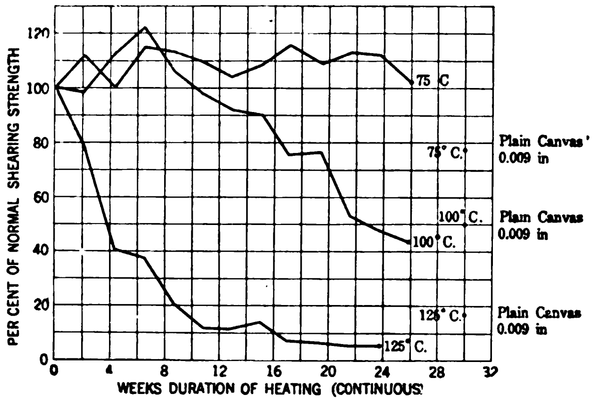

Fig. 5—I. R. Prepared Duck—0.027 in. (0.686 mm.)

unheated sample could be bent over a $\frac{1}{16}$-inch cylinder ten or more times without injury. After being heated for 30 weeks, the sample could only be bent around

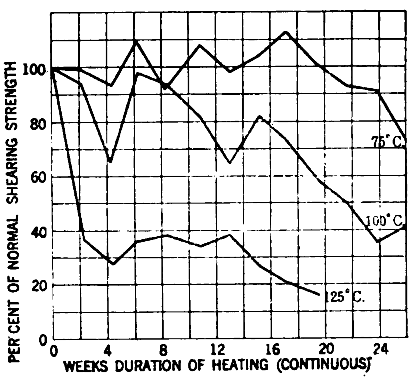

Fig. 6—Press-Spahn—0.040 in. (1.016 mm.)

cylinders of ¼-, 1½- and 2-inch diameters for the 75, 100, and 125-deg. heating, respectively.

Fig. 2 gives the shearing tests of a sample of varnished Manila paper of 14-mil thickness. (Only the 75 and

100-deg. cent. curves have been drawn as the 125-deg. points seemed somewhat irregular. The values are, however, the average of several tests taken on different part of each specimen.) After being heated for 30 weeks at 75, 100, and 125 deg. cent., these varnished Manila paper samples had values of shearing strength

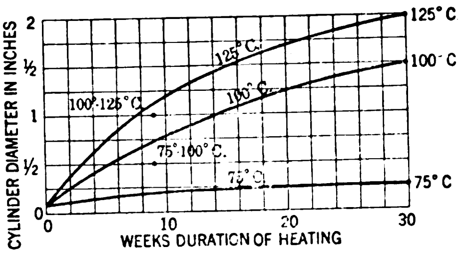

Fig. 7—Plain Manila Paper—0.011 in. (0.23 mm.)

equal to 71, 68, and 81 per cent respectively, of the unheated sample. Their shearing strength is, therefore, retained to a much greater extent than in the untreated Manila paper samples.

Corresponding to the shearing curves for varnished Manila paper shown in Fig. 2 are the bending curves shown in Fig. 8. The unheated sample could be bent

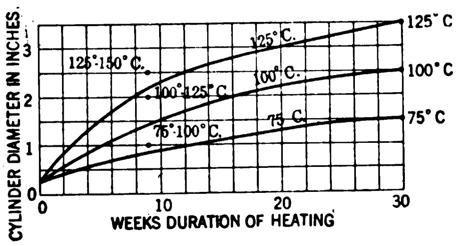

Fig. 8—Manila Paper, Varnished—0.014 in. (0.355 mm.)

around a ¼-inch cylinder without injury, while the samples heated at 75, 100, and 125 deg. cent for 30 weeks could only be bent around cylinders of 1½-, 2½- and 3½-inch diameters, respectively.

Only rough bending tests were taken on samples whose shearing curves are shown in Figs. 3 to 6.

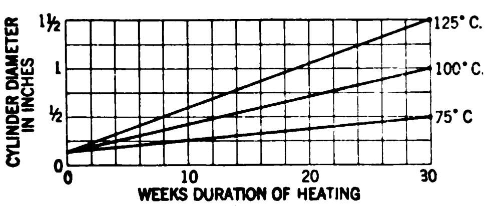

Fig. 9—Canvas Varnished—0.0157 in. (0.40 mm.)

They were bent to and fro, and note taken as to whether they cracked or broke.

Fig. 3 gives the shearing tests for empire cloth. The sample was destroyed at the end of the 20th week at 100 deg. cent., while the sample heated at 125 deg. cent. was destroyed at the end of the 11th week.

Fig. 4 gives the shearing tests for a sample of calico impregnated with elastic insulating varnish. The 75-degree sample broke on bending at the 20th week; the 100-degree sample at the 4th week; and the 125-degree sample at the 2nd week.

Fig. 5 gives the shearing tests for a sample of I. R. prepared duck (reinforced rubber). The 75-degree sample was practically unaltered at the end of the

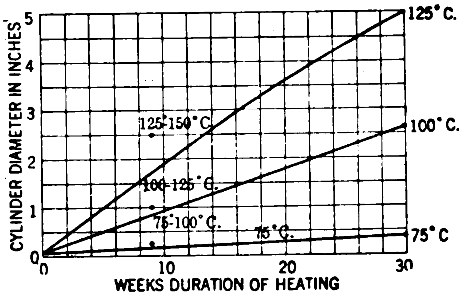

Fig. 10—Berrite Fabric—0.013 in. (0.33 mm.)

26th week. The 100-degree sample showed only 43 per cent of its shearing strength for the same time, while the 125-degree sample broke on bending at the end of the 24th week. (On the same figure are shown the shearing values of untreated canvas of 9-mil thickness, heated at 75, 100, and 125 deg. cent. for 30 weeks).

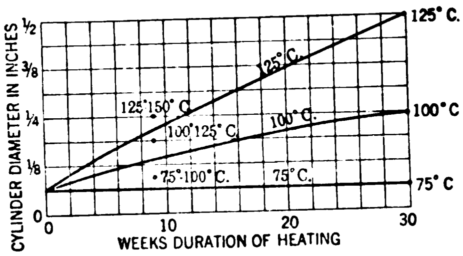

Fig. 11—Excelsior Linen—0.0063 in. (0.16 mm.)

Fig. 6 gives the shearing tests for a sample of press-spahn. The 75-degree sample cracked on bending at the 26th week, but was practically unaltered up to the 22nd week. The 100-degree sample cracked on bending at the 20th week, while the 125-degree sample broke on bending at the end of the 2nd week.

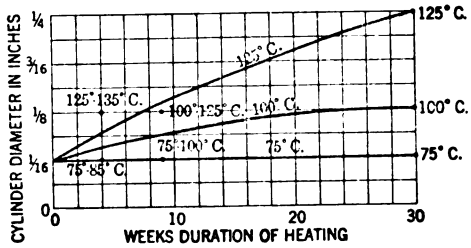

Fig. 12—Excelsior Paper—0.0047 in. (0.12 mm.)

Bending tests of other samples of insulation, such as varnished canvas, Berrite fabric, press-spahn, and oiled cloth, are shown in Figs. 9 to 14 inclusive.

In general, treated Manila paper compares very favorably in shearing strength with other types of vegetable fibrous insulation, and it also has the same

general bending characteristics. Varnished Manila paper of 14-mil thickness, at the end of 30 weeks' heating at 100 deg. cent., still had a shearing strength of 68 per cent of the unheated sample, and could be bent around a cylinder of 2½-inch diameter, while the same temperature destroyed a sample of empire cloth at the 14th week, of I. R. prepared calico and press-spahn at the end of the 16th week, and of varnished calico at the end of the 18th week.

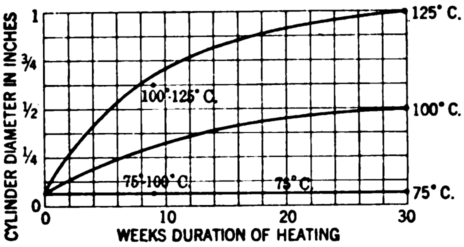

FIG. 13—PRESS-SPAHN—0.010 IN. (0.25 MM.)

In practically all samples, *the dielectric strength showed but small deterioration until mechanically destroyed.*

3. APPLICATION TO CABLES

Having before us these results of different insulating materials, we may review their limitation to specific uses by applying our engineering judgment. It is, of course, difficult to make an exact comparison of the conditions under which insulating materials are to operate in the great variety of apparatus to which they are applied.

However, we may start from the point that impregnated paper, under the A. I. E. E. Standardization Rules as Class A insulation, is good for 105 deg. cent. continuous. It is not here the case of discussing whether this limit is too high or not. Personally,

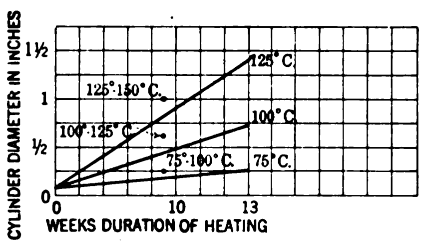

FIG. 14—OILED CLOTH—0.0087 IN. (0.22 MM.)

after studying similar data as given in the British Committee tests, from which I have abstracted the few illustrations in the foregoing paragraphs, I feel that 105 deg. cent. is too high if applied continuously; but to this I shall make reference later. For the present, we may assume that impregnated paper as Class A insulation should withstand safely 105 deg. cent. If such is the case, what consideration would prevail to modify this limit on account of the possible different conditions that might exist in cables versus other electrical apparatus like armature coils, et cetera?

3A. REASONS ADVANCED FOR LOW TEMPERATURE LIMITS

The principal reasons advanced for adopting lower temperature limits than 105 degrees cent. for cables have been two:

1. That the compound in the cable, when warm, may leave the paper, especially when the cable is installed in inclined ducts, with a tendency to flood the lower portion of the cable and to leave the upper part of the cable dry.

2. That cables are oftentimes removed from subways for reinstallation in other locations and, therefore, if the paper becomes brittle, it would crack inside the lead sheath.

Another reason for advocating the lower temperatures is that the expansion and contraction of long lengths of *large size lead-covered cables* may cause cracking of the lead sheath at sharp bends in manholes.

3B. THE RELATION OF TEMPERATURE LIMIT TO LOAD FACTOR

It is now my purpose to present data to prove that these reasons are insufficient to make an exception to the Standards Rules for Class A insulation for 105 deg. cent. for low-tension cables; but before presenting these facts, I want to emphasize the point that while in machinery the 105-degree allowable limit is reached for long periods of time of operation of the apparatus, on the other hand, *low-tension cables, as usually used in large distributing systems, are not subjected to the maximum temperature except for short periods of time each day,* so that in such cases the 105 *deg. cent. for the low-tension cables is immeasurably safer* than the 105 *deg. cent. for machinery,* which may operate at that temperature continuously or at least for periods of eight or ten hours each day. Anticipating my conclusion, I will broadly state that the *limiting temperature* should be a *function of the load factor* (*average load to yearly maximum*) under which the apparatus is to operate, so that *if the apparatus, either cable or machinery, is to operate for long hours at full load, the limiting temperature should not exceed say* 90 *deg. cent.,* while on the other hand, *if the cable or machinery is to operate for a short number of hours* at heavy load and then be subjected to a long period of cooling, as occurs on cables in large systems of distribution, the limiting temperature for the peak loads should be raised, and the 105 deg. cent. limit should be standardized.

4. SURVEYS AND TESTS

I herewith submit conclusive evidence of the fact that 100 deg. cent. to 110 deg. cent. are safe and standard in practise in large subway and distributing systems. The evidence consists of (1) results from observations obtained by wide and close scrutiny of the physical and electrical conditions of all the low-tension cables of a large electric power company, The New York

Edison Company; and (2) results of special tests carried out by engineers and laboratory men.

4A. Field Surveys

Investigations of a very thorough and exhaustive character were prompted by three occurrences, unprecedented in the history of the company, of serious short circuits of low-tension cable feeders. These occurrences were at first unexplainable and therefore were highly perplexing to the managers and engineers. The coincidence of these disturbances at the period of the winter of 1919 when the company was called upon to furnish an unprecedentedly and unexpectedly heavy increase in power demand, causing the low-tension cables to carry heavier loads than customary in any previous year, naturally led one to suspect that the cable insulation might have been damaged.

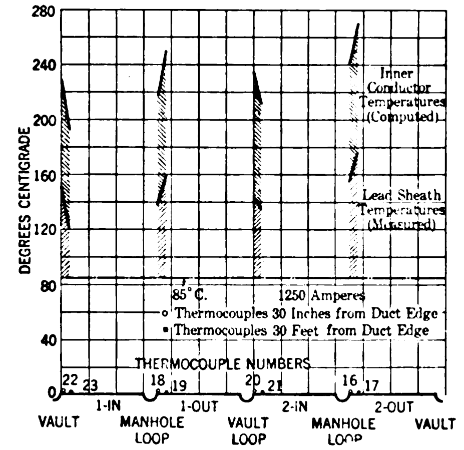

Fig. 15—Maximum Temperatures—Cable Sheath Cracking Test

The results of the physical inspection of all cables showed that a number of 1,000,000-cir. mil concentric feeder cables, not necessarily carrying heaviest loads, but in congested banks of ducts, had their sheaths cracked near the edge of the ducts and at sharp bends in manholes where the movement of the cables, due to expansion and contraction, was impeded. These cracks extended to the insulation, leaving an open path for moisture and water to reach the copper and to cause a local short circuit, which would endanger the neighboring cables and cause manhole explosions. It is not here the place to enter into a description of ways and means developed to securely protect the system from these dangers of low-tension cable short circuits, but what is of vital interest is the fact that *not a foot of cable was found with impaired insulation* outside the point of the crack or burn-out at the short circuit. That is, that cable a few feet from the burn-out, and all the rest of its length, was thoroughly sound and undamaged.

4B. Sheath Cracking and High-Temperature Tests

One of the numerous special tests carried out in the comprehensive study of the subject throws additional light on the findings of the physical inspection of all the cables on the system. We made a series of tests on four 278-ft. lengths of cables installed in ducts between manholes connected in series, with bends and splices to simulate actual conditions. The object was to determine loads, temperatures, and expansion of cables at which the sheaths would crack if the cables were submitted to specified cycles of eight-hour load and sixteen-hour no-load for periods of weeks, extending over two months. Temperatures of sheaths were taken by thermocouples and the inner copper temperatures calculated, using the Atkinson constant of thermal resistivity of 354, which we have independently checked and which seems to be approximately correct. Fig. 15 gives the maximum temperatures for lead sheath and inner copper for the different thermocouple locations at a 1250-ampere run. Figs. 16, 17 and 18 give characteristic runs at 800, 1000, and 1250 amperes continuous load for eight hours. Inner copper temperatures at location of thermocouple No. 20 for the full period of test are graphically represented in Fig. 19. From the diagram, it appears that the insulation at the point "thermocouple No. 20" withstood the following temperatures:

Inner Conductor Temperature (Degrees C.)	Hours	Remarks
Less than 85	73	Hours of tests with current on —exclusive of hours of cooling with current off.
85—90	13	
90—100	26	
100—110	37	
110—125	88	
125—150	36	
Over 150	169	
Total duration of test periods	442	

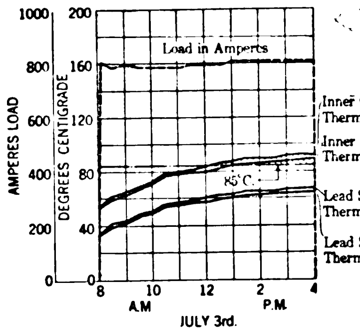

Fig. 16—Cable Sheath Cracking Test
800-Ampere d-c. run

The sample of cable at location "thermocouple No. 20" showed its insulation in good condition, the inner insulation being darkened and of considerably reduced tensile strength, but yet in perfect condition

for indefinite service, notwithstanding the fact that the insulation operated at over 110 deg. cent. for 293 hours; temperature of over 125 deg. for 205 hours; and temperature of over 150 deg. for 169 hours.

At other locations, the maximum temperature exceeded the temperature noted for location "thermocouple No. 20." (See Figs. 15 and 18). At thermo-

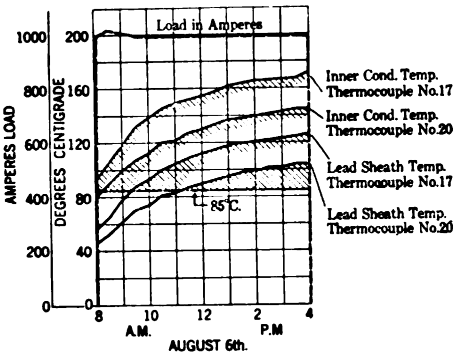

Fig. 17—Cable Sheath Cracking Test
1000-Ampere d-c. run

couple No. 17, the copper temperature reached a maximum of 269 deg. cent., and temperature in excess of 240 deg. cent. existed for 4½ hours.

4c. Effect of Bending

With these enormously high temperatures, only 20 feet of one length, out of the 1112 feet of cable, had their insulation destroyed. The four lengths were

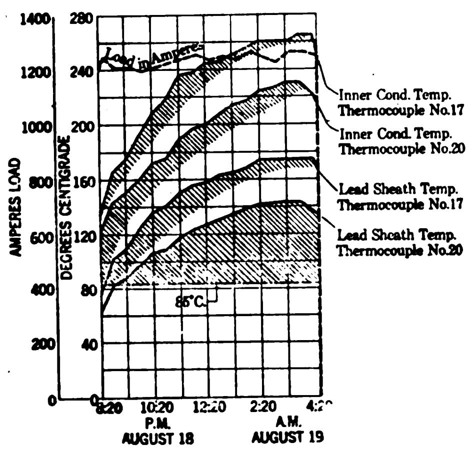

Fig. 18—Cable Sheath Cracking Test
1250-Ampere d-c. run

removed from the ducts and reeled, and re-reeled in some instances twice, and after this handling the cable lengths were subjected to regular factory voltage and insulation tests, with the following results:

		Voltage Tests 5-minute application		Insulation Test megohms per mile	
Section	No. of times re-reeled	Inner to outer and lead	Outer to inner and lead	Inner to outer and lead	Outer to inner and lead
1 in	1	5400	5900	460	184
1 out	2	5400	*	770	...
		5500	5700	703	289
2 in	1	5500	6600	100	56
2 out	2	5400	5800	520	105

*Broke down 12 feet from the end near hub of reel after two minutes at 6000 volts. Balance portion retested with results in second line "1 out."

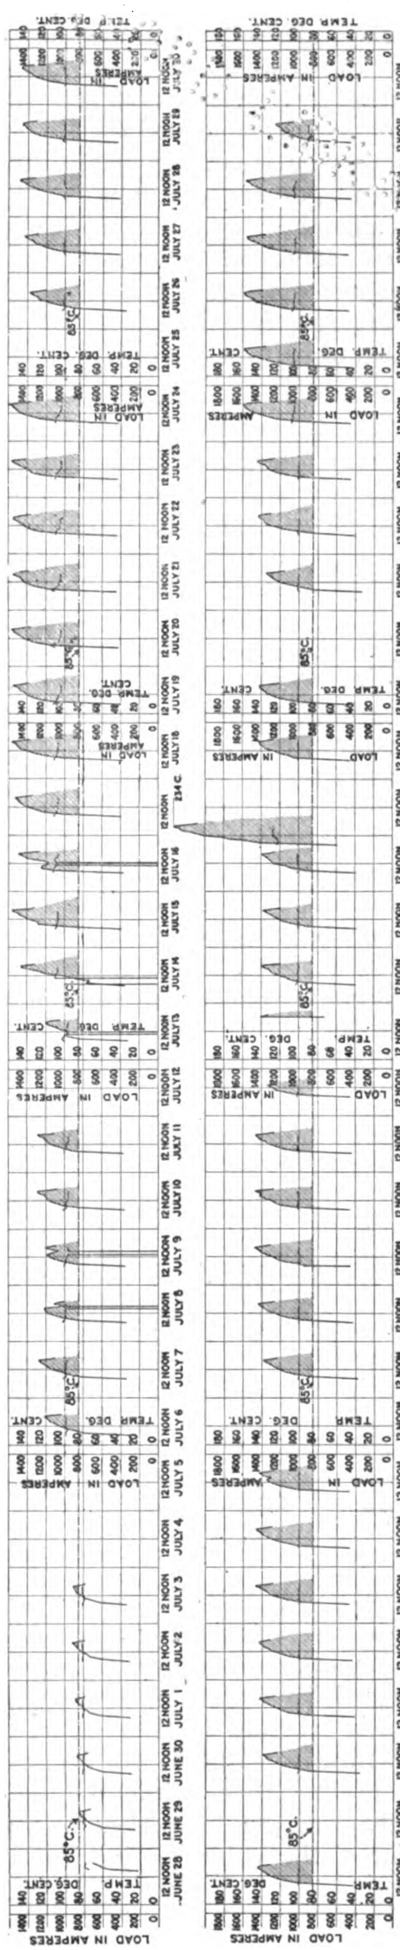

Fig. 19—Inner Copper Temperatures at Location of Thermocouple No. 20 for Period of Test

Apparently even after the withdrawing and rehandling of this cable, which had been subjected to such high temperatures, in excess of 200 deg. cent., over 98 per cent of the cable was still in such fair condition that it would have been reinstalled, if the lot had come from ordinary withdrawals. The insulation of this cable that, at thermocouple No. 20, withstood for 169 hours temperatures of over 150 deg. cent., must have been immeasurably more affected than if the temperature had been limited to 105 deg. cent. for a great number of years of service during the winter

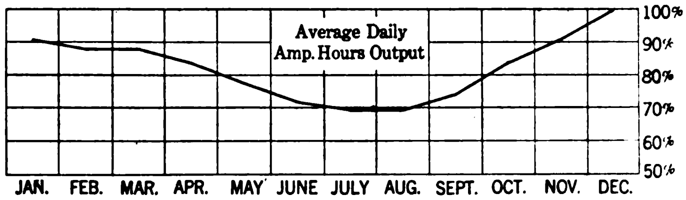

FIG. 20

peaks as prevailing on large systems of distribution· (Time does not permit of figuring out the total hours of high, average, and minimum temperatures engendered by the characteristic load curves for different seasons of the year; but for any one interested in the subject, I attach diagrams of average daily output throughout the year, and characteristic load diagrams for each season of the year, as per Figs. 20 and 21). The point that may be made here is that the operation of a cable at 105 deg. cent., in ordinary systems of distribution, will not prevent the cable from being removed and reinstalled without injury.

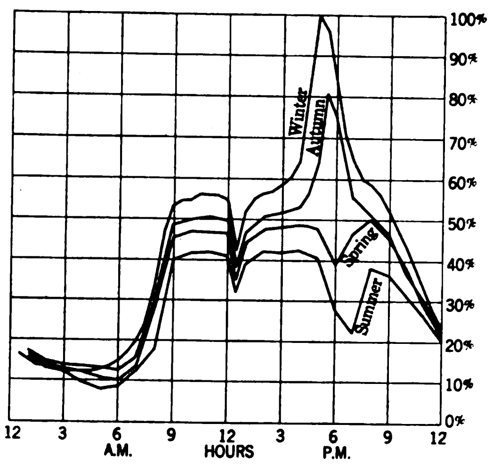

FIG. 21

4D. OTHER COMPANIES' EXPERIENCE

The experience of several large companies, like The New York Edison and Commonwealth Edison Company of Chicago, who have operated for the last twenty years a substantial number of their cables at loads producing temperatures of 100 to 110 deg. cent. during the winter peaks, proves without question that these seasonal temperatures for periods of peak loads have not impaired the cable or its insulation for occasional withdrawal and reinstallation any more than on cables of the same age which have never sustained but lower temperature. The hardening of the oil in the insulation which, as we have seen, takes place if temperatures of 100 deg. cent. and over are sustained continuously for periods of several months, will either not take place at temperatures of 105 deg. cent. applied only for short periods for certain seasons of the year; or if any hardening takes place, the process will extend over long periods, exceeding 15 or 20 years. At the ends of these periods, it is improbable that any substantial amount of such cable will still be required for reinstallation, if removed, but if the lead sheath is intact, the tests on the sample cables submitted to almost destructive temperatures have shown that the cable can still be reeled and re-reeled without destroying its efficiency for service both as to dielectric strength or insulation resistance; in practise, the aging and deterioration of the lead sheath, due to chemical action electrolysis, et cetera, will be the *paramount factor in the life of low-tension cables.*

Regarding the question of the compound leaving the insulation, I think it can be dismissed by considering the fact that this migration of compound will only be partial, and whatever remains of the compound with the paper still offers a factor of safety in dielectric strength from ten to twenty-five times the low-tension operating voltage.

The difficulties of lead sheaths cracking in large sized cables are essentially problems of careful installation and handling of the cable. In the sheath cracking test, we have been unable to produce cracking under the extraordinarily severe conditions of temperatures which gave expansions as large as 8 inches in 278 feet. In practise, with 105 deg. cent. temperatures, the expansion would only be 3¼ inches.

5. DISTILLATION TEMPERATURES OF CABLE COMPOUNDS

The question has also been raised that the compound might distil or vaporize at temperatures of above 100 deg. cent. An exhaustive investigation was made by The New York Edison Company to determine the effect of temperature on cable impregnating materials. The results of laboratory tests carried out by the Electrical Testing Laboratories indicated that the mineral compound gave the first drop of distillate at 205 deg. cent. A supplementary investigation was made to determine if the compounds would distil any appreciable amount at temperatures below 200 deg. cent. when exposed to these temperatures for long periods of time. No distillate, however, was obtained for either mineral or resin compounds after being maintained successively at temperatures of 115, 130, 145 and 160 deg. cent. for three days. Similar results were obtained when the temperature was maintained at 180 and 200 deg. cent. for 24 and 36 hours.

To further determine if the increasing temperature produced any gas within the cable, an investigation

was made with a test tube and the temperature raised from 100 to 200 deg. cent., an attempt being made to ignite the vapor above the surface of the compound at the different temperatures. In the case of the mineral compound there was absolutely no tendency to ignite throughout these temperatures. With the resin compound, however, it was found that the passage of a spark at a temperature of 145 deg. cent. caused the vapor to explode, this action continuing up to 160 deg. cent. behind which no further explosions took place as the temperature was raised to 200 deg. cent.

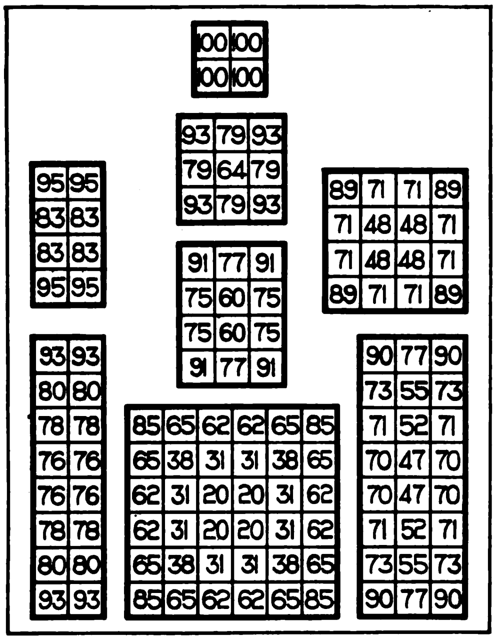

FIG. 22—RELATIVE WATT LOSSES FOR INDIVIDUAL DUCTS AND BANK OF DUCTS PER FOOT OF CABLE FOR SAME TEMPERATURE RISE (PER CENT OF 2 BY 2 BANK)

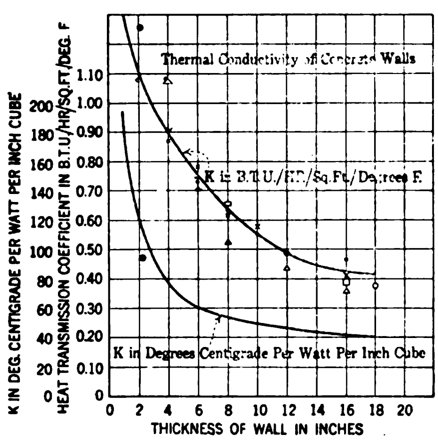

• N.Y. Edison Values

• Mechanical Equipment of Buildings-N.S. Thompson-1915

FIG. 23

These tests conclusively dispose of the possibility of danger from all compounds operated at temperatures below 125 deg. cent.

6. VITAL IMPORTANCE OF AMBIENT TEMPERATURES IN SUBWAY DUCTS

Before making the final recommendations, I wish to bring out a point of importance, that the operator must carefully study the temperatures under which the cables will operate when placed in subway ducts, especially when the trunk lines contain many ducts and cables in one bank.

The paramount importance of carefully surveying the ambient temperature conditions in ducts is shown in Fig. 22 giving the relative allowable losses for a given temperature on each cable with different duct arrangements. In the figure, the losses in a bank of two by two ducts are assumed as 100 per cent.

The actual values of losses allowable per duct-foot will vary greatly according to the load factor, the thickness of the concrete wall surrounding the bank of ducts, and the amount of moisture in the soil. The thermal conductivity of concrete, as obtained by special tests by The New York Edison Company, is shown in Fig. 23, which also represents a compilation of results obtained by other authorities for different thicknesses of concrete. The variation in conductivity with thickness is probably due to the fact that surface drops were also involved.

The thermal conductivity of the soil under various conditions of moisture was determined with the following results:

Dry sand	90	deg. cent. per watt, per inch cube
Natural soil (approximately 6 per cent moisture)	39	
Natural soil with 9 per cent moisture added	19	

7. THE RECOMMENDATIONS FOR TEMPERATURE LIMITS

After having reviewed all of the foregoing data, including the Steinmetz and Lamme report, the British Engineering Standards Committee tests, the surveys of large operating companies, and all special tests and findings herein presented, I submit that the permissible operating temperatures of impregnated paper insulation, in which dielectric stress is low, are to be a function of the load factor at which the cable operates. The load factor for cables used in systems of distribution is intended to be the ratio between the yearly average load and the maximum load on the cable. It is certain that a load factor of say 33 per cent with seasonal winter peaks and correspondingly smaller maximum loads for the rest of the year will produce an average temperature on the cable considerably below 85 deg. cent., so that a limit of say 105 deg. cent. at peaks for 33 per cent load factors is unquestionably safer than 85 deg. cent. continuously, as allowed by the present Institute Rules. The proposed plan corresponds with the well established practise of rating electrical apparatus at a temperature rise of say 40 deg. cent. for continuous loads and from 55 to 65 deg. cent. for two or three hours overload. Machinery so designed has given excellent service for the last 25 years.

I should suggest for consideration for impregnated-paper, low-tension cables the temperature limits in function of the load factor of the cable, as follows:

105 deg. cent. for load factors	around	33 per cent
95 " " " " "	"	50 per cent
90 " " " " "	" over	66 per cent

The suggested temperature limits may perhaps be presented in a more general form by working back from the load factors to corresponding values of rise of temperature allowable for normal loads and overloads for specified hours. I *prefer to use the load factors* as they are fundamental in the determination of the most economical current density in cables as per *the Kelvin law which prescribes lower current density, and consequently lower losses and smaller temperature rise, the greater the load factor.* This gives a balance between economy and heat stress upon insulation. However, the important principle to be established is that the limiting temperature must be lower the greater the number of hours the insulation works at that temperature.

The shortcomings of the present Rules are that for cables they do not allow any rise of temperature for brief overloads above the 85 deg. cent. which is the limit for continuous operation, while they allow, for the same type of insulation in machinery, 105 deg. cent., continuous.

The Limitations of the Stop Watch as a Precision Instrument

BY A. L. ELLIS

Thomson Laboratory, General Electric Company, Lynn, Mass.

IN MANY scientific and engineering measurements the quantity, time, is an important factor. Its value may be required within widely varying limits of accuracy. A high degree of precision can of course be obtained with our present-day astronomical clocks in proper environment and their usefulness greatly extended by electrically relayed circuits. This method, however, is cumbersome, leaves much to be desired and is not generally applicable to laboratory measurements, not to mention the wide variety of field work. The result is, the more convenient stop watch is frequently the criterion used in judging intervals of from a few seconds to periods between appointments with the dentist.

Believing that the characteristics are not generally appreciated by the user, it is the purpose of this paper to point out the limitations of the stop watch in precision measurements. It will not be necessary to discuss such relatively classical adjustments as "isochronal" and "thermal," as errors due to these sources are entirely masked by those due to the principle of operation, mechanical restrictions, and design.

The several types of watches to be discussed will serve to illustrate the sources and character of the errors in those commonly used. Claim is not made that all types are shown nor is it the purpose of this paper to choose among the types.

Applications

A great majority of the stop watches made are sold to the non-technical public who put them to the use of an ordinary timepiece, and occasionally time sporting events. Obviously, they are designed and manufactured to meet the demands of this class of trade. As their use as timekeepers is of first importance, they are made in many grades. To these grades are added the start, stop, and reset mechanism of the sweep second hand, and which in the case of a given make, is the same for all grades. Therefore, the limitations of a given type of stop mechanism of a given make are the same in the low and high-priced watch.

As used by the technical public, the performance as a stop watch is the prime requisite. The accuracy of many scientific and engineering measurements is limited by stop watches' inaccuracies. Designed to meet the needs of the non-technical public, where the stop mechanism is used a few times a year, it is not robust enough to stand up under the demands of engineering tests, as for instance, the calibration of watt-hour meters, where a day's use exceeds several years non-technical use.

Experience of over twenty years in a manufacturing organization, with over four hundred stop watches, (including thirteen makes and nineteen models), shows that nearly all are in the repair shop every two months and in cases where the use is more nearly continuous, as in meter testing, operation tests, etc., the repair shop intervals do not exceed two weeks.

Cost Versus Time Keeping

The ideas of the technical public as to what constitutes the best stop watch vary greatly. Many think the more costly the better. That this view, when applied to a stop watch, is wrong, will be made evident.

One of the big factors of cost of a modern timepiece is the adjustments for running in any position. Essential to these adjustments are the jewels of the train. Where the adjustments are approximate, only a few are required. Where the adjustments are to be pre-

To be presented at the 9th Midwinter Convention of the A. I. E. E., February 16-18, 1921.

cise, many are required and the cost is increased out of proportion. Precise adjustments cannot be made without many jewels and high cost, but it does not necessarily follow that with a large number and high cost one obtains precise adjustments; this idea is common as any jeweler can affirm, and accounts for the catch-penny watches of obscure make upon the market.

The function of the jewels, as you all know, is to reduce friction to a minimum, that the energy imparted to the balance may be the same with each tick, altered

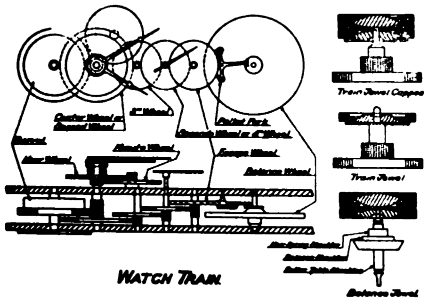

FIG. 1

as little as possible by the variable wear, as time goes on. The disposition of these jewels and their bearing upon the requirements of a stop watch will be considered.

A very important timekeeping requisite is that the balance in its oscillations shall swing unhampered in any way. This requirement is an inherent source of error for a stop watch and will be considered together with the jewels at this point.

Fig. 1 is a diagrammatic sketch showing the disposition of the principal parts to be jeweled. Starting with the wheel marked "barrel" containing the mainspring, the force of which acts through the center or second wheel, the third wheel, the seconds or fourth wheel, the escape wheel, the pallet fork arbor to the balance, the speed of revolution increases in the order named. The force acting upon the bearings to produce friction, however, is greatest at the slowest speed. The disturbance, due to friction and wear, is greatest on the fast moving bearings. The importance of jewels is greatest at the balance and diminishes as the barrel is approached. The practise varies greatly. The most common, and certainly the most important is a seven-jewel movement. These jewels are disposed two at each end of the balance staff, the roller jewel and the two jewels of the pallet engaging the escape wheel. Of the two at each end of the balance staff one acts to center the staff (ring stone), and the other to limit end play (end stone). Their general shape and the staff are shown at *A*. The diameters of the pivots are made as small as possible, in some cases 0.002-in. diameter, to reduce friction. The roller jewel in the roller table is of special shape, varying in different makes.

The next common arrangement is the fifteen-jewel movement obtained by adding ring stones to the bearings of the pallet fork, the escape wheel, the fourth wheel, and the third wheel.

Seventeen jewels are obtained by adding two ring stone jewels to the center wheel.

Nineteen-jewel movement is obtained by adding two jewels to the barrel between the barrel and its staff, or by adding two cap jewels to the end of the escape wheel staff. An additional number of jewels is obtained by adding caps to the remainder of the train.

Fig. 2 gives some of the more important characteristics of the modern escapement showing the escape wheel and its connection with the balance through the pallet and fork.

The escape wheel is shown locked against the pallet stone *R* at position marked "lock." The pressure of the mainspring at this point holds the fork against the upper banking pin.

The roller jewel marked "jewel pin" is shown carried into contact with the fork slot by the balance rotating in a counter-clockwise direction. Some of the energy in the balance wheel will be expended in carrying the fork through an angle of from one to one and a half degrees, the angle of lock, backing up the escape wheel against the mainspring. At this point the impulse face of the escape wheel club comes in contact with the impulse face of the pallet jewel *R* and energy is transferred from the mainspring to the balance carrying the pallet and fork against the lower banking pin, the jewel pin on the balance being released from the slot. The balance then continues free motion until its energy, minus that of friction, is

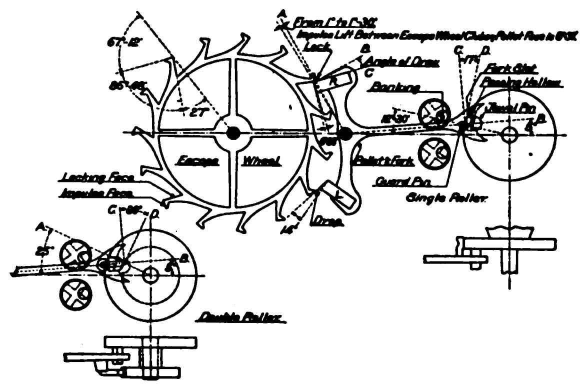

FIG. 2

transferred to the hair spring where the spring reacts to return the balance and the operations are repeated. The balance swings nearly a full revolution to the right and to the left from its position of rest. The actual excursion depends upon the force of the mainspring acting at the escapement, (friction losses in the balance and other moving parts, etc., are neglected). In general, the excursion of the balance is 680 degrees of motion. The roller jewel is in contact with the pallet and fork through 60 degrees of its motion. The pallet fork moves through an angle of ten degrees.

Of this angle, a degree and a half to two degrees are necessary for lock and drop. Through the remainder of the angle the escape wheel, and therefore the train are in motion. The corresponding angle of the balance wheel is from 48 to 51 degrees. From this it will be seen that the train has an intermittent motion, being in motion during the time that the balance swings through its center position at its maximum velocity. The train is in motion while the balance swings through

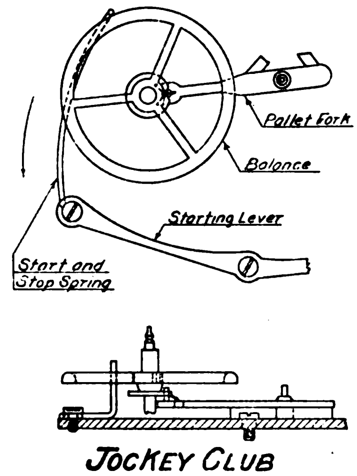

FIG. 3

0.07 of its excursion. The corresponding time is 0.01 of a second, the period of the balance being 0.2 sec. or a frequency of 18,000 beats per hour, 300 beats per minute.

Errors of a Mechanically Perfect Stop Watch

From the foregoing, it will be seen that the sweep second hand of a stop watch is in motion but a small part of the time during an observation. In timing an event the watch may be started just after the escape wheel has been released and stopped, just before the escape wheel is to be again released, in which case the time observed at the sweep second hand would be too short by one beat or $^1/_5$ of a second. The start and stop can also be so timed that the error will be one beat too much. Therefore, two mechanically perfect watches used to time the same event may disagree by $^2/_5$ of a second or 1.3 per cent in a thirty-second reading or both watches can be in error by half this amount plus or minus as the second limit.

Rate

Watches to be adjusted to keep time with extremely small variations must of necessity have many jewels. The cost of such a movement is not warranted in a stop watch. First, because the load to be carried by the train varies considerably whether the sweep second hand is running or not, and second, because careful adjustments made at the factory are almost invariably destroyed when the watch is repaired by the average jeweler.

An alarm clock without jewels can readily be regulated to keep time within one minute, in twenty-four hours. This rate for an interval of one minute, produces an error of ± 0.04 second. The inherent error of a mechanically perfect stop watch is five times this amount. While the rate of an alarm clock as used is sufficiently precise for use as a stop watch, it is true that it cannot be carried about without seriously disturbing the rate.

The addition of a few jewels properly applied as in the case of the seven-jewel movement removes this objection and permits even a closer rate adjustment. The addition of more than seven jewels serves only to reduce an already negligible error.

Errors due to Methods of Application of Start and Stop Mechanism and Mechanical Imperfections in some Typical Stop Watch Designs

The simplest, cheapest, and perhaps the most common stop watch is one without the usual hour and minute hands, having seven jewels. This watch, of Swiss make, is supplied to the trade under many names and models, differing slightly. The principle of operation is the same in all cases. The sweep second hand and minute hand, if any, are started and stopped by starting and stopping the balance.

Fig. 3 is a sketch showing how this is carried out in the type known as "Jockey Club." The balance and starting lever are shown in the stopped position.

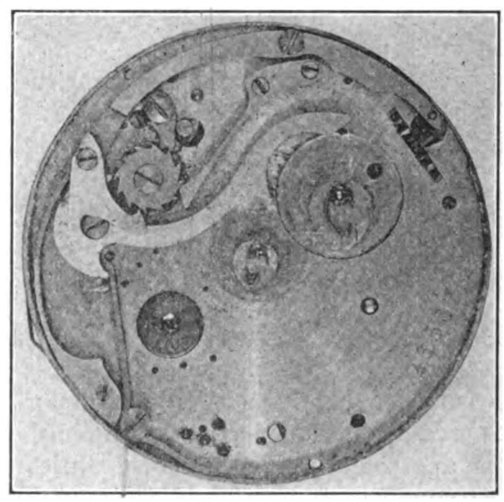

FIG. 4—JOCKEY CLUB
Under the dial with hands removed.

Pressing the stem, (not shown), starts the balance by snapping the starting lever about the right-hand screw, dragging the start and stop spring along the edge of the balance in the direction of the arrow, thereby setting the balance in motion.

Pressing the stem a second time stops the balance by returning the lever to the position shown.

Pressing the stem a third time returns the hands to zero by means of a "fly-back lever" and heart cams.

These are shown in Fig. 4, a view with dial removed. The sweep second hand is removed from the small heart cam in the center of the plate of the small minute hand from the large heart cam. The fly-back lever as shown is ready to return the hands to zero by striking these cams.

Frequent pounding of these cams by the fly-back lever which strikes a heavy blow enlarges the holes in the plate and in the heart cam sleeves, which are of brass, causing the sweep second hand to jump forward or backward on being started or stopped.

The heart cams and hands cannot be rigidly attached to the staffs in this type of watch, as returning them to zero position must necessarily move the whole train, therefore, they are friction driven. The C-shaped springs seen on the heart cams provide this drive. One end passes around a pin at the point of the cam and the other end passes through a slot in the sleeve, bearing against the staff which is slightly recessed to prevent the heart cams moving along the staff.

The C-spring is an additional source of error, for if tension is too weak it will not drive, and if too strong, friction with the staff causes a rolling action between spring and staff while being returned to zero, producing a torque between the two members at zero. This torque results in the sweep second hand jumping ahead or back upon starting, the direction depending upon whether the hand returned to zero from the right or left. This error increases as the holes in the sleeves are enlarged. It is seldom less than $^1/_5$, usually from $^2/_5$ to $^3/_5$, and frequently $^4/_5$ of a second or more.

Another source of error common to all types using heart cam return is due to adhesion of different amounts between the fly-back lever and each cheek of the heart cam. This causes the sweep second hand to be pulled ahead or back as the fly-back lever recedes when the watch is started. This error would still further be increased by the magnetization of the fly-back lever and heart cams. Once magnetized, it is practically impossible to remove the last trace of magnetism unless heating is resorted to, which is out of the question.

The magnitude of this error can be determined in a given case by repeatedly pressing the stem while the balance is prevented from running with the aid of a camel's hair brush, meanwhile noting the position of the second hand. The added error, due to the C-spring, must be noted while the balance is free, as shown by trial, after returning the hand to zero from the right and left.

Still another source of error present in all types to a greater or less degree is the effect of the jar due to starting and stopping operations upon the unbalanced sweep second member. This error may produce a movement of the hand forward or backward when starting or when stopping.

Perhaps the most serious error in this type of watch, certainly the most disconcerting one for the engineer, is due to the method of starting and stopping. It is problematical at what position of the balance swing the stop wire will interfere with the balance as the starting lever returns to the stop position. If the interference results in turning the roller jewel out of the fork so far that when started it will carry the pallet fork to the opposite banking pin, all well and good,

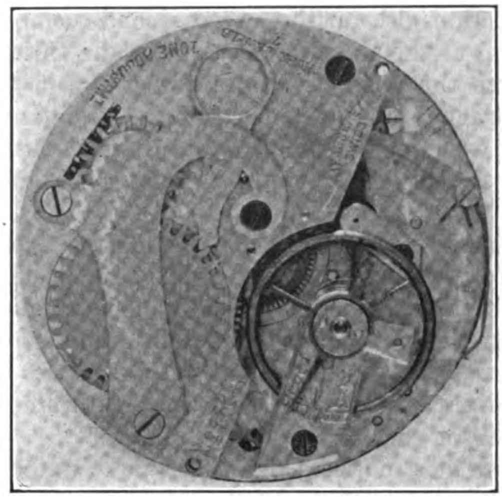

Fig. 5—Jockey Club

but it sometimes happens that when started, the roller jewel just returns to the fork without enough force to carry the fork over, and the watch does not start. More frequently the roller jewel returns to the fork with just sufficient force to carry it over, swinging a short distance beyond, with the result that an appreciable time is required for the balance to pick up to full motion. As the isochronal adjustment of these watches is in general very poor, considerable error results.

Fig. 5 is a back view of this type where the start and stop spring can be seen projecting slightly beyond the edge of the plate to the right. This picture gives a good idea of the general appearance and the relative positions of the starting lever and balance.

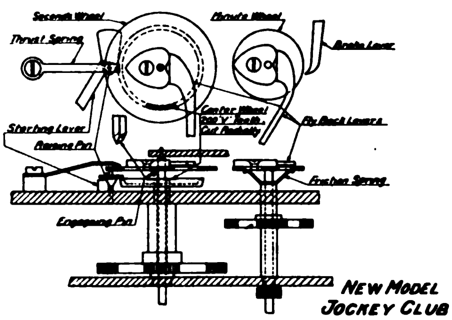

Fig. 6

Fig. 6 is a diagrammatic sketch of the new model Jockey Club. This model is without the usual hour and minute hands. The timing train runs continuously. The heart cams and hand are rigidly mounted on opposite ends of a staff forming the sweep second member. The staff of the seconds wheel of the tim-

ing train is a hollow and surrounds the staff of the sweep second member. The parts shown in the sketch are in position ready to start. The operations are as follow:

Pressing the stem, first removes the fly-back levers from the heart cams an instant before the starting lever moves away from the cone on the staff beneath the friction disk on the sweep second member. The removal of the starting lever allows the thrust spring to force the sweep second member downward until the engaging pin on the friction disk engages with the center wheel of the timing train, thereby carrying the sweep second hand forward in unison with the timing train.

Pressing the stem a second time returns the starting lever to the position shown, striking against the cone, elevating the raising pin, which, in turn, disengages the engaging pin and stops the second hand.

Pressing the stem the third time causes the fly-back levers to strike the heart cams, returning them to the position shown.

Errors most noticeable in this type of watch are due to play in the bearings of the raising pin, aggravated by the hammer blow action of the starting lever. The friction disk to which the heart cam is attached is clamped between the end of the raising pin and the thrust spring. During the process of engaging and disengaging with the center wheel, the downward motion of this disk forces the cone along the surface of the starting lever, resulting in a torque at the disk. This is further aggravated by the fact that the thrust spring, in moving up and down, produces friction that is not applied radially. These torques cause the sweep second hand to jump forward or backward when started and when stopped.

As previously pointed out, the timing train has 300 positions of rest per minute and is in motion 1/100th of a second in each 1/5 of a second. The center wheel has 200 V-shape teeth. If these teeth are adjusted so that the pin falls directly into the tooth space with the fork against one banking pin, it will not again fall directly into a tooth space until the fork has made three trips.

The magnitude of these errors can be observed by repeatedly pressing the stem while the fork is held against each of the banking pins in succession. An additional difficulty is met due to the action of the brake lever on the minute wheel. This wheel is driven by a friction spring to the minute wheel of the train. The hook end of the brake lever is applied to ratchet teeth at the edge of the minute wheel holding it against the operation of the train through the friction spring. If the torque of the friction spring is too great, the motion of the balance will be greatly reduced. If too small, it will not drive.

Fig. 7 is a view of the back of the watch showing clearly the relative positions of the fly-back lever, heart cam friction, disk and spring.

Another method for starting and stopping the sweep second hand is one in which the sweep second member carries a toothed wheel. An intermediate shaft carrying a coarse tooth pinion at the lower end, engaging with the fourth wheel of the train running with it continuously, carries at its upper end a fine toothed

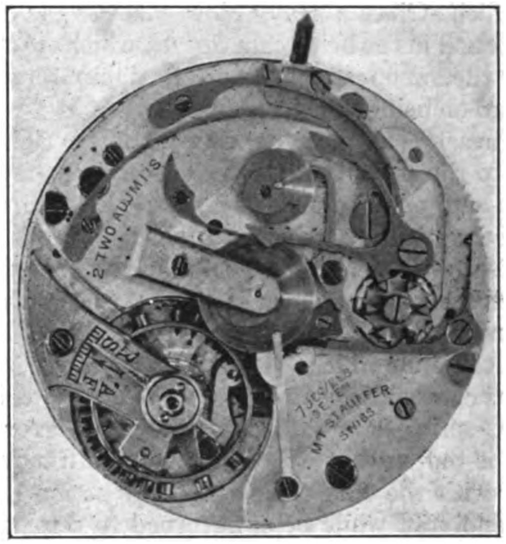

Fig. 7—New Model Jockey Club

pinion. This pinion is engaged with the toothed wheel to start, and disengaged to stop the sweep second hand.

Fig. 8 is a diagrammatic sketch of a watch of this type known as New York Standard. This type of watch has in addition to sweep second hand, the regular hour and minute hands.

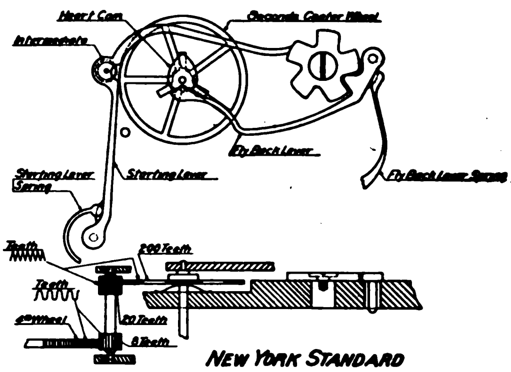

Fig. 8

Parts are shown in position ready for start. The operations are as follow:

Pressing the stem the first time turns the cam wheel, raising fly-back lever from heart cam just before intermediate is allowed to fall into mesh with the center seconds wheel starting sweep second hand.

Pressing the stem the second time disengages intermediate, stopping second hand.

Pressing the stem the third time allows fly-back hammer to strike heart cam, returning second hand to zero (position shown).

Sources of error in this type of watch are due to necessary play between the coarse tooth pinion and the fourth wheel, and play in the bearings of intermediate shaft. This amounts to $^4/_5$ of a second or more. The magnitude can be determined by putting parts in the running position, and with the balance stopped

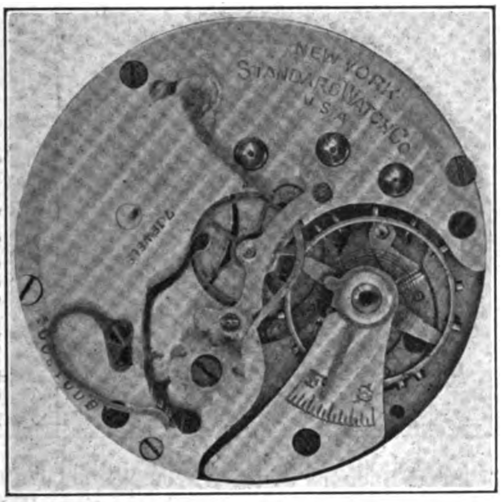

Fig. 9—New York Standard

note freedom of sweep second hand necessary to take up lost motion to fourth wheel. If it were not for the three-legged friction spring, the sweep second hand would whip back and forth by this amount with each beat of the watch. The error due to this cause is uncertain both as to magnitude and sign within the limits specified.

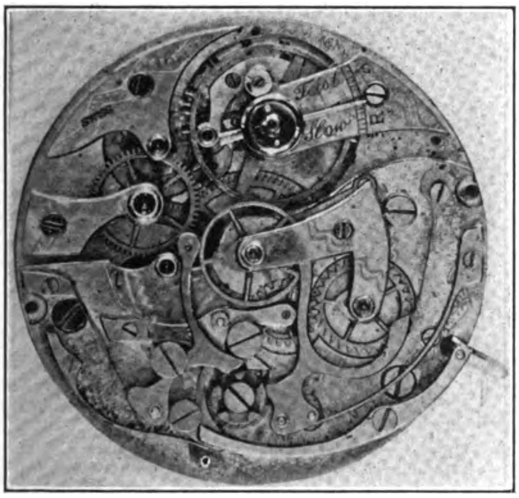

Fig. 10—Swiss Watch
With similar acting parts to the New York Standard.

Additional errors are due to the seconds center wheel having 200 teeth, while the intermediate has 300 positions of rest.

The intermediate gear strikes the same point on the seconds center wheel each time at starting.

Constant operation causes teeth to be deformed and produces jumping of the sweep second hand upon starting.

A jar on starting and stopping affects the sweep second member.

Fig. 9 is a back view showing the relative position of intermediate, starting lever, fly-back hammer, and tooth wheel, on sweep second member.

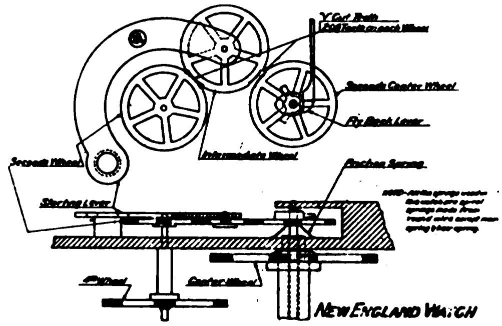

Fig. 11

Fig. 10 is a more complicated movement of the same type, of Swiss manufacture. This movement has, in addition to the sweep second hand, a minute counter advanced upon the completion of each revolution of the sweep second member. This is a regular fifteen-jewel movement with the addition of two ring stone jewels on the upper staffs of the sweep second member, and minute counter staffs, probably for appearance only as similar jewels are not found upon the lower ends.

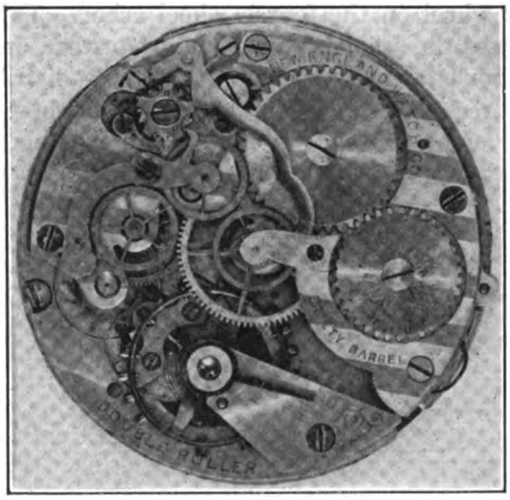

Fig. 12—New England Watch

In another type of movement the sweep second member is started and stopped by an intermediate gear running continuously with a similar gear mounted on the fourth wheel arbor above the back plate. The intermediate gear is thrown into and out of mesh with a tooth wheel on the sweep second member.

Fig. 11 is a diagrammatic sketch of a watch of this type known as the New England. Sequence of operations is the same as described for the New York

Standard type. The principal errors in this movement are due to 200 V teeth being used on all three wheels while the balance has 300 positions of rest. The intermediate gear strikes the same point on second center wheel deforming the teeth. Play in teeth of intermediate, and center play in the teeth between intermediate second center wheel and seconds wheel, which

FIG. 13—ALLION À VERSAILLES
For aviation in France.

has to be quite as large as the intermediate, is carried bodily about a pivot located not at the center of the seconds wheel. The intermediate in engaging with the center seconds wheel is made to rotate about the seconds wheel on the fourth wheel arbor. This usually causes the second hand to jump forward or backward upon starting, depending upon the distribution of the three wheels in different types of watches. This jump is augmented by the errors previously noted and frequently amounts to $^2/_5$ of a second.

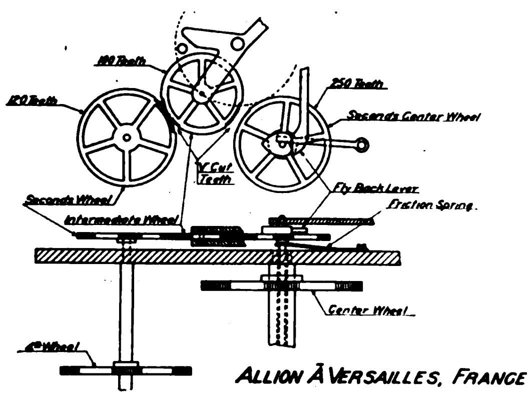

FIG. 14

Fig. 12 is a back view showing the relative position of seconds wheel intermediate, center seconds wheel heart cam, and fly-back lever.

Fig. 13 is a Swiss movement of a similar type, showing the relative positions of parts.

Fig. 14 is a diagrammatic sketch of the same watch known as "Allion a Versailles," France. The criticism of the New England watch applies to this type.

It will be noted that the intermediate swings about a pivot, less favorably located for accuracy, and that

FIG. 15—SPLIT SECONDS SWISS WATCH WHICH HAS ONLY THE TWO SWEEP SECOND HANDS AND MINUTE HAND
The parts shown here control one sweep second hand and the minute hand. Balance runs all the time.

the number of teeth is still not in agreement with the train positions of rest. The majority of the high-grade watches, (by that meaning high price) follow this general principle of operation.

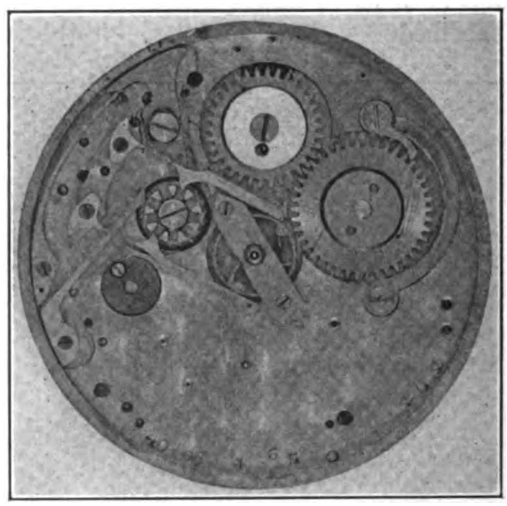

FIG. 16—SPLIT SECONDS SWISS WATCH
The parts shown here control the second sweep second hand. The function is to stop the hand, and release to continue in step with the other sweep second hand to a point at which it is to be stopped again. In other words this hand can only be stopped or released to run with the other sweep second hand.

Another principle of operation is that a small intermediate is made to engage with seconds wheel and second center wheel.

Fig. 15 is a back view showing the distribution of parts of a split second timer without the usual hour

and minute hand. It shows clearly the imitation compensated balance.

Fig. 16 is a view with the dial removed showing the distribution of parts necessary to operate the secondary sweep second hand that can be stopped independently of the main hand.

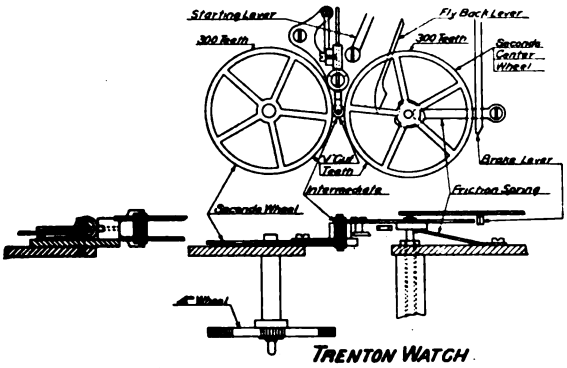

Fig. 17

Fig. 17 is a diagrammatic sketch of a watch of this type known as the Trenton watch, manufactured in this country many years ago.

The starting and stopping operations are as follows: Parts are shown in the running position. Pressing the stem the first time stops the sweep second hand by causing the starting lever to move to the left, striking the upper edge of the disk clamped to the staff supporting the intermediate, thereby turning the intermediate about this staff out of contact with seconds center wheel. This event takes place an instant before the brake lever falls in contact with the seconds center wheel, thus securely holding the sweep second member in position.

Fig. 18—Trenton Watch

Pressing the stem the second time causes the sweep second member to return to zero position by the fly-back hammer striking heart cam, the brake lever having been removed from sweep second member an instant before.

Pressing the stem a third time starts second hand by removing the starting lever from the disk on the intermediate, allowing the intermediate to engage, the fly-back lever having been removed from heart cam an instant before. In this watch it will be noted that the seconds center wheel and seconds wheel on fourth

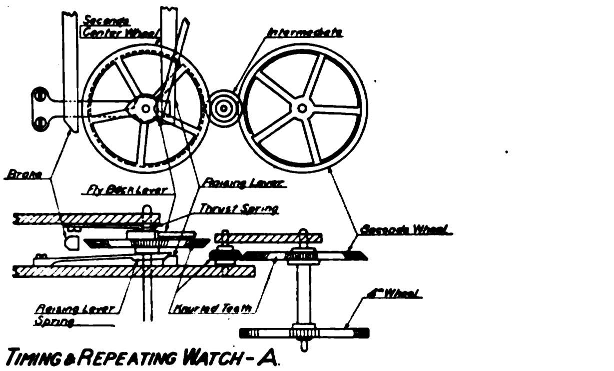

Fig. 19

wheel arbor have each 300 V-teeth; the error due to this source is consequently negligible.

The source of errors in this type are due to the intermediate striking at the same point on sweep second member repeatedly at start and end play in the supporting member. Movement of staff of sweep second member, due to application of either brake or intermediate upon stopping or starting, causes the hand to jump forward or backward. This is due to the necessity for clearance between the staff of the sweep second member and the hollow staff of the train, having no bearing provided above seconds center wheel.

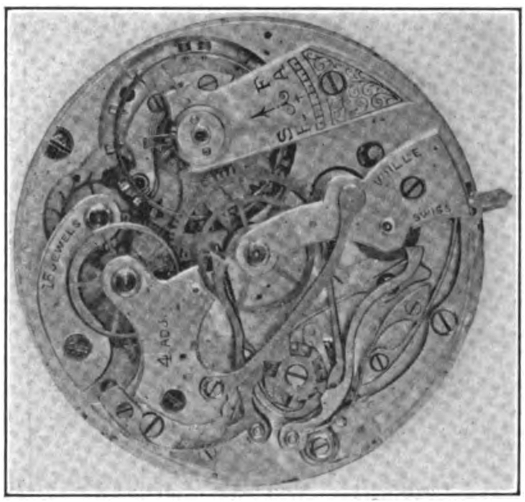

Fig. 20—Timing and Repeating Watch—A

The difficulty met with in adjusting this watch is due to necessity for play in the support of the intermediate. Without this it would be impossible to have the upper edge of the intermediate engaged with the seconds center wheel at the top to the right, and at the same time with the seconds wheel at the bottom to

the left, and remain engaged while the wheels make a complete revolution.

Fig. 18 is a back view showing the relative positions of parts.

Fig. 19 is a diagrammatic sketch of another type known as "Timing and Repeating," in which parts are shown

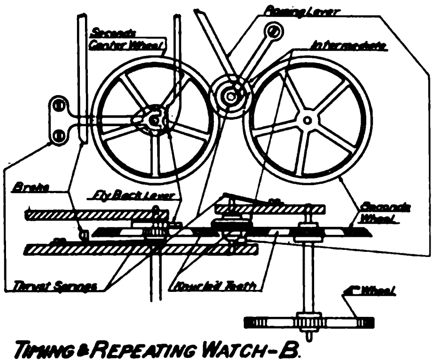

Fig. 21

in the stopped position, ready for starting. The operations are as follows:

Pressing the stem the first time removes the fly-back lever from the heart cam just before the raising lever is removed from beneath the raising lever spring, allowing the thrust spring to force the second center wheel into contact with the intermediate, carrying it also in contact with the seconds wheel.

The principal source of error in this type is due to teeth being knurled. The number is indefinite. The intermediate strikes repeatedly at the same point at start. The thrust spring bears on sweep second mem-

Fig. 22—Timing and Repeating Watch—B

ber at all times; the result is that unless the wheels are nearly perfectly true, the watch stops because there is not sufficient power in the train to force the sweep second member up against the thrust spring. The starting and stopping are accomplished by raising and lowering the sweep second member. The method described produces torques, causing the sweep second hand to jump forward or backward when started and when stopped. The extent of this error is in general 2/5 of a second and frequently more.

Fig. 20 is a back view showing the relative positions of parts. This watch has regular hour and minute hands in addition to sweep second and minute counter.

Fig. 21 is a diagrammatic sketch of a later model of the same make in which the starting and stopping are accomplished by raising and lowering the intermediate. This is a marked improvement over the previous model as it avoids the necessity for raising and lowering the staff carrying the sweep second member. With this exception the errors remain as in the previous model.

There is, however, a difficulty met with in adjusting the tension of the thrust spring at the top of the intermediate and beneath the seconds center wheel so that the former will have sufficient torque to oppose the latter and at the same tine carry the intermediate into contact with the seconds wheel. Any irregularity in either of the large wheels causes slipping. The freedom that must be allowed for the bearings of intermediate, second wheels, and center second wheel, causes a wedging action due to springs and rotation of parts. Any inequality in the teeth of the big gears will force a pair of members out of contact, and slipping results. This source of error is difficult to discover. For this reason, and for many others, at least two watches should be used for timing all observations.

Conclusions

Due to inherent errors of timing train, and those due to mechanical limitations and design, practically nothing is gained in accuracy by increasing the number of jewels beyond the standard seven-jewel movement.

An attempt has been made to reduce the inherent error in at least one instance by increasing the rate of vibration of the balance, but the price at which it was offered was out of all reason considering the accuracy gained and the cost of manufacture.

Some of the larger errors do not follow the law of probability, for while the errors may be either plus or minus, and vary somewhat in magnitude, some at least depend upon the interval of time being measured, as for instance, in the case of the Jockey Club type of stop watch if the interval being timed is less than thirty seconds, the hand will jump forward upon being started again. If the interval is more than thirty-five seconds the hand will jump backward on starting again.

The sources of error in a watch are such that at least two watches should be used simultaneously for timing an event, timing intervals of varying length if possible, the mean of all observations to be taken.

The stop watch applied to engineering measurements is not sufficiently robust for the purpose, and it is to be hoped that manufacturers will make a special effort to produce a stop watch suitable for this class of service.

Notes on the Effect of Heat on Impregnated Paper from Cable Insulation

BY WALLACE S. CLARK
General Electric Co., Schenectady, N. Y.

THE tests outlined below were made to determine at what temperature marked deterioration in the paper of impregnated paper cable took place. There are many shots well off the target in these results, although the average were determined from something over six hundred readings. Anyone who is familiar with the manufacture of paper and with the handling of it, knows the wide variation which occurs in different parts of the same sheet. The maximum tensile strength in a series of tests is frequently twice the minimum.

The first series of tests was started in December, 1917, and completed nine months later.

The sample was three-conductor cable, lead-jacketed, 4 ft. long, with 00 cylindrical conductors, saturated with a compound composed of resin and petrolatum. The paper wall on the individual conductors was 9/32 in. of 0.005 Manila paper and the overall jacket was 7/32 in. of 0.008 Manila paper; lead jacket 1/8 in. The sample was cut from a cable coming through in the regular course of production and was representative of ordinary manufacturing practise.

A narrow section was cut off and six strips of paper from the outer jacket were unwound and tested for tensile strength. The distance between jaws was approximately 7 in., rate of separation 20 in. per minute, average tensile strength 7343 lb. per sq. inch. Each end of the cable was then sealed and it was placed vertically in an oven. This oven had the following temperature cycle:

From 7 a. m., Monday, to 12 noon, Saturday, average temperature ran from 68 to 74 deg. cent. Steam was shut off at 12 oclock, Saturday, and by 6 a. m., Monday, the temperature had dropped to 30 deg. cent., when the steam was again turned on.

At different times short sections were sawed off from the sample, and the sample resealed and put back into the oven. The results showed average tensile strength given in Table 1.

TABLE I
Average Tensile Strength per Sq. Inch

Not heated	1 mo. bake	2 mos. bake	4 mos. bake	6 mos. bake
7343 lb.	7816 lb.	7338 lb.	7088 lb.	8290 lb.

The above samples were from the outer jacket. Samples of paper from the individual conductors showed similar results. Samples were also bent and twisted in the fingers to detect brittleness.

To be presented at the 9th Midwinter Convention of the A. I. E. E., February 16-18, 1921.

The same sample that had the six months' bake, with each end sealed, was then placed in an oven at a temperature of 100 deg. cent. At the end of the first month the average tensile strength was 7240 lb. per sq. inch; at the end of the second month, 7173 lb. per sq. inch.

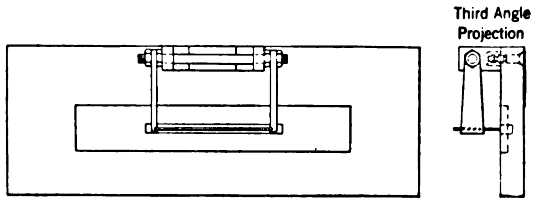

FIG. 1—APPARATUS FOR MAKING BREAK-DOWN VOLTAGE TESTS ON NARROW STRIPS OF INSULATION—PLAN AND ELEVATION

In the spring of 1920 another test on the same size and insulation was undertaken. In this case, seven samples were cut from one length of cable coming through in regular production. Each end of each sample was sealed. Sample A was held as a check; sample B was heated for 30 days at 100 deg. cent.' sample C was heated 60 days at 100 deg. cent., sample D—90 days at 100 deg. cent., sample E—30 days at 110 deg., sample F—60 days at 110 deg., and sample G—90 days at 110 deg. On each of the paper samples a break-down test was made, using the so-called knife-blade apparatus shown in Fig. 1.

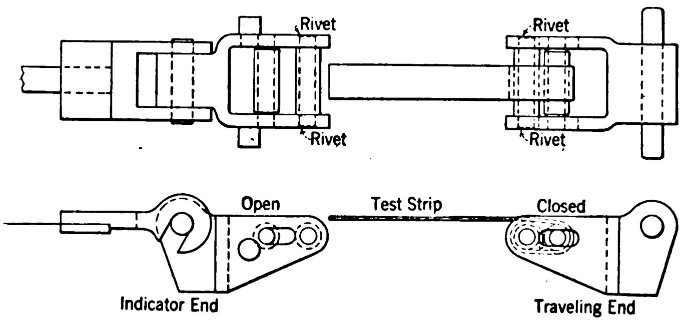

FIG. 2—GRIPS FOR MACHINE FOR TESTING TENSILE STRENGTH OF CABLE PAPER

Straight tensile strength tests were made, and in addition tensile strength tests were made where the stress applied to one edge of the paper was greater than the other. Paper was folded over the rollers of the grip shown in Fig. 2, the roller at one end being slightly tapered, thus applying greater tension to one edge than to the other when the jaws were separated. The average results of these tests are shown in Table 2.

TABLE II

	Break-down volts per mil	Breaking strain lb. per sq. inch	Tearing strain lb. per sq. inch

We note from this table that the ratio of tearing strength to the average breaking strength in sample A, cable not heated after manufacture, is 0.72; in sample D, heated 90 days at 100 deg., 0.57, and in sample G, heated 90 days at 110 deg., 0.64. This shows definitely that the tensile strength of the paper deteriorates less rapidly than its resistance to tearing. The higher rate of deterioration at 110 deg. cent. is clear and is well marked by comparing the results from sample D, 90-day bake at 100 deg., with sample E, 30-day bake at 110 deg., the deterioration in 30 days at 110 deg. being practically equal to deterioration in 90 days at 100 deg. From these results, we can say in a preliminary way, that deterioration at 70 deg. cent. is negligible; at 100 deg. is marked in 90 days; at 110 deg. is marked in 30 days, applying to the particular quality of paper and impregnating compound which were under test.

A load with a two-hour peak, allowing such peak to occur for 30 days in each year, would give 60 hours yearly operation at maximum temperature, which we will assume at 100 deg. cent. It is evident that the cable on this basis could be used for many years, operating at 100 deg. cent. as its peak temperature, before reaching the stage of deterioration obtained in the 90-day test at 100 deg. cent. It is, of course, impossible to state the exact time because we do not know the rate of deterioration at temperatures below 100 deg. cent.

From an examination of the cable and paper taken from sample G, there is no question in the writer's mind but that cable with paper in this condition would be perfectly safe for operation at low voltages. Further the writer believes that cable so treated could have been withdrawn from conduit and reinstalled. Briefly, the temperature limit fixed for the operation of a low-tension cable, to avoid undue deterioration, must take into consideration the length of time during which temperature is maintained.

APPENDIX

Tensile Strength

The samples for testing are taken from the finished cable after it is leaded. In case of a multiple-conductor cable, part of the samples are taken from the overall jacket and part from each of the individual conductors. If the strips are over ¾ in. wide, they are cut to ¾-in. width with a steel straight edge and a sharp pointed knife. The jaws of our testing machine will not take strips over ¾ in. wide. The test strips should be about 12 in. long so that the distance between jaws will be about 7 in. When the strips are placed in the jaws, it is important that they are put in straight, so as to get a straight pull. The jaw travels at the rate of 20 in. per minute, the machine used being our standard rubber testing machine which registers the pounds pull when the sample breaks.

Tearing Test

This test is made the same as tensile strength except that the back roller in the traveling jaw has a taper of 0.025 in. per inch. When the tearing test is made, the straight roller is taken out of the movable jaw and the taper roller inserted in its place.

Creasing Test

Samples of paper as described for tensile strength test are looped back on themselves and flattened down with a 10-lb. weight placed over the loop for a period of one minute, thus making a crease in the paper. This method is used in order to make a uniform crease in all samples. The strips are then straightened out and put into the machine using straight rollers in the jaws, and the tensile strength measured.

The jaws used for making the tests are shown in Fig. 2.

THE YEAR'S PROGRESS IN RADIO TELEPHONY

In connection with research work at the Bureau of Standards on radio telephony, it is necessary to keep in touch with progress in this subject elsewhere. A review of recent developments and achievements has been prepared for publication in the *Electrical World.*

The past year has witnessed steady progress and increasing public interest in radio telephony. Voice transmission by radio waves has advanced from the experimental stage to established practise, for distances of a few hundred miles, and since all inherent difficulties have been surmounted, it is actually possible to carry on reliable radio telephony over as great a distance as ordinary wire telephony. It seems probable that commercial telephony across the Atlantic will be an established fact in the not far distant future. The quality of transmitted speech or music is as perfect as in ordinary wire telephony.

Regulation of Frequency for Measurement Purposes

BY B. H. SMITH

Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

IT happens very often that it is desirable or necessary to transmit a quantitative indication to a more or less remote point. For instance, in a modern power system with its various sources of power, the load despatcher may wish to know the amount of power generated in a station perhaps several miles away, so that he may be able to better distribute his load. In addition, it may be desirable to regulate automatically the distribution of power as well as limit the amount that is received from a distant point. In this connection the problem may not be simply that of limiting the indicated power but of measuring and limiting the integrated demand over a definite time period. Of a different nature is the problem of recording at widely distributed points various operations in an industrial plant so that the results can be compared on the basis of the exact time of occurrence. satisfactory performance giving accuracy and high torque has been developed, making use of the automobile speedometer principle of a revolving magnet acting on an aluminum disk.

The purpose of this paper is to consider a number of metering systems where the frequency of a circuit is controlled in order to transmit an electrical condition to a remote point and to bring out the adaptability of this quantity for such purposes.

In 1917 the C. M. & St. Paul R. R. was confronted with the problem of measuring the power consumed on its latest electrified section extending from Tacoma and Seattle for a distance of about 200 miles east. It was decided to measure the power received at the various substations, Taunton, Cedar Falls, and Renton, and transmit the measurements to the dispatcher's office where they would be totalized and recorded.

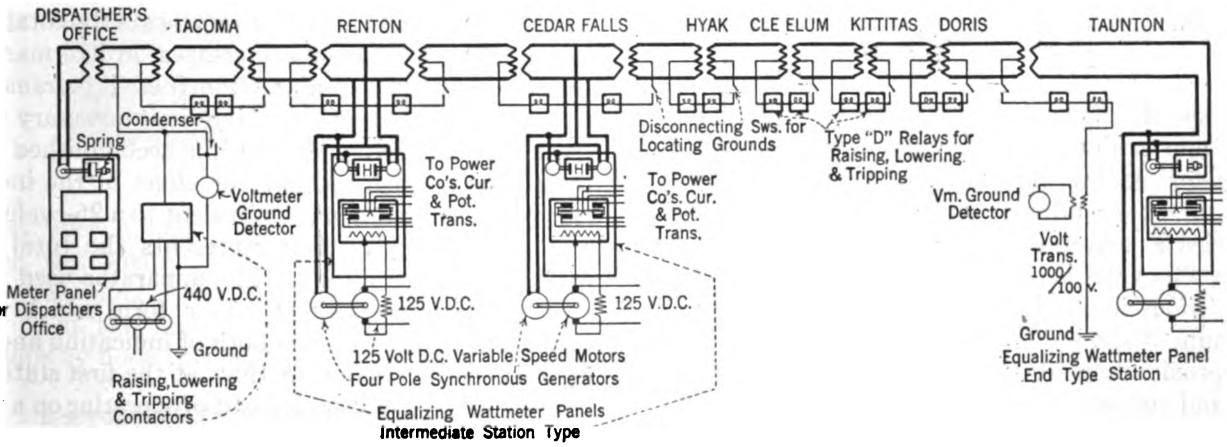

FIG. 1—DIAGRAM OF POWER INDICATING AND LIMITING SYSTEM, CHICAGO, MILWAUKEE AND ST. PAUL R. R. CO.

For all of the above problems frequency lends itself as a quantity which can be made proportional to a given indication and transmitted without any change for practically any distance. In this respect it stands out as being far superior to the transmission of energy or voltage or current. The transmission of voltage is affected by resistance in circuit, the transmission of current is affected by leakage and induction and the transmission of energy is affected by both of these quantities. Frequency is not affected by any of these quantities. The only problem is its satisfactory control and measurement. The speed control of a small motor-generator set to give a desired speed within wide limits has been accomplished with more or less success in the past, but the frequency meter in its ordinary form is quite unsuitable for accurate measurement purposes. A new type of frequency meter of most

For much of the distance the climatic conditions are very severe and, especially along the coast, the weather is so wet that leakage of electrical energy from any kind of outdoor circuit is very great, and any method making use of quantitative transmission of current is out of the question.

The use of frequency was proposed as a suitable method, because frequency is a quantity which can be carried over a long distance without being subject to changes, and the details of the apparatus as installed some months ago are perhaps worthy of our attention as being an example of the most extensive application of the use of frequency for measuring purposes in service up to the present time. First of all, it is necessary to obtain from some source which will allow of regulation a frequency which can be made proportionate to the measured power. This is accomplished by connecting a wattmeter to a small a-c. generator in such a way that the speed, and hence frequency of

To be presented at the 9th Midwinter Convention of the A. I. E. E., February 16-18, 1921.

the generator, is proportionate to the power received. This is done as follows:

At the first substation, Taunton, a small synchronous motor is driven from an a-c. generator, and through a revolving magnet acting on an aluminum disk produces a torque which over a wide range is proportionate

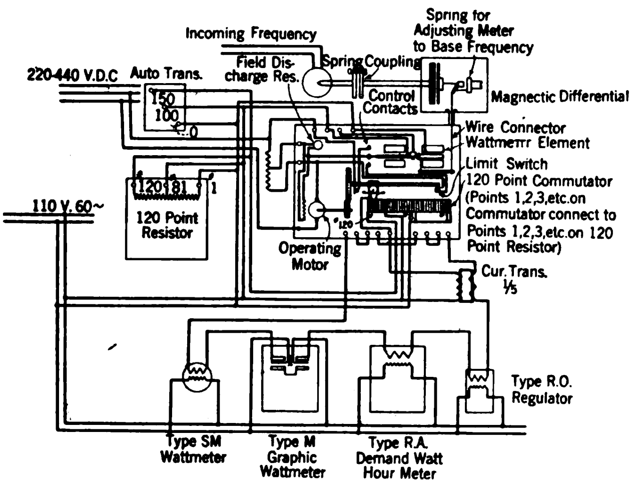

FIG. 2—DIAGRAM OF DISPATCHER'S OFFICE POWER INDICATING AND LIMITING SYSTEM

to the speed. This torque is balanced with the wattmeter and maintained so that with any change in wattmeter reading the speed changes accordingly.

To take care of zero load a "base" frequency of 25 cycles is maintained, so that if the load is zero, exactly 25 cycles is sent out to the next station, and with various loads the frequency is increased up to a maximum of about 60 cycles. The outgoing frequency at approximately 100 volts is transformed to 2000 volts and transmitted to the next station. Here, and at three more stations, at intervals of about thirty miles there is no power received and the lines are

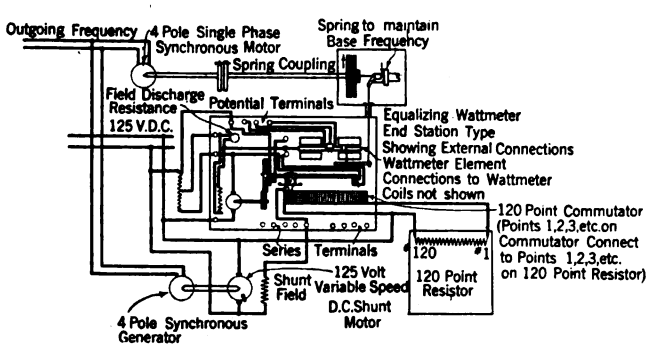

FIG. 3—DIAGRAM OF END STATION METER POWER INDICATING AND LIMITING SYSTEM—CHICAGO, MILWAUKEE AND ST. PAUL R. R. CO.

brought into the station only for the purpose of bringing out the phantom or power control circuit which will be mentioned later.

At the fifth station, Cedar Falls, the frequency is increased by an amount proportionate to the power being received at that station. It is not done directly however, but another generator is introduced and so controlled that its speed corresponds to the incoming frequency plus any power coming in on its own meter. The incoming frequency operates a synchronous motor similar to the one at Taunton and shown as the left hand motor in Fig. 8, its effect is added to the power

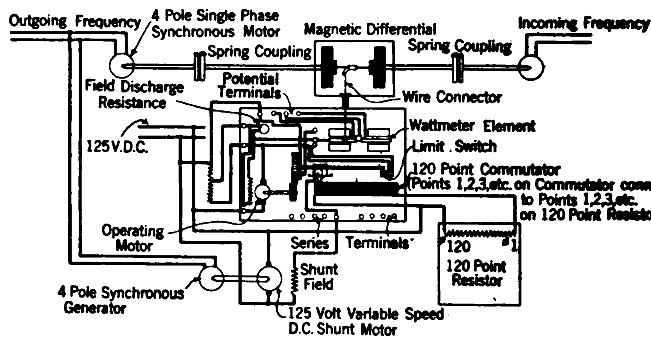

FIG. 4—EQUALIZING WATTMETER, INTERMEDIATE STATION TYPE, SHOWING EXTERNAL CONNECTIONS—POWER INDICATING AND LIMITING SYSTEM

incoming at Cedar Falls, and the outgoing frequency is balanced against it so that it represents the total power so far. The frequency is increased in like manner at the next station, Renton, and from there it is transmitted to the dispatcher's office. Here it is necessary to subtract the base frequency which is accomplished simply by a spring which opposes the effect of the incoming frequency by an amount equivalent to a 25-cycle speed, and the remainder then represents the total power received by the railroad. The apparatus used to convert the frequency effect into a form which can be shown on ordinary meters both of indicating and watt-hour types, is similar to that at the first station, but the control mechanism, instead of operating on a motor-generator set only controls the quantity of current in a local circuit through suitable slide resistance, and this current is passed through standard indicating, recording, integrating and demand meters.

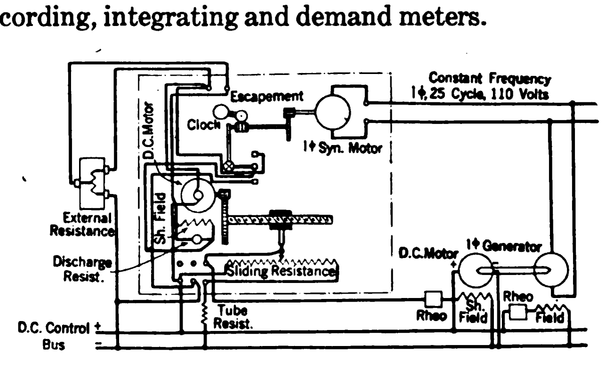

FIG. 5—DIAGRAM OF CONNECTIONS OF CONSTANT-FREQUENCY REGULATOR

It was mentioned above that at certain stations, the metering circuit was led in only for purposes of bringing out the power control circuit. This circuit is supplied from a 440-volt direct-current generator at the dispatcher's office. One generator terminal is grounded and the other is led into the frequency

circuit through the middle point of the 2000-volt transformer, then it divides between two wires and passes through the whole line to Taunton, where it is connected to ground as a return circuit. The experience to date with this circuit furnished the best evidence that quantitative measurement of a direct-current indi-

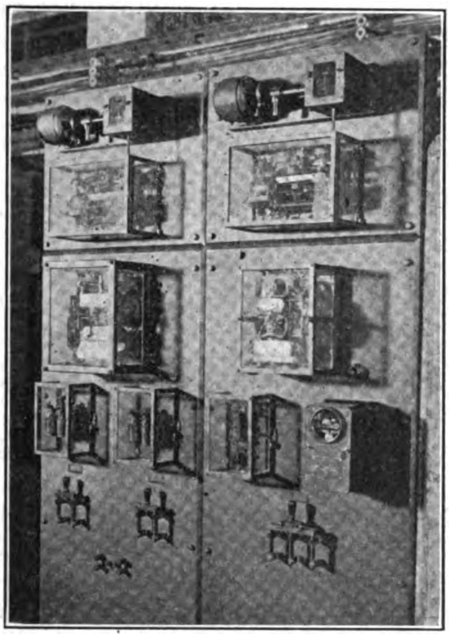

FIG. 6

cation over a long distance is out of the question under wet weather conditions. It was found in the very beginning, that about six milliamperes would leak from the line on an ordinary foggy morning. Perhaps by noon this leakage would entirely disappear.

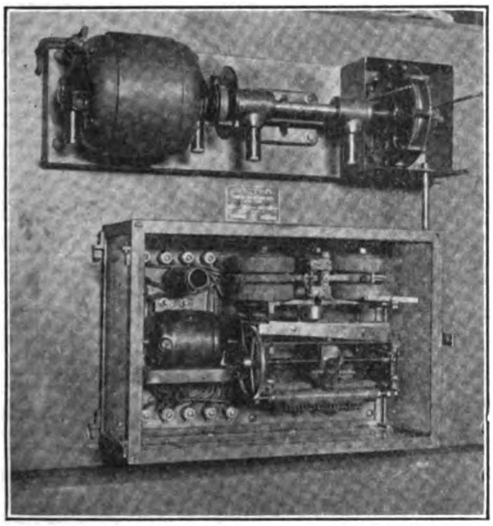

FIG. 7

This quantity is small but the control impulses sent over the line were only about 15 or 20 milliamperes, hence the percentage of leakage current was rather high. Later on there was evidence of much greater leakage, and at times it was impossible to get the proper control impulse through to the substations.

There was also found to be, especially along certain sections, a great deal of a-c. induction from the high-voltage power transmission line, and this tended to make the a-c. relays inoperative; but the effect on the metering frequency transmission was unnoticeable. This induction was, however, readily overcome by interposing in the circuit suitable resonant apparatus. It is not believed that the effects of ground potential have been serious, but recently there has been a great deal of apparent leakage from the 3000-volt power feeders into the circuit, so that the control impulses from the dispatcher's office at times are entirely overbalanced.

The transmission of the frequency indications, however, has been practically unimpaired under all sorts of conditions except where the line itself has been broken or accidentally grounded, and so far it can be said that this application of frequency control and transmission for metering purposes has more than met the expectations of all concerned.

Another application of frequency control of more recent date is being worked out in a large industrial plant. Here it is desired to record various operations

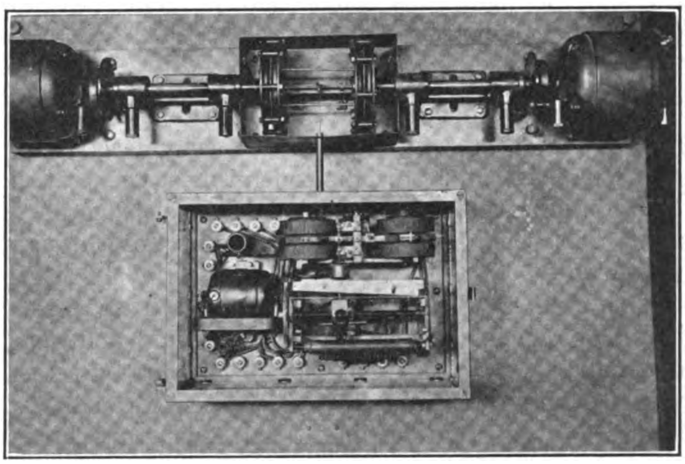

FIG. 8

in widely separated areas about the plant in such a way that indications can be compared on a basis of the exact time at which they occur. The timing mechanism of the various meters are operated by small synchronous motors and these are supplied from a circuit, the frequency of which is controlled by a master clock so that the integrated frequency is proportional to absolutely correct time. Thus at any point a synchronous motor can be connected to the circuit and with proper gearing made to drive clock hands or timing devices, and these will indicate with no error.

Fig. 5 is a diagram of the essential features of the control apparatus.

The speed of a small motor-generator set is balanced against a clock mechanism through a differential which operates the speed-controlling contacts. The differential is simply a sliding worm which moves forward

slightly when the speed gets ahead of the clock, and backwards, if the speed falls behind, thus operating the contacts so that the speed is brought back to the proper value. The correct speed and frequency thus obtained are transmitted to the various parts of the plant, and small synchronous motors operate the various timing devices. By this system there is ample power for a high-speed timing device, the various meters will agree with each other to within a small fraction of a second, and the whole system may be kept within two or three seconds of standard time. The central apparatus can be regulated for fast and slow speed in the same manner as a watch, and if after running for a length of time the system is found to be slightly fast or slow it can be speeded up or slowed down quickly by hand control and brought to agreement with wireless signals or other indication of correct time. Then a slight adjustment of the regulator will suffice to keep the system as nearly correct as can be expected from a good timepiece.

NOTES ON PROGRESS OF THE USE OF ELECTRICITY IN THE INDUSTRIAL AND DOMESTIC FIELD

BY P. H. ADAMS

Public Service Electric Co., Newark, N. J.

The use of electricity for industrial and domestic power purposes on a commercial scale began after the middle of the nineteenth century. In both of these fields it was first used for illumination, and several years passed before any other use was made of it. The development which followed the introduction of the electric light was such that it seems best to treat the two fields separately.

The Industrial Field

Gramme discovered in 1873 that one of his ring-wound generators would revolve when electrically connected to a similar machine operating as a generator. Little practical use was made of this knowledge until after 1880, when many improvements in motor design were made.

The first motors used were connected to series lighting circuits as well as to multiple circuits and were of small size. In one instance 18 motors in series were operated with the power required for one arc lamp. Motor drive for industrial sewing machines was one of the first applications to industry. Printing presses were also among the early motor-driven machines. The New York Gold & Stock Exchange used a three or four-horse power motor to drive about fifty tickers. This application was very satisfactory.

It is estimated that in 1886, there were about five thousand small motors in use in the United States.

The first Edison central station, that of the Edison Illuminating Co. of New York, was put into service in 1882, but there is no record of any motor load for industrial purposes on this station until the Edison motor was introduced in 1888. Four hundred and seventy horse power in industrial motors were supplied with power from this station in 1889. The first of these motors were used to drive printing presses. One of the motors put in service at this time was still in operation in 1912 and had cost only $25.00 for repairs during 22 years of service.

The growth of the use of electric power for industrial purposes was slow during this first decade, mainly because the art was in its infancy and discoveries and inventions, making the application possible, were just being made. The estimated total horse power of electric motors in service at the close of 1890 is placed at about 25,000 in the records of the National Electric Light Association.

Nikola Tesla and others introduced the polyphase generator and motor, making their first exhibition at the Frankfort Electrical Exposition in 1891. After a short period of development this type of equipment became the greatest factor in promoting the use of electric power in industry.

The development of the direct-current motor also advanced rapidly during this last decade of the nineteenth century and at its close the estimated aggregate horse power of electric motors in service is estimated at 495,000, an increase of about 1900 per cent in ten years.

This figure grew to more than 4,800,000 horse power by 1909, and the next five years saw another increase of over 80 per cent making a total of approximately 9,000,000 horse power in 1914. The estimated total as of January 1, 1920 exceeds 15,000,000 horse power, an increase of 3,000 per cent in 19 years.

The correction of the power factor of industrial loads has become of prime importance to the central station, and the static condenser, a commercial product of recent years, has come into wide use for this purpose. In this connection, the increased use of the synchronous motor for industrial drive is an interesting development. The rubber industry and many others are now using synchronous motors on a large scale.

Another new development is the electric shovel. This development provides a power shovel which can be used in almost any location. Electricity is now used in almost every phase of the steel industry. The fractional horse power motor has attained a wide application in the industrial field. Labor saving de-

vices for almost every conceivable purpose are now available, which do more and better work than hand labor ever accomplished.

Electricity is used to a greater or less extent in every part of the industrial field and its popularity, because of its economy, cleanliness and simplicity of application, is so great that the demand for motors and all other equipment now exceeds the combined output of all the manufacturers of electrical apparatus.

The Domestic Field

Benjamin Franklin, in 1749, demonstrated the fact that cooking could be done with electricity but almost a century and a half passed before practical use was made of this knowledge.

The electric fan was the first motor-driven device for the household and was used in the early eighties.

Heating devices came next, and in 1890 and '91, several companies began to produce heating and cooking devices of various kinds. Little, however, was accomplished in the commercial way until 1901 or 1902.

The advent of the efficient fractional horse power motor of today has caused the development of innumerable labor-saving devices for the modern home.

The second decade of the twentieth century has brought marked improvement in all household appliances and many new ones.

A partial list of the appliances obtainable today follows:

Motor-Driven. Washing machines, ironing machines vacuum cleaners, grinders, polishing machines, pianos, ice cream freezers, sewing machines, refrigerating machines, talking machines, dish washers, ventilating devices, and many others.

Stationary Devices. Ranges, heaters, toasters, fireless cookers, toilet devices, medical appliances, and others too numerous to mention.

The number of fractional horse power motors required for washing machines in 1920, by one large manufacturer, is over 500,000. This gives an idea of the extent to which the use of household devices has grown.

The total business in strictly domestic electrical appliance merchandise for 1920 may be conservatively estimated at five hundred million dollars.

The demand for fractional horse power motors is so great that delivery one year from the receipt of order is about the best that can be obtained. A similar condition exists in other lines of domestic appliances.

PERFORMANCE OF STARTING AND LIGHTING BATTERIES

In connection with the preparation of specifications for starting and lighting batteries requested by the Motor Transport Corps of the Army, the Bureau of Standards has made a brief study of the performance of these batteries in the operation of a few of the various types of automobiles; the experiments having been made on cars in ordinary running order.

Performance curves shown in the instantaneous demands upon the batteries when cranking the engines have been obtained by means of oscillograph records, these records showing characteristic differences typical of the design and condition of the various engines and starter systems. The initial values of current and voltage, which cannot be obtained by the use of ordinary indicating instruments, are shown at the time of closing the starter switch. After the starter has begun to turn, the current decreases rapidly, pulsating with the compression of the successive cylinders. An interpretation of the curves shows that much additional information could be obtained with respect to the operation of the starter system and the engine itself.

The results which have been secured are to be regarded as suggestive rather than quantitative measurements of performance. They indicate the possibility of using this method for the study of problems relating to lubrication, ignition, compression, and distributor action. In addition, an exact method is secured for measuring the speed from one revolution to another. The characteristics of the charging current when the engine was running were also studied. Measurements have been made at different speeds, different throttle openings, and different temperatures.

High-Current Tests on High-Tension Switchgear

BY PHILIP TORCHIO

Chief Electrical Engineer, New York Edison Co.

The article describes a series of tests on oil circuit breakers and disconnecting switches to determine their strength at brush contacts and supports in withstanding the mechanical stresses engendered by the magnetic flux due to the flow of large currents of the order of 100,000 amperes, as may exist at times of short circuits on large systems. Other tests were made on current transformers and potential transformer fuses.

For the first time, a synchronized motion picture machine and an oscillograph, were coupled to reproduce the coincident actions of the apparatus tested, and the variations of voltage and current in the circuit. The tests proved that practically all the circuit breakers then on the market had the brush contact placed in the wrong position, creating arcing before the operating mechanism had sufficient time to perform its function. The tests emphasized the importance of strong locks for disconnecting switches. Only single-turn primary-type current transformers and potential transformer fuses with resistance in series, were found adequate to give the service requirements.

THE high-current tests on oil circuit breakers, disconnecting switches, current transformers, and potential transformer fuses were carried out in 1918 and 1919 by the engineers and the Photographic Bureau of The New York Edison Company. The manufacturing companies lent effective cooperation in arranging the apparatus for the test, and in analyzing the results. For the first time, a synchronized motion picture machine and an oscillograph were coupled to reproduce the coincident actions of the apparatus tested and the variations of voltage and current in the circuit.

Oil Circuit Breakers

In connection with the study of very high-current electric welding apparatus, certain phenomena took place on the ordinary type of brush contacts, which prompted an investigation and subsequent tests to determine what would happen on the circuit breakers used in our central stations when subjected to currents of the order of 100,000 amperes, as may exist at times of short circuits on large systems.

The phenomenon which was noted was the well-known fact that when current is flowing in a closed circuit, the magnetic field set up by the current will tend to expand the loop outward. Therefore, if a circuit breaker is designed with a loop circuit so arranged that the mechanical pull due to the magnetic flux is to open the contact, the switch will present a weakness at that point; while if the movable contact parts are inverted so that the mechanical pull due to the magnetic flux is to force them more solidly against the fixed parts, the contact will be improved.

The circuit breakers tested were the *K*-52, *H*-3 and *H*-6 of the General Electric Company; and the *E*-9 and *O*-1 of the Westinghouse Electric & Manufacturing Company.

The tests proved that practically all the circuit breakers then on the market had the brush contact placed in the wrong position, so that when the current flowed the resultant mechanical force acted in a direction opposed to the brush pressure, thus tending to open the contact at this point; whereas, if the position of the contact brushes had been reversed, the mechanical force due to this current would have been exerted in the same direction as the brush pressure, thereby tending to improve the contact.

In addition to the force exerted at the contacts, it was found that the repelling force between contact supports was of such magnitude as to distort, and in some cases permanently displace, these parts.

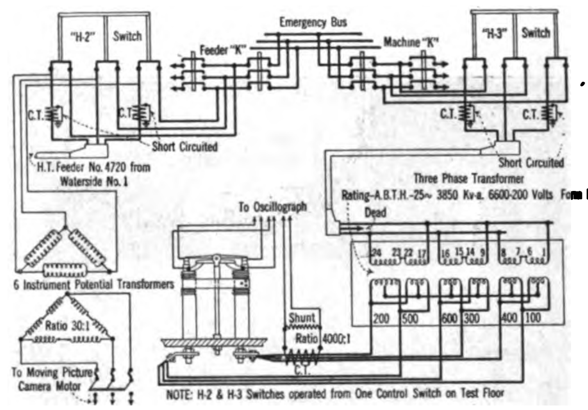

FIG. 3—DIAGRAM OF CONNECTIONS FOR TESTS

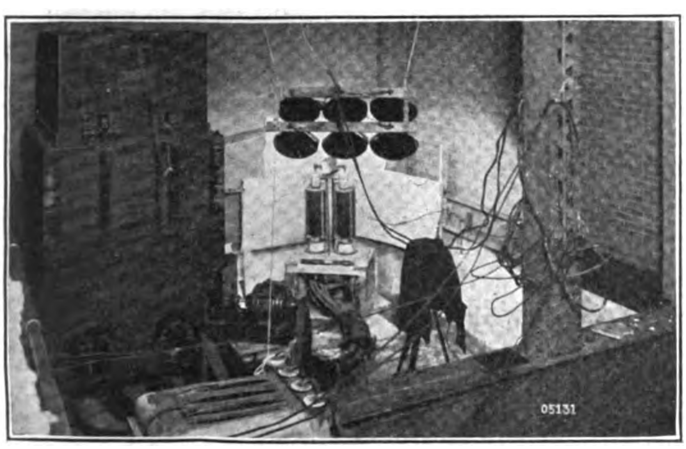

FIG. 4—SET-UP OF APPARATUS FOR TESTS

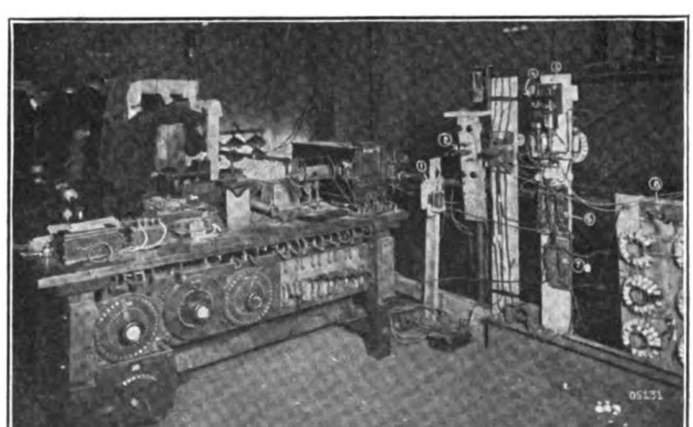

FIG. 5—CONTROL APPARATUS FOR TESTS; MOUNTED ON GALLERY ABOVE THE TEST FLOOR

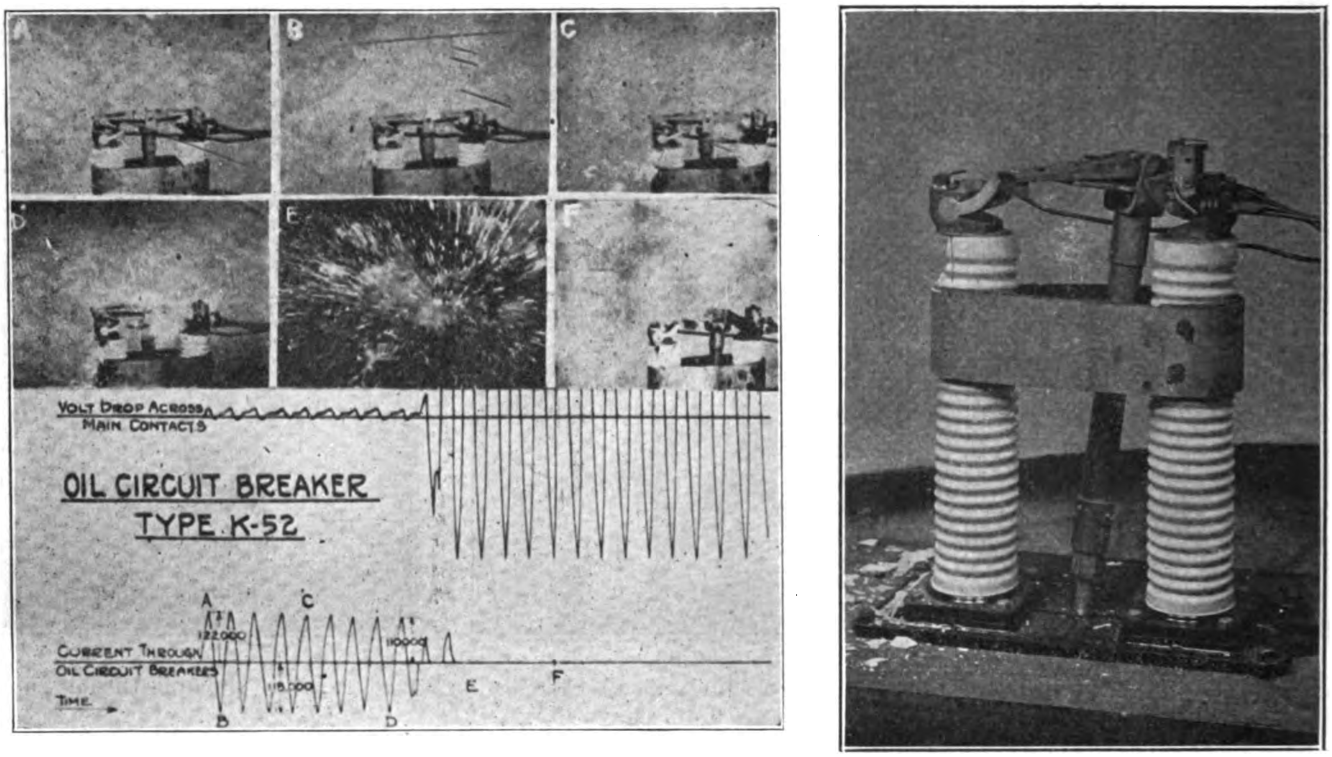

Fig. 6—G. E. Co. K-52 Circuit Breaker Reinforced With Fiber Band

Rating. 125,000 kv-a., 31,500 amperes at 2300 volts.

This circuit breaker was first tested at 27,000 and at 31,000 amperes mean effective which it withstood satisfactorily. It was then given 85,000 amperes mean effective which spread the porcelain pillars, breaking one at the special support, and twisted the movable contact around and entirely off the stationary contacts. Open-circuited at the 9th cycle.

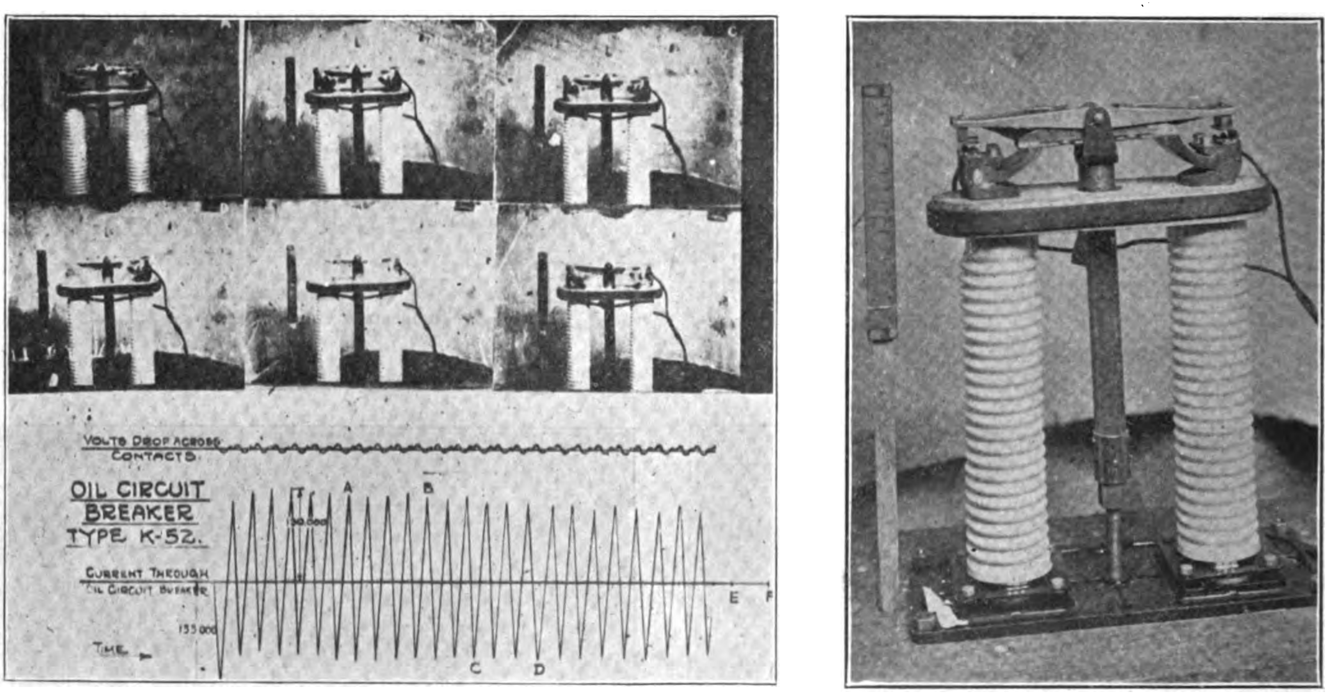

Fig. 7—G. E. Co. K-52 Circuit Breaker Reinforced With Wood and Steel

Rating 125,000 kv-a., 31,500 amperes at 2300 volts.

First withstood a test of 67,000 amperes mean effective. On 98,000 amperes mean effective the porcelain broke at 12th cycle. Slight arcing. Total spread of contacts approximately 3/16 in.

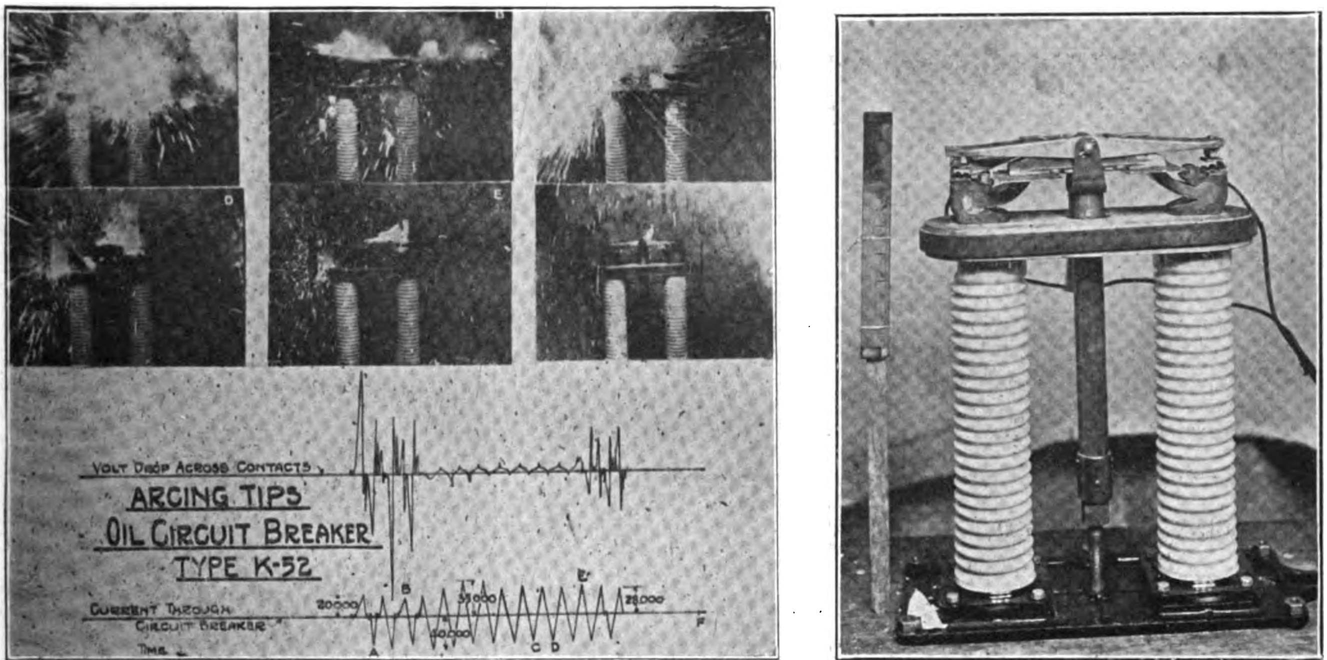

FIG. 8—G. E. CO. K-52 CIRCUIT BREAKER

Test on arcing tips only. Tested at 21,000 amperes mean effective. Contacts lifted on first ½ cycle, and for three consecutive cycles. Remained closed for seven cycles, and again opened for three cycles. Severe burning.

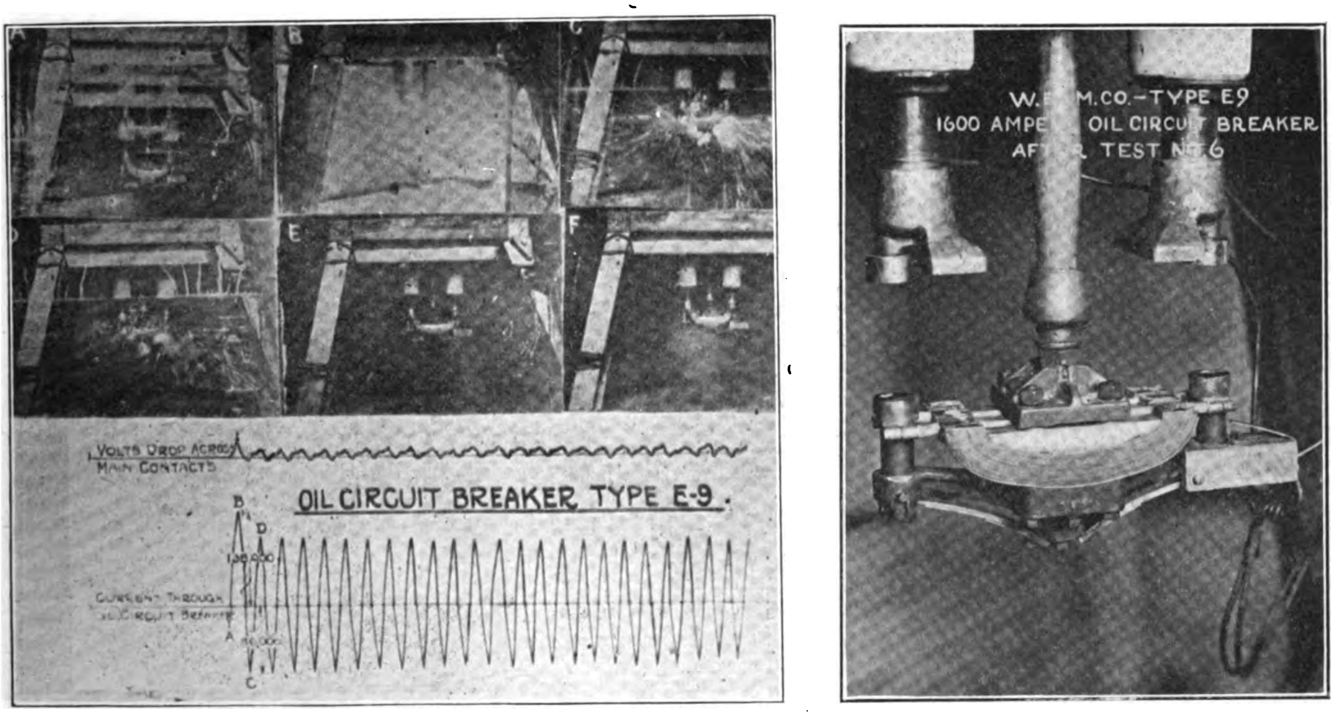

FIG. 9—WESTINGHOUSE E-9 CIRCUIT BREAKER

Rating 160,000 kv-a., 40,000 amperes at 2300 volts.
Tested at 79,000 amperes mean effective. Brushes lifted on first ½ cycle, arced and froze. Total spreading of contacts approximately 5/32 in.

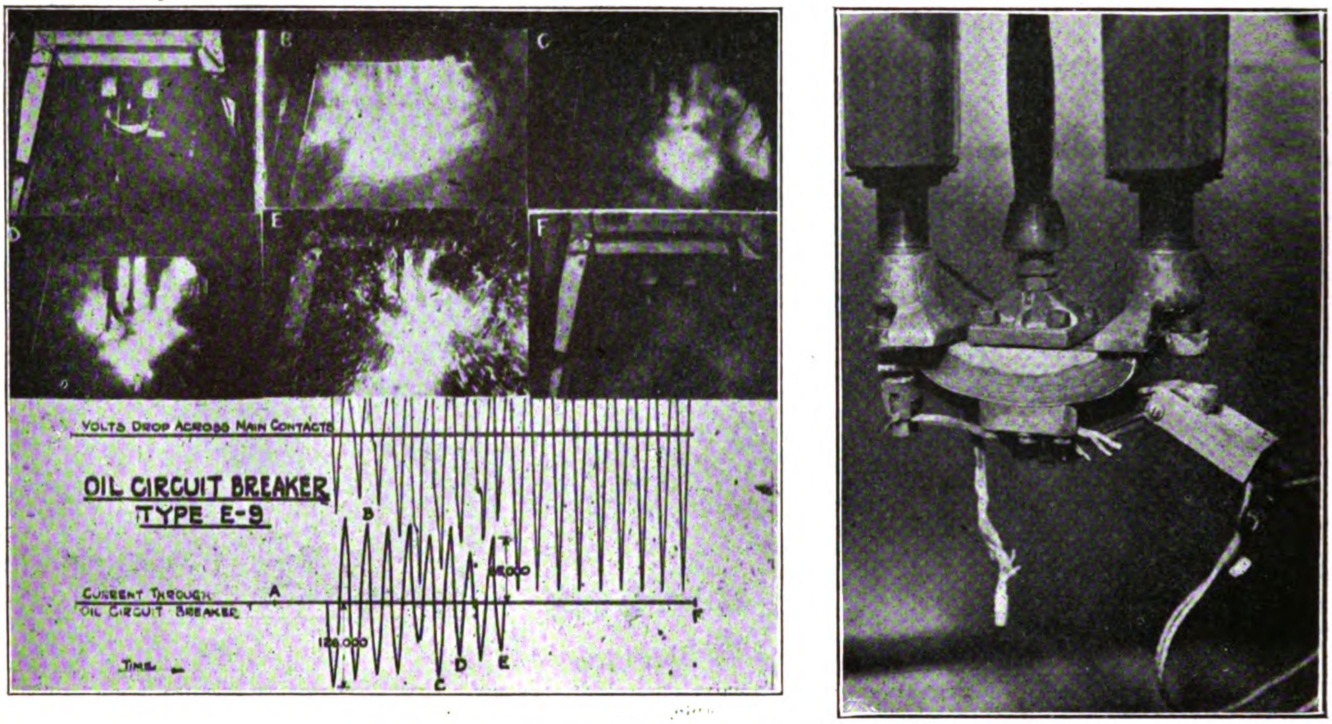

FIG. 10—WESTINGHOUSE E-9 CIRCUIT BREAKER

Rating 160,000 kv-a., 40,000 amperes at 2300 volts.
Tested at 89,000 amperes mean effective. Brushes lifted on first ½ cycle and burned clear at 8½ cycles.

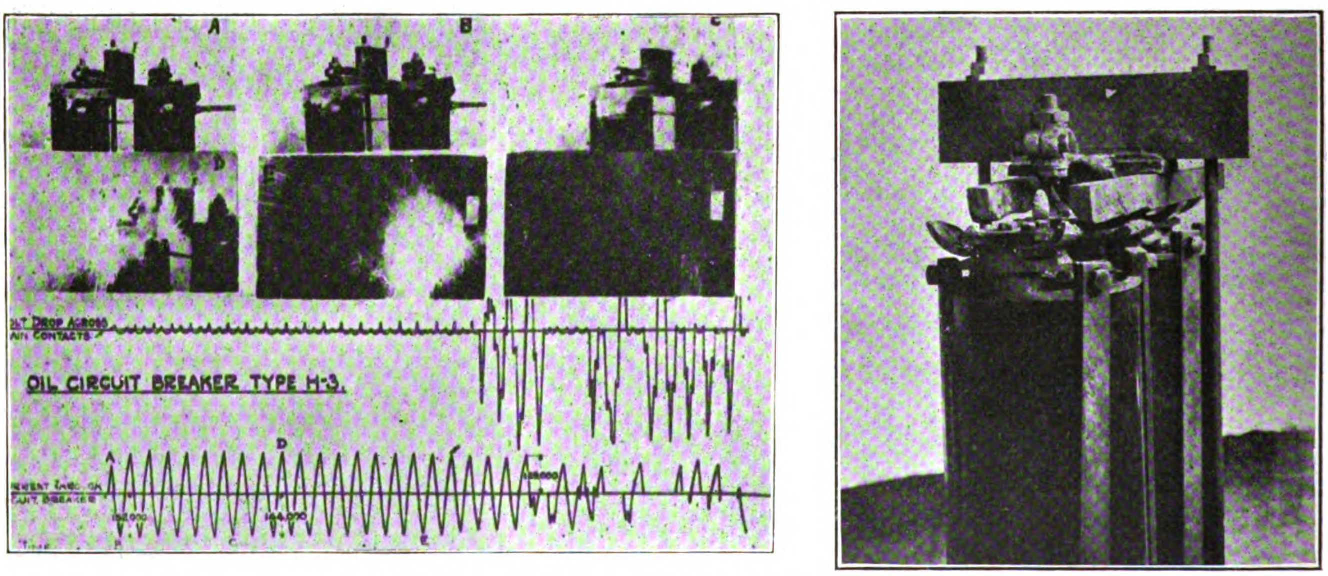

FIG. 11—G. E. CO. H-3 WITH INVERTED BRUSHES

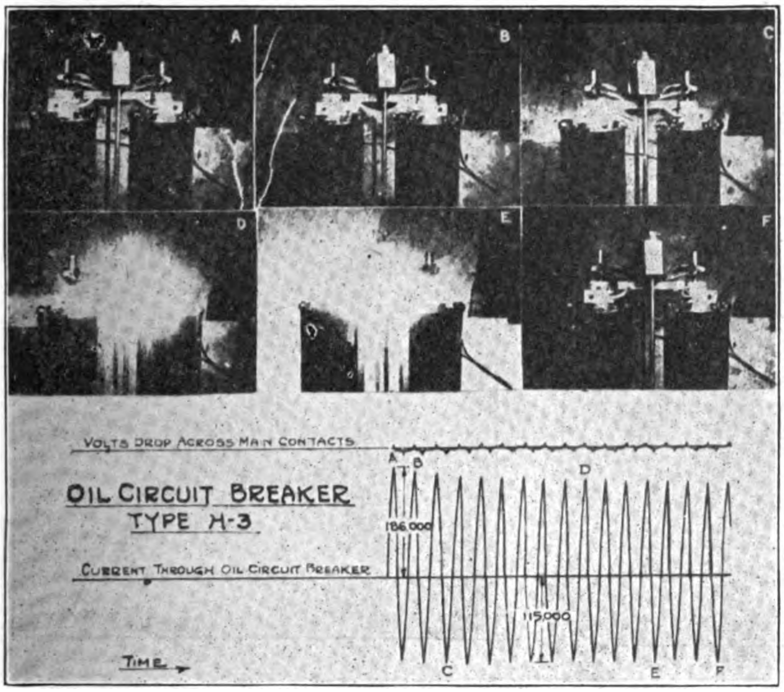
Rating 225,000 kv-a., 63,000 amperes at 2300 volts.
Tested at 103,000 amperes mean effective. Slight arcing at contacts due to vibration and spreading of pots, contact plates collapsed, one of the brass rods burned off, and switch open-circuited.



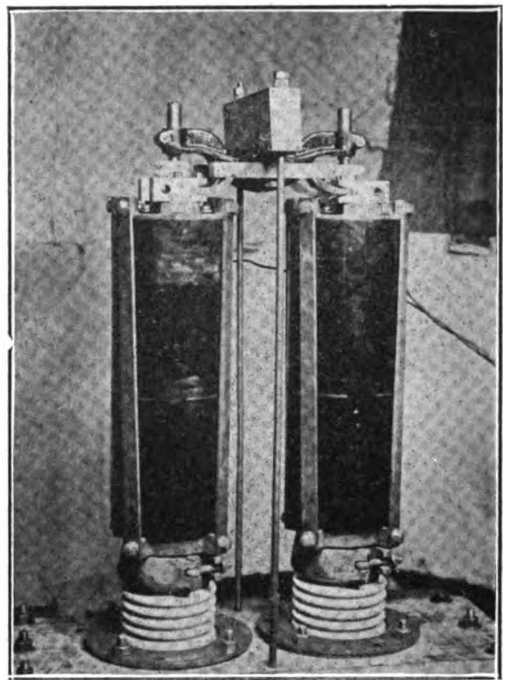


Fig. 12—G. E. Co. H-3 With Trial Brushes

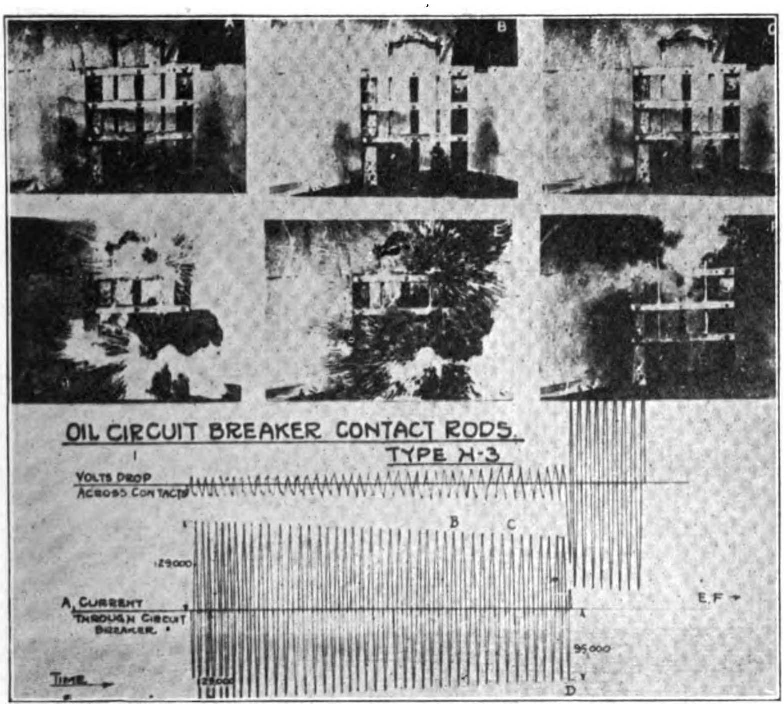
Rating 225,000 kv-a., 63,000 amperes at 2300 volts.

Tested at 112,000 amperes mean effective. Slight arcing at contacts due to vibration. One brass rod was bent. Total spreading of pots 1 1/8 in. The bright irregular lines at the left edge of Section B of the film are caused by static discharge due to the high speed at which the films were taken This appears in a number of the motion pictures, notably Section E of the film in Fig. 17.



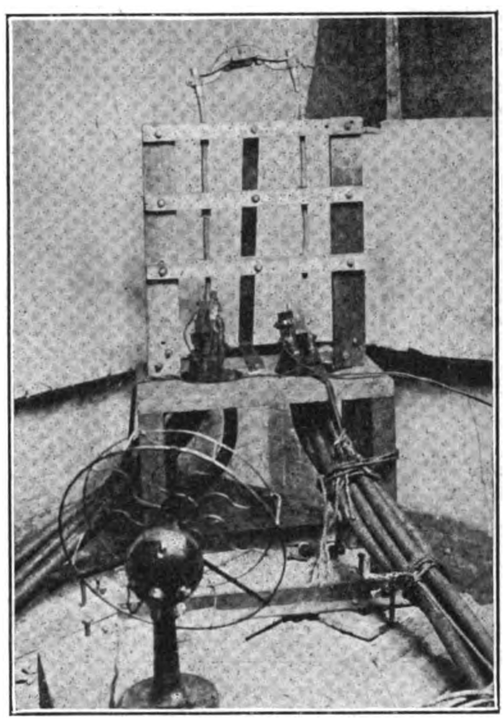


Fig. 13—G. E. Co. H-3 Contact Rods

Standard brass rods tested at 41,000 amperes mean effective, burned off at contact with crossarm in 0.57 sec. Copper rods tested at 91,000 amperes mean effective, burned off in body of rod in 1.8 sec. Copper rod test shown above. Note bending between supports.

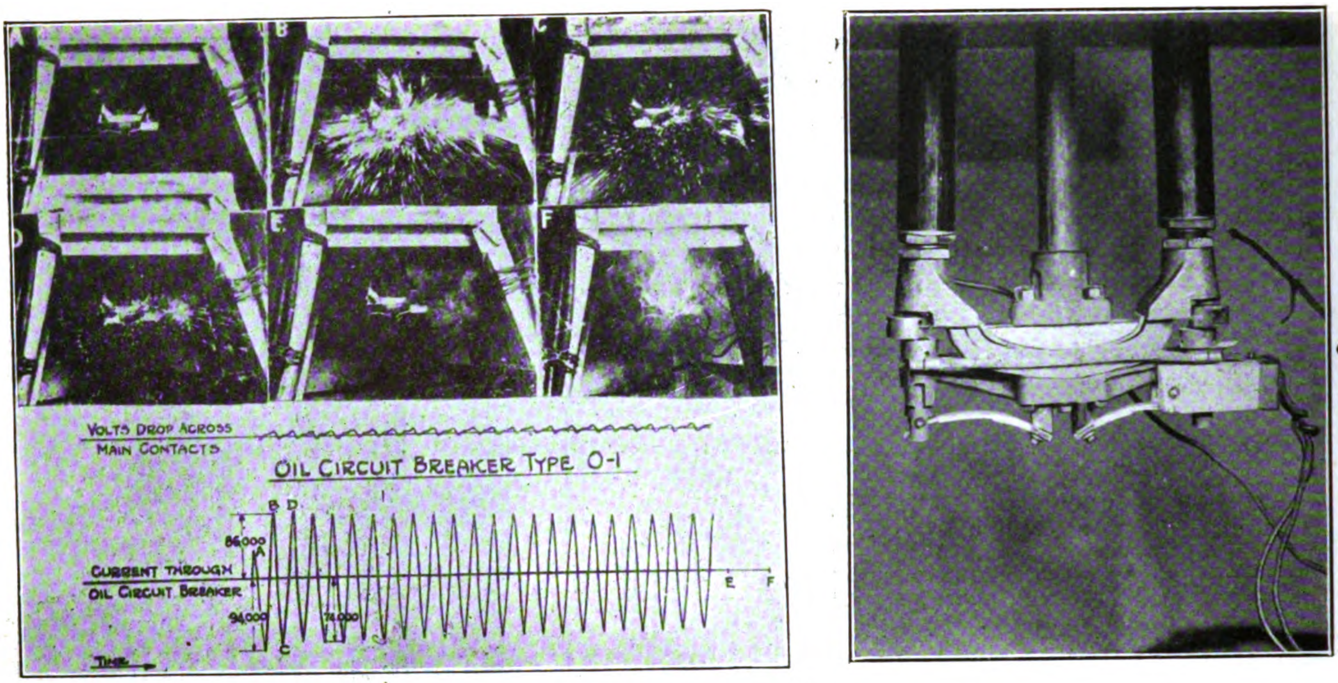

FIG. 14—WESTINGHOUSE O-1 CIRCUIT BREAKER

Rating 350,000 kv-a., 88,000 amperes at 2300 volts.

Tested at 63,000 amperes mean effective. Brushes lifted on first ½ cycle, froze and remained closed. Total spreading of supports approximately 3/16 in.

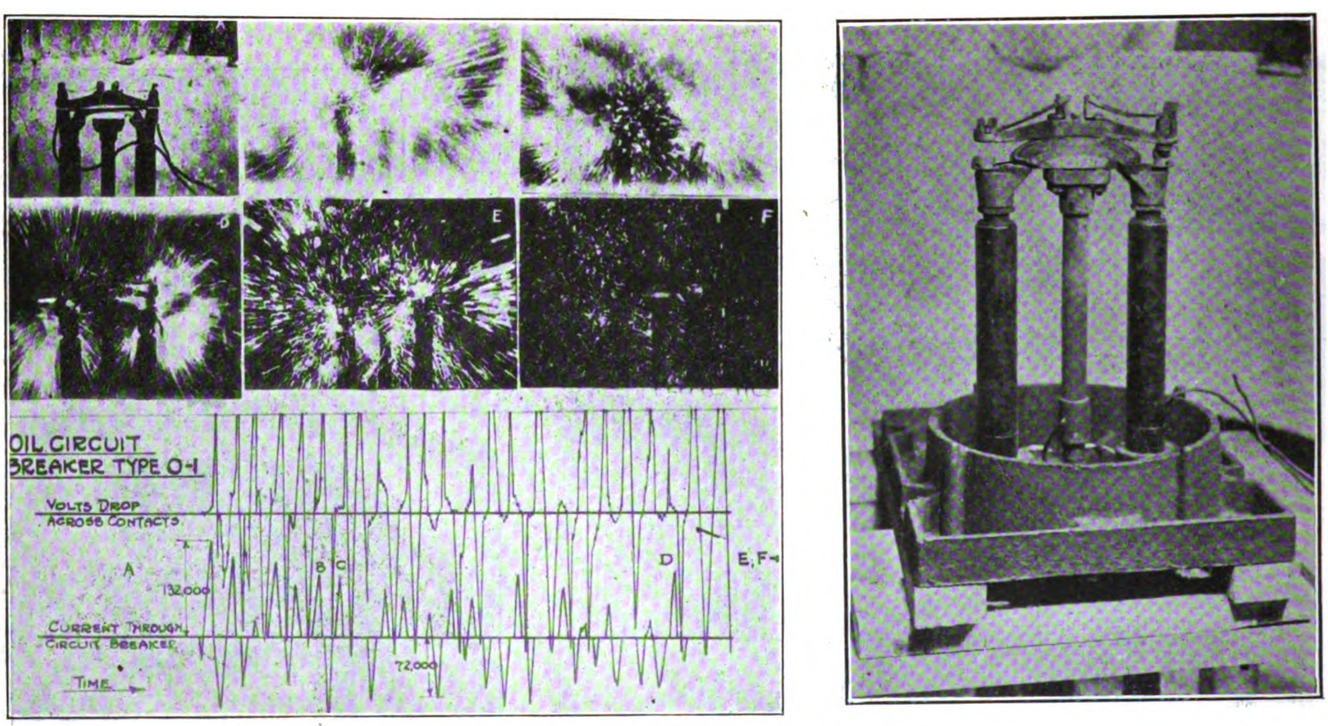

FIG. 15—WESTINGHOUSE O-1 CIRCUIT BREAKER

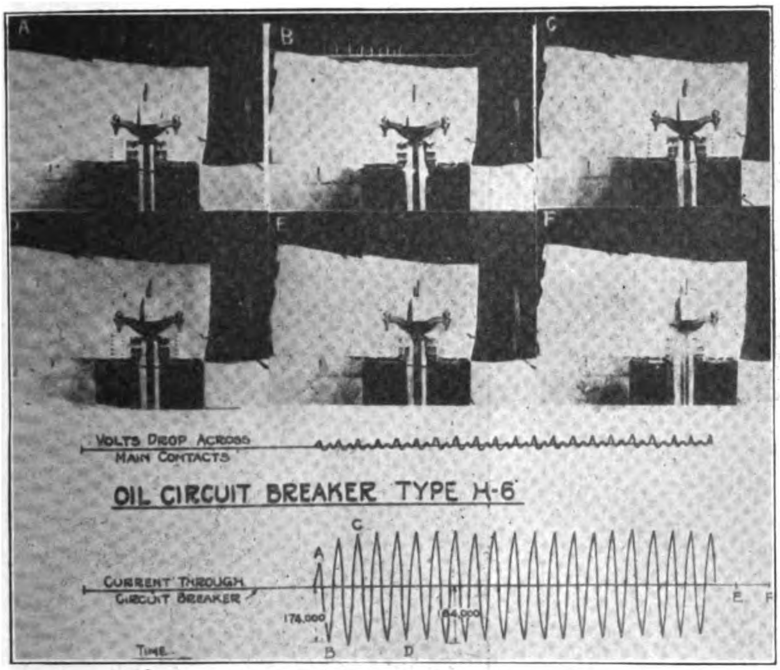
Rated at 350,000 kv-a., 88,000 amperes at 2300 volts.

Tested at 84,000 amperes mean effective. Brushes lifted on first ½ cycle and continued intermittently throughout test. Arcing tip destroyed. Considerable spreading of supports during test but no permanent spreading noticed.



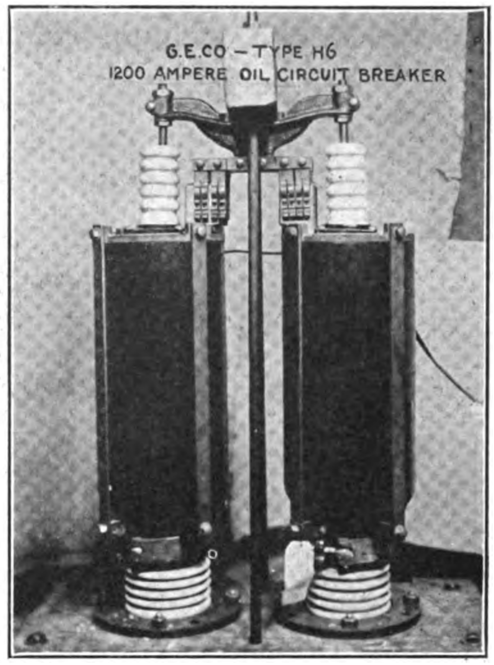


FIG. 16—G. E. CO. H-6 CIRCUIT BREAKER

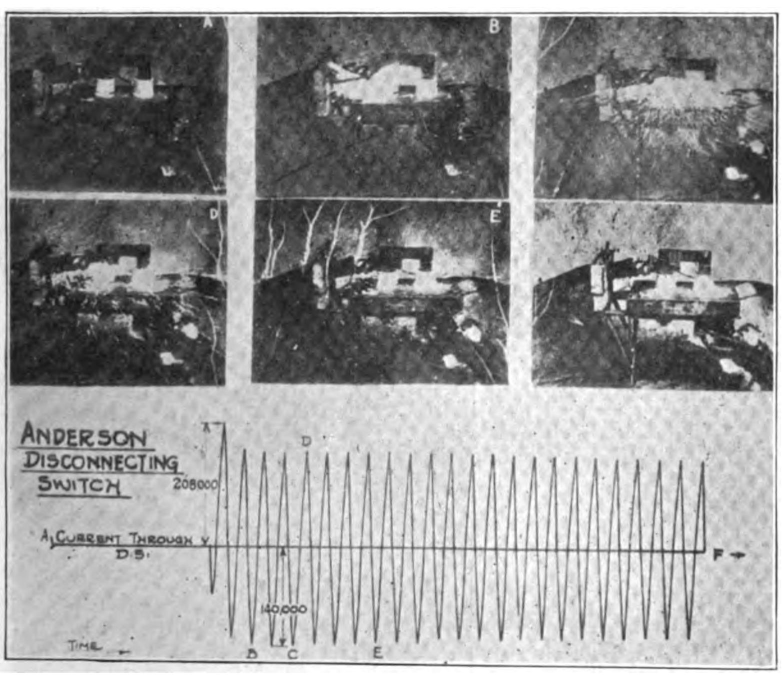
Rated at 350,000 kv-a., 88,000 amperes at 2300 volts.

Tested at 130,000 amperes mean effective. Pots spread at first ½ cycle, no arcing. Parallel paths through moving contact causes attraction of contact fingers and, therefore, tightening instead of opening of contacts. Total spreading of pots approximately one in.



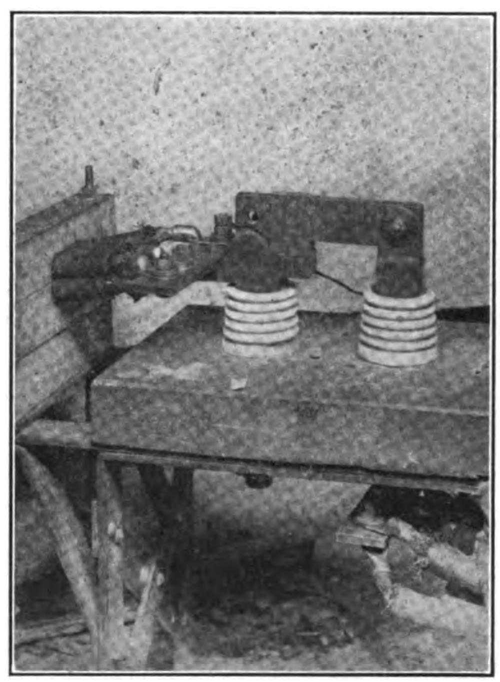


FIG. 17—ANDERSON DISCONNECTING SWITCH WITH SPECIAL LOCK

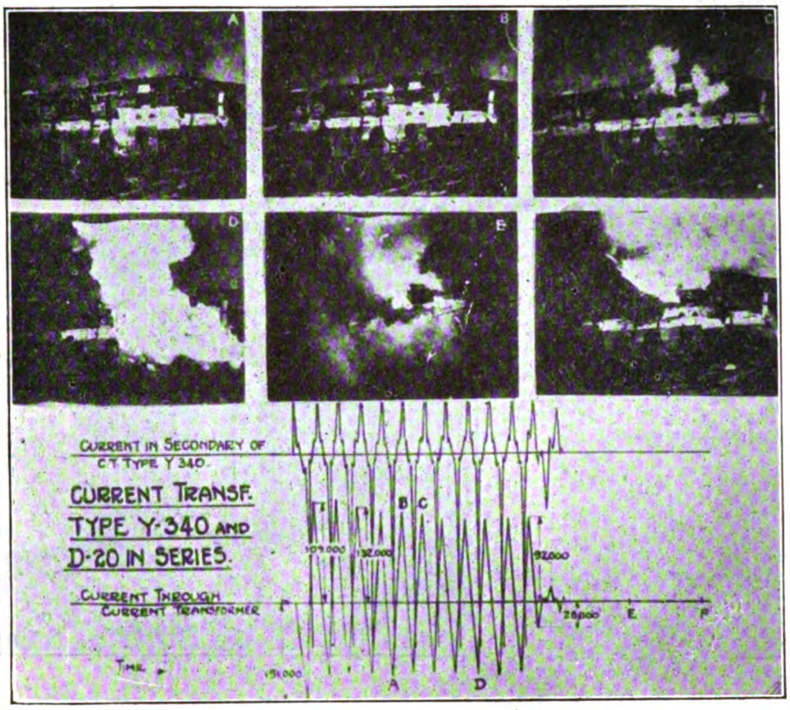
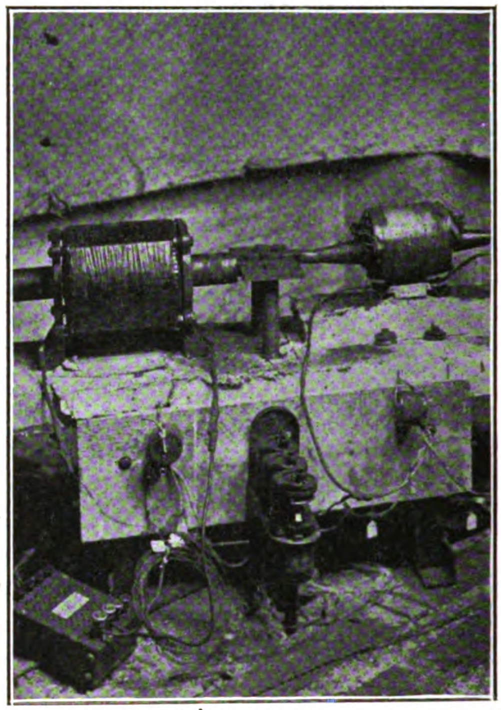
Tested at 130,000 amperes mean effective. Slight chipping of porcelain. No damage to switch. Arcing shown was due to poor contact at terminal.

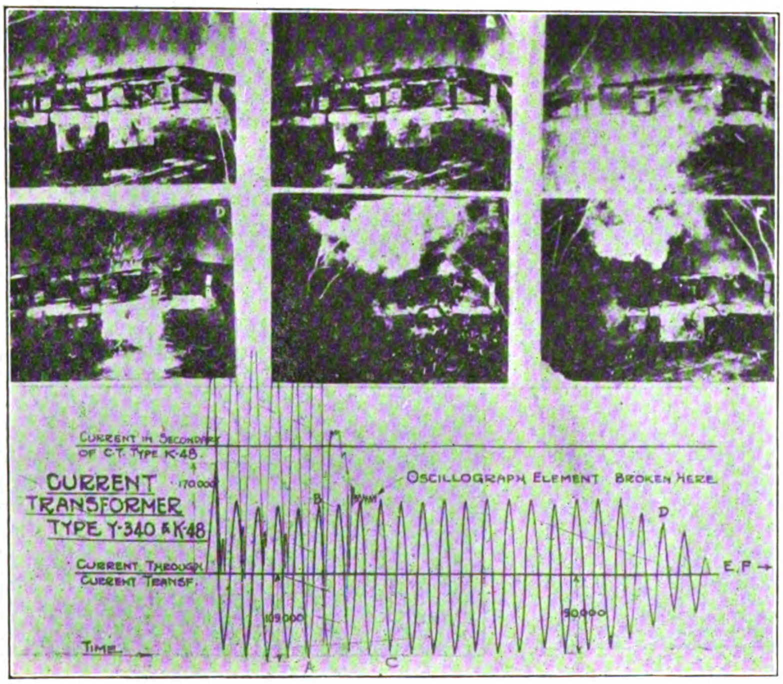


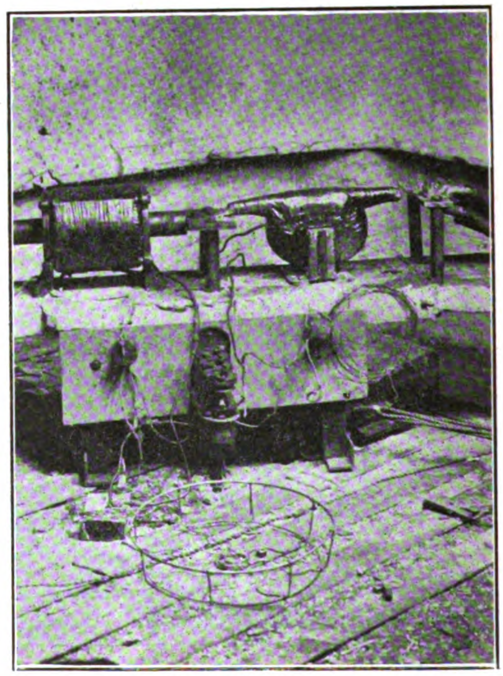


After test

Fig. 18—G. E. Co. Current Transformer Y-340 and D-20, Single-Turn.

Tested at 92,000 amperes mean effective. Primary of D-20 blew open after 12½ cycles. Secondary destroyed. Y-340 not injured. (D-20 is a superseded type).





After Test

Fig. 19—G. E. Co. Current Transformers. Y-340 and K-48 Single-Turn.

Tested at 101,000 amperes mean effective. Primary of K-48 opened after 23½ cycles, due to failure at terminal. Y-340 not injured.

the mechanical force resulting from the high current. This phenomenon occurs in practise before the operating mechanism has had sufficient time to perform its function in opening under short circuit.

On the basis of the results obtained, the manufacturers have revised the design of their circuit breakers so as to eliminate the trouble due to contact separation and displacements, as shown in Fig. 1 for General Electric Company apparatus, and in Fig. 2 for Westinghouse Company apparatus. Other detail improvements are referred to in the illustrations hereinafter given.

Testing Equipment

Current for the tests was supplied by two 10,000-kw. generators in Waterside station, operated in parallel

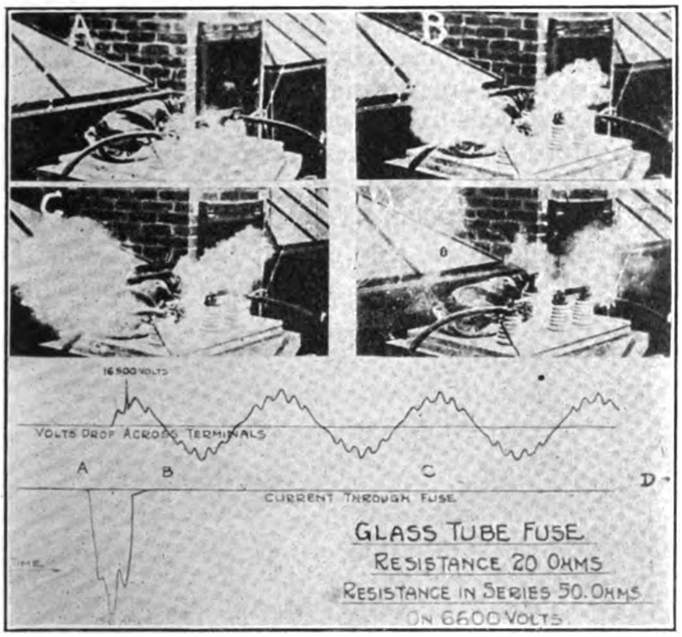


Fig. 20—Glass Tube Fuse of 20 Ohms Resistance With 50 Additional Ohms in Series.

Tested at 6600 volts. Mean effective 156 *amperes maximum*. Tube was unbroken but asbestos filler was expelled from both ends. Duration of current 0.27 cycle. Circuit opened successfully.

and connected through their reactors to an emergency bus. This bus was connected, through the tie bus reactors, to a second emergency bus to which a 350,000-cir. mil feeder was connected for supplying power for the tests at the West 41st Street substation. (See Fig. 3.)

At the substation, the feeder *H*-2 and the *H*-3 switch of a 3500-kw. synchronous converter were connected in series through their *K* switch and the emergency bus to the high-tension side of a 3850-kv-a., three-phase synchronous converter air-blast transformer. The control circuit of the two *H* switches was connected to operate from the control switch as a four-break unit. The three high-tension transformer windings were connected in multiple as a single-phase transformer. The six low-tension windings were similarly connected, giving 170 to 200 volts at full voltage.

The records of the test were made by oscillograph, and a motion picture camera was driven synchronously from the feeder supplying energy for the tests; also

a Lichtenberg high-speed camera was used. In addition, close-up pictures were made of each subject with the ordinary camera after each test.

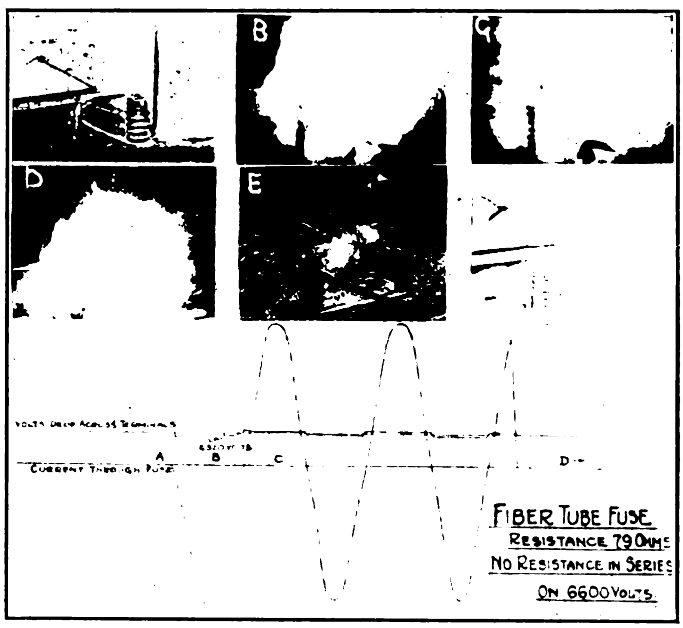

Fig. 22—Fiber Tube Fuse of 79 Ohms Resistance With no Additional Resistance in Series

Tested at 6600 volts mean effective 1970 *amperes maximum*. Fuse completely blown to pieces. Circuit opened manually. Duration of current 3.1 cycles.

The oscillograph had three vibrators, one of which was used to measure the secondary current in the type *E*-3 General Electric Company current transformer,

20,000-ampere, 4000 to 1 ratio. The second vibrator was used to measure the voltage drop across the brush contacts. The third vibrator was used to give a 25-cycle timing wave from the Waterside main bus, ex-

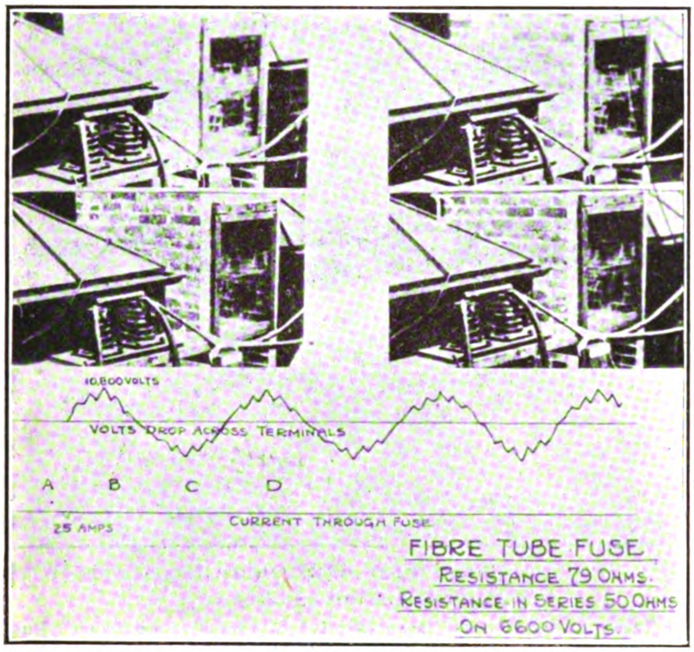

FIG. 23—FIBER TUBE FUSE OF 79 OHMS RESISTANCE WITH 50 OHMS ADDITIONAL IN SERIES

Tested at 6600 volts mean effective, 25 *amperes maximum*. Fuse opened the circuit without visible disturbance. Duration of current 0.02 cycle.

cepting in tests of circuit breakers having auxiliary arcing tips. On circuit breakers so equipped the third vibrator was connected to give an alternating wave only when the auxiliary contact was lifted 1/32 inch or more. For some of the tests, the third vibrator was connected to measure the current on the primary side of the testing transformer. The oscillograph was calibrated immediately before and after the tests.

The motion pictures were made by a standard Moye camera, gear-driven, from a ½-h. p. synchronous motor. The calibration was accomplished by photographing an ordinary arc lamp operating on 25 cycles from the same source which drove the motor, and adjusting the shutter so that the full opening occurred at the point of greatest brilliancy in the arc.

The camera was started and brought to synchronous speed before the test current was applied to the subject. The camera operation was continued synchronously until after the test current was interrupted. Two pictures were taken during each cycle, adjacent pictures therefore, showing events at a time interval corresponding to 180 electrical degrees, or one-fiftieth of one second. The camera shutter design was such that the exposure for each picture lasted during about 60 electrical degrees. Figs. 4 and 5 show the apparatus.

The Lichtenberg camera was equipped with a lens board and 24 lenses arranged to give successive exposures. It was set to take its 24 pictures during the first two cycles of the test current. As the tests progressed, however, the time of exposure was increased somewhat to obtain better negatives. Although these pictures were, in general, a success, they are not shown herein, as the motion pictures, being in synchronism with the oscillograph records, more adequately illustrate the results obtained.

RESULTS OF TESTS

From all the records, in Figs. 6 to 16 inclusive, are combined characteristic results of motion pictures and oscillographs for the apparatus tested.

DISCONNECTING SWITCHES

The same mechanical stresses caused by flow of high currents, as reviewed in the paragraph on oil circuit breakers, apply, to a large extent, to the design of disconnecting switches. The ideal installation would be a straight disconnecting switch in series with the main circuit without bends. When, however, bends are necessary, the blade opening should be at right angle to the main lead. In addition, suitable strong locking devices are to be provided. See Fig. 17.

CURRENT TRANSFORMERS

In large systems, only current transformers of the single-turn, primary type are capable of withstanding

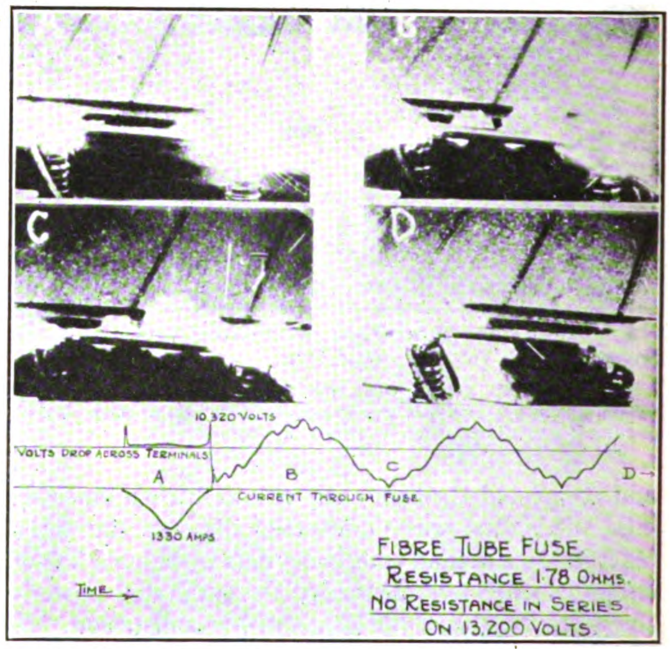

FIG. 24—FIBER TUBE FUSE OF 1.78 OHMS RESISTANCE WITH NO ADDITIONAL RESISTANCE IN SERIES

Tested at 13,000 volts mean effective, 1330 *amperes maximum*. Fuse blew out end of caps but opened the circuit. Duration of current 0.54 cycle.

short circuits as may occur on the system. The other current transformers are too weak, and will be either ruptured mechanically or destroyed thermally. See Figs. 18 and 19.

POTENTIAL TRANSFORMER FUSES

Extensive tests were made with and without resistance in series. The tests have conclusively proved

that no type of potential fuse on the market can satisfactorily open the circuit without a resistance in series. The company first used a resistance wire wound spirally on a rope core and insulated suitably for the voltage on which it was applied.

Recently, the suggestion has been made to use an asbestos card with a resistance wire wound on it in series with the fuse. Where space does not permit the use of the high-resistance lead, this substitute may be of advantage. See Figs. 20 to 24, inclusive.

The Maximum Safe Operating Temperature of Low-Voltage Paper-Insulated Cables

BY W. A. DEL MAR
Chief Engineer, Habirshaw Electric Cable Co.

The Standards of the Institute state that for low-voltage cables the maximum safe operating temperature is 85 deg. cent. Experiments show that continuous operation at 100 deg. cent. for less than a month, seriously impairs the mechanical condition of impregnated paper. A standard of permissible mechanical condition should, therefore, be established, if such high temperatures are to be allowed. Operation at higher temperatures than allowed by the present Standards is, however, in the nature of a gamble and it is questionable whether the Standards should take cognizance of it.

Statement of the Problem

NOTHING would seem more simple than to determine the maximum safe operating temperature of an insulating material such as impregnated paper; but the problem is really very complicated as several preliminary problems of an important character must be settled before the main problem can be adequately attacked. These preliminary problems are as follows:

1. What is the criterion of quality of paper insulation by which we may say whether it is satisfactory for service?
2. What is the effect of the continued application of various degrees of heat, expressed in terms of the criterion selected?
3. Will intermittent heat have the same effect as continuous heat provided the aggregate time of exposure and the temperature are the same in both cases?
4. If the above questions should be satisfactorily answered, what form of rule should be adopted so as to make the best economic use of the information thus obtained?
5. If a rational rule for the maximum permissible temperature of paper insulation should be developed, how can the hottest-spot temperature of a cable in a duct be measured in order to ensure that the cable is working within the rule?

These questions cannot all be answered at the present time, and the object of this group of papers is to gather together such data as are available in order that the Standards Committee of the Institute may be able to revise its present rule for the temperature limits of paper insulation in the light of the best information which the members of the Institute can furnish.

To be presented at the 9th Midwinter Convention of the A.I. E. E., February 16-18, 1921.

Criterion of Quality

In the case of low-voltage cables, which are the only ones under present consideration, the criterion of quality by which we may judge whether the cable is usable, should be the mechanical strength, because it is that quality which determines whether the cable can withstand handling, expansion and contraction, and possible reinstallation. New cables of the best quality have but little margin of strength to take care of the stresses imposed on the insulation during installation. Large cables are often installed in splicing chambers originally designed for small cables, and are consequently bent on curves of dangerously small radius, and are subjected to very rough handling. Even where splicing chambers are adequately designed, the cables are often handled with entire disregard of their mechanical limitations. However, once the cables are installed, they are free from mechanical stresses except such as may result from expansion and contraction due to variations of temperature. A different criterion of quality may therefore conceivably be adopted for cables after they are installed from that for new cables, but the use of such a standard would preclude the possibility of reinstalling cables which have deteriorated to that standard.

Some cable specifications contain clauses requiring the paper to have a certain minimum tensile strength, but tensile strength tests are unsatisfactory because the paper may become brittle, and may tear easily, while the tensile strength remains quite high.

Bursting strength tests, as made on a Mullen tester, are unsatisfactory for the same reason. A test, which proved to be really satisfactory, is the tearing test. A piece of paper about three centimeters wide is carefully cut with a razor along its center line from one end to about its center, and a pencil mark made one centimeter beyond, as shown in Fig. 1. It is then suspended

from one of the small ends as shown in Fig. 2, and a balance pan attached to the small free end, the large end being allowed to swing free. Sand is then poured continuously into the pan until the paper begins to tear. The stream of sand is then continued slowly, stopping if the paper continues to tear, but proceeding if the tearing stops. It is continued until the tear reaches the centimeter mark. The total weight of pan and sand expressed in grams is taken as the tearing strength of the paper. The reason for letting the paper tear a definite amount, rather than to observe the weight at which the paper begins to tear, is that paper varies in thickness and condition from place to place, and the initial tear would only represent the strength at a spot and would not be a measure of the average

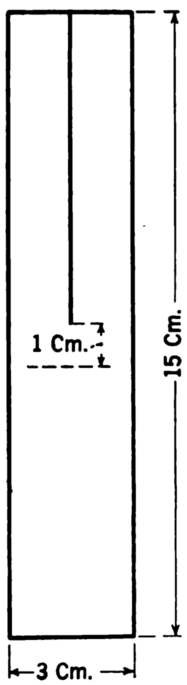

FIG. 1—SAMPLE FOR TEARING TEST

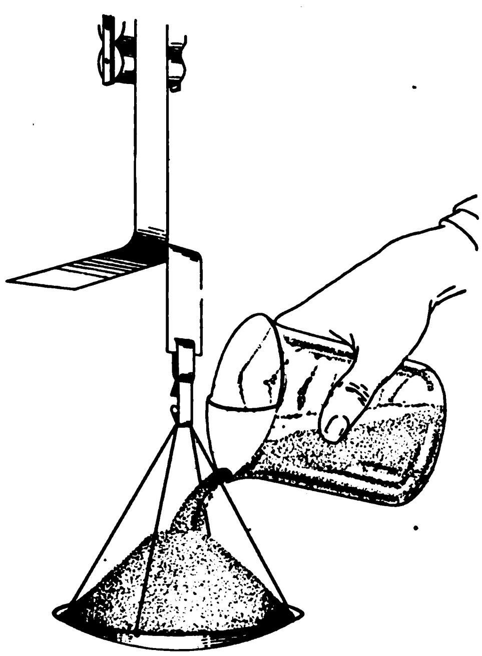

FIG. 2—TEARING TEST

quality. The tearing strength of unimpregnated Manila rope paper 0.02 mm. (8 mils) thick, under ordinary conditions is from 170 to 285 grams (6 to 10 oz.) When impregnated, the tearing strength is usually less than this, depending upon the nature of the impregnating compound, the temperature and duration of the process of impregnation and the amount of the compound retained upon cooling. Manila rope paper usually contains from 5 to 10 per cent of moisture. Tests were made to ascertain whether the percentage of moisture had any effect upon the tearing strength. The results are shown in Fig. 3, which shows that an increase of moisture increases the tearing strength up to a certain point and decreases it above that point. Statements of tearing strength are, therefore, not complete unless the moisture content is specified.

Tests to ascertain the effect of the continued application of various degrees of heat may be made either with samples of finished cable or with samples of paper immersed in compound. A preliminary test was made to ascertain whether these two kinds of tests give the same results. It would be difficult to make direct observations to prove this point owing to the impossibility of being sure that the cable and the separate samples of paper were both subjected to the same heat and mechanical treatment prior to the test. Resort was therefore had to an indirect test. A beaker of hot

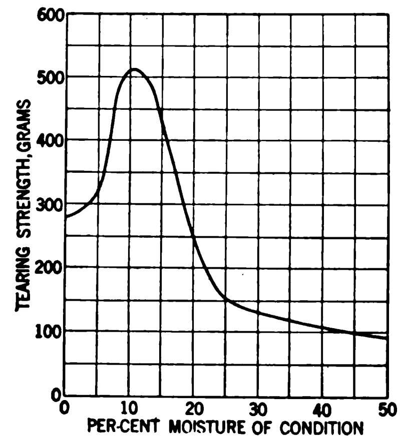

FIG. 3—EFFECT OF MOISTURE ON TEARING STRENGTH OF UNIMPREGNATED PAPER

petrolatum compound was dried in vacuo at 135 deg. cent. until all the volatile matter was driven off, and was then exposed to air at the same temperature for three hours. It was found that no increase in weight occurred, indicating that there was no oxidation. If the paper is wound in rolls similar to cable insulation and immersed in beakers of impregnating compound, the actual conditions in a cable should be closely simulated.

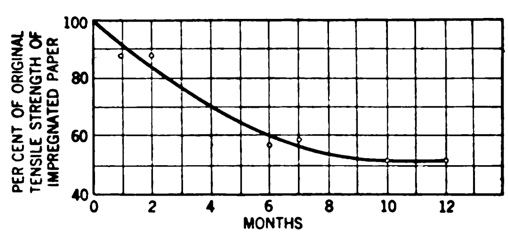

FIG. 4—LOSS OF TENSILE STRENGTH OF IMPREGNATED PAPER IN PETROLATUM-RESIN COMPOUND AT 85-90 DEG. CENT.

EFFECT OF CONTINUOUS HEATING

Tests were made upon rolls of paper immersed in open beakers of petrolatum-resin compound maintained between 85 and 90 deg. cent. for a year. These tests were made before the development of the tearing test and the results are therefore expressed in terms of tensile strength. The gradual loss of strength is shown in Fig. 4, which shows that at the end of a year, the paper had lost about half the tensile strength it possessed just after impregnation. It is probable, that the tearing strength would have been even more reduced. The paper, however, was in quite good enough condition at the end of a year for new low-voltage cables.

Tests were made upon unimpregnated paper with the object of determining the behavior of Manila rope paper exposed to high temperatures. Samples of paper were heated in vacuo successively at 70 deg., 80 deg., 90 deg., 100 deg., 110 deg., 120 deg., 130 deg., 140 deg., 150 deg., and 160 deg. cent., the temperature of all samples being maintained at each of these points for as many periods of one hour as were required to ensure that constant weight was obtained. The average results are shown in Fig. 5 which indicates that the loss in weight increases slowly up to about 120 deg. cent., but then rises rapidly. At 130 deg. cent. oily globules distil off; at 140 deg. cent. the paper darkens, indicating charring. The loss of weight which occurs above 120 deg. cent. is not necessarily due to loss of moisture. However, some of the material which distills off is undoubtedly moisture, but this may be due to the decomposition of the cellulose, which is a carbohydrate having a composition of $(C_6H_{10}O_5)_x$, which may, therefore, be reasonably expected to yield water among its products of decomposition.

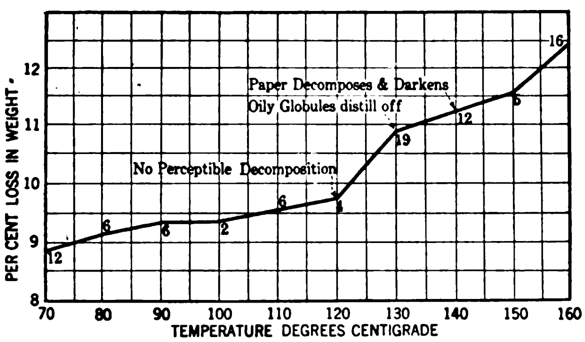

Fig. 5—Unimpregnated Paper

The figures at each point of the curve represent the number of hours of heating at each temperature before proceeding to the next. A steady weight was reached in about one hour less than these periods.

Another series of tests was made by putting a roll of dried paper in a beaker of petrolatum-resin compound for three hours and noting the loss in tearing strength. This test was made on a separate roll for each of six temperatures from 70 to 140 deg. cent. The results are shown in Fig. 6 and indicate the degree that impregnated paper may be injured by three hours exposure to the temperatures covered by these tests. As in the year test at 85-90 deg. cent. the paper in any of these rolls was in good enough condition for new low-voltage cables.

The most decisive series of tests was made on sealed lead-sheathed cables placed in an electric oven maintained carefully at a temperature of 100 deg. cent. The temperature was measured by three thermometers, one above, one below the samples, and one fastened to a cable sheath under a felt pad. The reading of the upper thermometer was about 99 deg. cent. and the under thermometer about 101 deg. cent. The thermometer on the cable sheath read a fraction of a degree below the mean air temperature in the oven. The mean temperature was kept constant by a calibrated thermostat, the maximum variation being 1½ degrees above or below the mean. At the end of a week, one sample of cable was removed and its paper tested for tearing strength and tensile strength. About 6 pieces of paper were taken for each test, and the results being substantially uniform, a mean was taken for the tearing strength and one for the tensile strength. This test was repeated at the end of 2, 3 and 4 weeks. After the fourth week, the paper had

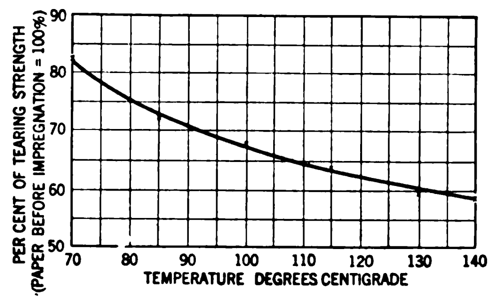

Fig. 6—Effect of Heating Paper in a Beaker of Petrolatum-Resin Compound for Three Hours

A special sample was used for each point.

become so brittle that it cracked apart when folded. The results of the test are shown in Fig. 7, and they indicate that the mechanical strength of paper insulated cables is destroyed by *continuous* exposure to a temperature of 100 deg. cent. for three or four weeks.

As the insulation was intact before the samples were opened at the end of a month, and as they were thoroughly dry, the electrical properties of the cable were undoubtedly quite good enough for low-voltage operation, provided it was not disturbed.

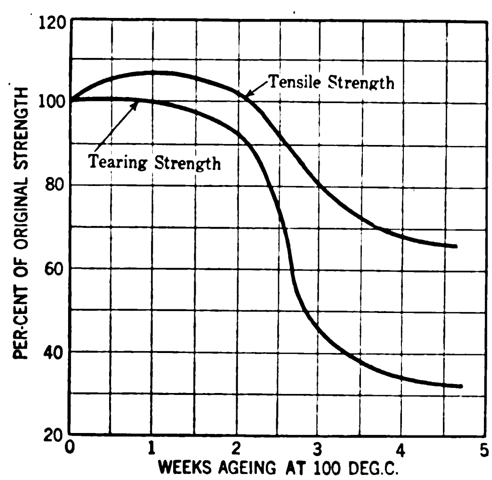

Fig. 7

Distribution systems may therefore be in satisfactory operation with cables in the condition of these samples, but the risk of operating them in this condition is obviously greater than with the insulation in good mechanical condition.

Intermittent Operation

A test to give the same aggregate exposure to heat as in the test described above would last 8 months

if the cable were heated for 3 hours every day. Such a test is under way, but the results will not be available in time for the Convention. If intermittent heat has any less effect than continuous heat of the same aggregate duration, it must be because paper recovers some of its strength during the low-temperature portions of the heat cycle. Tests on numerous samples of heat-injured paper failed to show such recovery.

Form of Rule for Maximum Temperature

The present Standards of the American Institute of Electrical Engineers give 85 deg. cent. as the maximum permissible temperature of impregnated paper insulation for low-voltage cables. The following table shows the increase in carrying capacity that would result from operation at higher temperatures, assuming 40 deg. cent. duct temperature.

Ultimate temperature deg. cent.	Increase of carrying capacity over that for 85 deg. cent. ultimate temperature, per cent.
85	0
90	5
95	9
100	13
105	17

This increase of carrying capacity may sometimes warrant the use of cables at destructive temperatures, and the operating engineers may rightly consider such a procedure to be entirely justified. It is questionable, however, whether the Institute should make a rule to cover such cases, as an Institute rule necessarily represents an agreement between manufacturer and user and it is unreasonable to expect the manufacturer to share the risks resulting from operation at or beyond the limit of endurance of his product.

Use of a Rule for Maximum Temperature

Assuming all of the above problems to be satisfactorily answered, we would still be confronted by the difficulty of applying our knowledge to practical operating conditions, because it is almost impossible to ascertain accurately the hottest-spot temperature of a cable in a duct. This problem is complicated by the presence of other cables in neighboring ducts and by the variable thermal resistivity of the soil. The Cable Research Committee of the National Electric Light Association is giving serious attention to this problem.

The present interest in this subject arises from the increased loads which war conditions suddenly imposed on the central stations and the consequent enforced operation of cables at higher temperatures than were previously thought safe. The experience of the central station men indicates that low-voltage cables may be operated at higher temperatures than were considered safe a few years ago. Whether this experience should be the basis of a modification of the existing rule, is a matter for debate.

It is to be hoped that the operating experience of the central station men will be satisfactorily correlated with the laboratory work of the manufacturers before a new standard is established.

CONDITION OF ELECTRIC RAILWAY INDUSTRY

P. H. Gadsden, President of the American Electric Railway Association, gives the following statement regarding the condition of the electric railway industry:

An official report on the national condition of the electric railway industry for the year ending January 1, 1921, just compiled by the American Electric Railway Association, indicates a gradual and steady approach to a stable basis.

This situation is largely due to the fact that regulatory bodies, recognizing that granting of the claims of electric railways for fair rates of return is essential to the maintenance of good service, have steadily ordered relief throughout the country.

These regulatory bodies also seem to be cognizant of the fact that rehabilitation of lines will be a slow process and that at least the present advanced rates must be maintained for some time even if falling costs, anticipated but not realized as yet, should come. A large majority of the companies in the last four years have strained their financial resources to the limit, or created actual deficits, by merely meeting current expenses and making absolutely unavoidable emergency improvements. Many badly needed improvements have been deferred by virtually every company on account of a lack of funds. It is necessary therefore, now that fares are beginning to be commensurate with costs, that the present increased rates be continued until lines are fully rehabilitated. Unless present fares are maintained, indefinite suspension of extensions and betterments will result and this would be almost fatal to many properties.

The report just completed shows that 548 cities in the United States, representing more than 90 per cent of the riding population in cities, are paying fares ranging from 5 cents with a 1 cent transfer charge to a flat rate of 10 cents.

The immediate result of the widespread inclination to adjust rates upward to the requirements of good service is found in the low number of electric railway receiverships for 1920. There were only 16, representing a total capital stock of $25,313,655, as compared with 48 receiverships, representing a capital stock of $221,259,354, in 1919. During the year 450 miles of track were dismantled and 308 miles of track abandoned.

An Electromechanical Device for Rapid Schedule Harmonic Analysis of Complex Waves★

BY FREDERICK S. DELLENBAUGH, Jr.

Secretary, Research Division, Electrical Engineering Department, Massachusetts Institute of Technology.

IMPROVEMENT in an art requires perfection of detail. Investigation of the details is often delayed, even though the procedure may be well understood, by the large amount of labor involved in handling cumbersome formulas or mathematical processes. The fundamentals of alternating-current theory are based upon a pure sine wave. More careful analysis considers waves formed of many multiple frequencies, which are found to exist in most practical applications. Thus not only the fundamental sine, but its higher harmonics, must be dealt with. The process of splitting up any known wave into its various components is well understood, but is slow and laborious if more than one or two harmonics are required. In present methods of analysis, it is at once striking how many combinations must be made to obtain the result. In mathematical methods this involves the calculation of a host of sums and products, elementary in form, but laborious in procedure. Methods of selected ordinates require many readings of ordinates from the curve, different sets being required for each harmonic. Graphical methods require a large amount of constructional detail. Machines involve changes of gears or pulleys, and many tracings of the curve.

The great ease with which electric circuits may be combined by multiple switches, and the accuracy with which electric measurements may be made, at once suggests the use of an electric network with some adjustable members to solve the curve under analysis (Bibl. 44). The device about to be described represents one way in which this may be done, and gives sufficient promise to indicate the possibility of great speed and reasonable accuracy with machines developed along these lines.

Theory

The electric analyzer is based upon the schedule method of analysis, so called because the mathematical processes may be combined in a schedule and save duplication of operations. The fundamental solution of Fourier's series, upon which it is based, may easily be derived as follows:

The series: $y = c_0 + \Sigma\, c_n \sin [n\,\theta + \psi_n]$ may be transformed to

$$y = c_0 + \Sigma\, [a_n \cos n\,\theta + b_n \sin n\,\theta]$$

When substitutions are made of:

$$c_n = \sqrt{a_n^2 + b_n^2} \qquad \text{and} \qquad \psi_n = \tan^{-1} [a_n/b_n]$$

In all of which expressions a, b and c represent coefficients of the different terms, n represents the order of the term, or harmonic, and is any integer, and θ represents the time function usually expressed by ωt. ψ is the phase angle of the harmonic, eliminated in the second expression by the introduction of both sine and cosine terms (Bibl. 4, 5, 6, 13 & 18).

If the area of the curve under analysis is the same on both sides of the zero line, then the term c_0 vanishes. If the curve is symmetrical with respect to its axis, then the even harmonics must be absent, and the values of n will be odd only. As these conditions are both true in most cases of alternating-current machinery, they will be the only ones herein considered.

By proper manipulation and integration, it is found that the coefficients sought are represented by the integrals:

$$a_k = 1/\pi \int y \cos k\,\theta\, d\,\theta$$

and

$$b_k = 1/\pi \int y \sin k\,\theta\, d\,\theta$$

where k is 1, 3, 5 etc.

In order to evaluate these integrals, an auxiliary curve may be obtained from the one under analysis by constructing curves of $y \sin k\,\theta\, d\,\theta$ and obtaining the area with a planimeter. This is the basis of many of the graphical methods. It also is possible to give a planimeter wheel such a motion that the vertical displacement is proportional to the values of y and the horizontal displacement is proportional to $\sin k\,\theta$ or $\cos k\,\theta$. In this case, the planimeter wheel will read the coefficient direct. This is the basis of most of the mechanical analyzers (Bibl. 65 & 82).

Both of these are indirect, however, and in order to obtain a direct mathematical method, further reduction of form must be obtained. It is shown in any text book upon the subject that the summation below represents the integral within certain limitations.

$$a_n/2 = 1/n\, \Sigma\, y_r \cos n/2\,\theta_r = 1/n\, \Sigma\, y_r \cos r\,\pi$$
$$a_k = 2/n\, \Sigma\, y_r \cos k\,\theta_r$$
$$b_k = 2/n\, \Sigma\, y_r \sin k\,\theta_r$$

All that is then necessary is to divide the curve into n equal parts, measure the $(n - 1)$ ordinates, multiply by the corresponding sine or cosine of the ordinate position, and add the results. The sum divided by

To be presented at the 9th Midwinter Convention of the A. I. E. E., February 16-18, 1921.

★ This Electric Analyzer was designed and manufactured in the Research Division Laboratories of the Electrical Dept., Mass. Inst. of Technology, where it has been in successful use for some time.

$n/2$ will give the coefficient sought. The results are accurate, provided that there are no harmonics present of an order higher than the value of n.

The number of ordinates $(n-1)$ must be at least equal to the order of the highest harmonic, and, for waves containing only odd harmonics, need only be taken over one-half the wave. Thus for analyzing for the 1st, 3rd and 5th harmonics, the curve must be divided into six parts giving five ordinates, and if there are no harmonics present greater than the 5th, the results will be accurate within the error of measurement of the ordinates and of calculation. The method is quite old, and if worked out through all its stages, is quite laborious. It is interesting that Kintner (Bibl. 7) published a set of tables to help the calculations, but did not seem to see the duplications of effort later pointed out by Carl Runge (Bibl. 6 & 16). It is evident that since a large number of sines and cosines are used as multipliers, and as these are taken for definite recurring angles and multiples of angles, there must be a recurring sequence of functions used as multipliers. Runge thus showed that the total number of multipliers necessary was equal to the sines of the angles of division of the curve between 0 and 90. The data thus developed were put into engineering form by S. P. Thompson (Bibl. 10) and became the now familiar harmonic analysis schedule. An eleven-ordinate schedule capable of giving the 1st, 3rd, 5th, 7th, 9th and 11th harmonic, both sine and cosine terms, is given in the Appendix, Table XI.

Probably one of the most serious errors likely to occur in this method arises from the fact that the cosine terms are obtained from the differences of what may be large numbers, and therefore the condition exists where the differences consist of numbers smaller than the accuracy of the original products, and so may themselves be entirely due to error. Steinmetz (Bibl. 14) has worked out a modification of the schedule method to eliminate this source of error, but while mathematically successful, it increases the labor very greatly and so is not generally used. Another difficulty in practical application arises from the fact that higher harmonics are neglected, and a schedule must be adopted which includes a sufficient number of ordinates, so that the higher harmonics may actually be negligible. With an unknown curve, this is more or less guess work, although the highest harmonic present may sometimes be fairly accurately estimated, or the type of curve may be sufficiently familiar for the general magnitude of results to be known. Thus with the magnetizing current of transformers, it is generally known that unless saturations are carried to very high values, the harmonics above the 11th are extremely small, while with alternator wave shapes, a tooth harmonic may be observed as a ripple whose order may easily be estimated. If no ripple is observed, it is probable that no harmonics higher than the 13th exist. The labor required to solve a curve by the schedule method rises rapidly as the ordinates or harmonics increase. The rate of increase of labor is at least proportional to the square of the order of the highest harmonic. Schedules as high as 35 ordinates are given in the California Railroad Commission Report (Bibl. 21). F. W. Gover (Bibl. 18) has also furnished some interesting data upon the error to be expected from neglecting higher harmonics which are present. His results seem to indicate that unless the neglected harmonics are very prominent, the error is chiefly confined to the highest of the harmonics determined by the schedule method, but an analysis of a series such as given by a rectangular wave where the harmonics theoretically extend to infinity, and which requires a relatively large number of terms to approximate the curve, will give an error in all the harmonics determined by the schedule method for eleven ordinates, the error increasing in magnitude as the harmonics determined increase in order. In general, if the Schedule method is used intelligently, and with a knowledge of its limitations, it affords a very satisfactory method of analysis.

The Electric Analyzer

The new electric analyzer here described is based directly upon the schedule method, and is in substance an electrical network arranged to give the same result as that obtained by the mathematical processes. If an e. m. f. proportional to the ordinate y_r is impressed upon a conductance proportional to the sine or cosine of the ordinate angle $k\,\theta$, then the resulting current is proportional to their product, and it will be seen that this corresponds to one of the terms of the summation it is necessary to evaluate. Thus:

Let: $e = K_1\,y$ and $R = 1/\sin k\,\theta_r$

Then $I = K_1\,y \sin k\,\theta_r$

If a number of such circuits are connected in parallel, then the total current flowing will be the sum of the currents in each circuit. Thus, if a five-ordinate schedule is used as a basis, it will be necessary to have five adjustable voltages representing each of the measured ordinates, and a succession of resistances representing the various values of sines or cosines of the various angle multiples. As the ordinates remain the same for each curve, and only the angle functions change, it is evidently possible to have one setting of the adjustable voltages hold for the whole of one analysis, and the required values of resistance may be thrown in by multiple switches. In the use of the simpler schedules, dial switches may be used, but for more complicated schedules, gang switches are necessary to eliminate circulating currents. It will be understood that the current used for obtaining the solution of the schedule is direct current and bears no relation to the alternating-current wave under analysis. The analyzer does not analyze an alternating-current wave directly, but an oscillogram must first be taken of it and then ordinates measured at the proper in-

tervals, exactly as would be done for the mathematical schedule method.

The elementary principle is shown in Fig. 1, where three slide wires are used to provide the variable voltage and the sliders are connected from the sliding contacts through proper resistances to a common bus, to which is connected the indicating ammeter. Slide wires are the simplest means of obtaining variable voltage, but

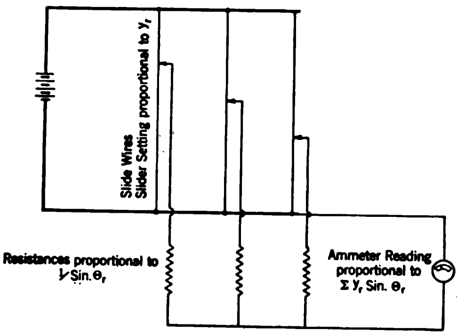

Fig. 1

of course are subject to the objection that if current is drawn off at the sliding contact, the voltage distribution is no longer linearly proportional. The error involved in the assumption that the voltage is proportional is given by the equation:

$$\text{Error} = \left(\frac{l - x}{x}\right) \frac{R\,x}{r\,l}$$

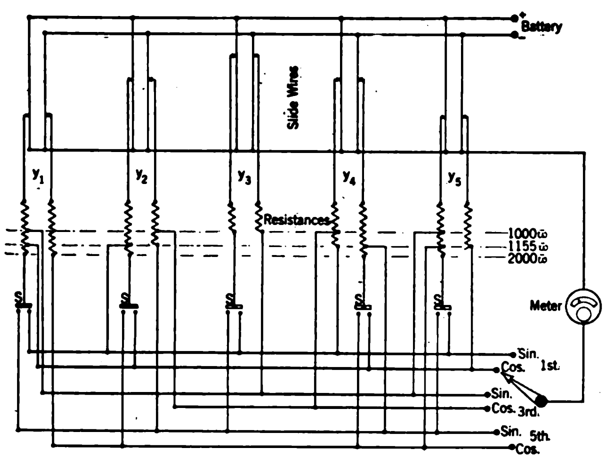

Fig. 2—Wiring Diagram for 5-Ordinate Analyser Giving 1st, 3rd, and 5th Harmonics

The dial-switch is turned to proper point and coefficient read on meter. The switches marked S, S, S, are mechanically coupled so that they move in unison and are thrown to the right for fundamental components and the left for 5th harmonic. Slide wires 2 ohms each.

where R is the resistance of the slide wire, r the resistance connected in series with sliding contact, x the position of contact and l the length of slide wire.

Thus it will be seen that if the series resistance is 500 times the slide wire resistance, the error is 0.1 per cent. As the accuracy of any harmonic analysis seldom exceeds 2 per cent, an error of 0.1 per cent is entirely negligible. Another point that brings in a difficulty is the fact that some of the angle functions are negative and some positive. Therefore, either the voltage or resistance must have two signs. Since negative resistance cannot be obtained for this purpose, it is easier to use a middle tap for the ammeter return circuit on each slide wire. As these middle taps will all be of the same polarity, there will be no current flowing and the position of the slider to the left or

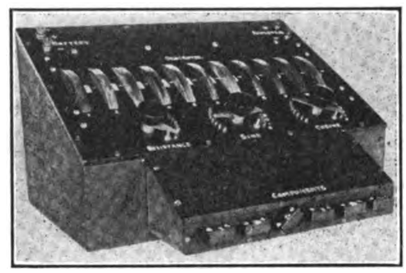

Fig. 3

right of the middle tap will give an e. m. f. of opposing signs. Fig. 2 shows the connections for a five-ordinate analyzer, the slide wires being folded back at the middle point and two sliders being used, so that they may both be attached to the same member of the device, and the same scale setting used for either positive or negative values, the change being made by switching in the resistance connected to the proper contact, leaving the other one idle. The values of resistance are calculated so that the maximum inherent error due to voltage distortion will be 0.1 per cent. The maximum will only occur in some of the ordinates and so the average error for the instrument will be less than this. The greater the number of slide wires, the less this average error will be. In order to calculate the values of the resistances, the lowest one is taken as 1000 ohms and the others designed to bear the same

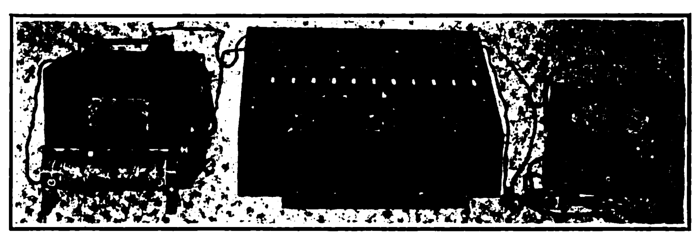

Fig. 4

proportion to this as the sine or cosine desired. Thus the smallest sine is 0.50. The largest is 1.00. Therefore, if the smallest resistance corresponding to the sine value of 1.0 is 1000 ohms, the largest resistance will be:

$$\frac{1.0}{0.5} \times 1000 = 2000 \text{ ohms}$$

The analyzer shown in Fig. 2 will analyze any wave not containing higher than the fifth harmonic and one where the wave does not cross the axis within

a half cycle, or, in other words, which has no negative ordinates, as no provision is made for ordinates of more than one sign. This may be taken care of very simply, however, by introducing a reversing switch in each slide wire, which is thrown over when a negative ordinate setting is required. The majority of curves met in ordinary practise do not require this additional refinement.

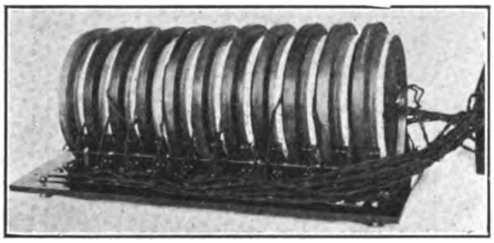

Fig. 5

Construction of Eleven-Ordinate Electric Analyzer

The eleven-ordinate analyzer based upon this scheme is shown complete in Fig. 3, and connected for operation in Fig. 4. The double slide wires, similar to those in the five-ordinate diagram, are wound upon maple plywood disks, six inches, (15.25 cm.) in diameter, with a projecting flange for manipulation. The edge of the disk carries a scale divided into 100 parts for the length of the slide wire, which is a little less than the periphery of 18.8 (47.8 cm.) inches. The three connections to each slide wire are made by flexible cables and carried to busbars along the under part of the face plate, as seen in the front part of Fig. 5, showing the slide wire disks assembled upon the face plate. Each disk projects through the face plate, and the scale reading against a setting line, painted on the face plate, is read through a one-inch slot beside the flange, as may be seen from Fig. 3. The sliding contacts are mounted upon a bakelite platform on the bottom of the face plate just behind the busbars, and consist of two phosphor-bronze springs per disk, bearing upon the two parts of the slide wire. The slide wires are made of No. 25 B. & S. resistance wire having 1.65 ohms resistance each, and, being connected in parallel, give the whole slide wire system a resistance of 0.15 ohms. The resistances representing the angle functions are placed along the inside of the containing box. The resistances are wound from high-resistance wire upon fiber spools 2½ inches (6.35 cm.) long, with ½-inch (1.27-cm.) cores and 1¼-inch (3.18-cm.) flanges. Each spool consists of two sections, the bottom section for connection to the negative contacts and the top section for connection to the positive contacts. For making the proper connections, six gang switches are mounted in a separate housing upon the front of the box, as shown in Fig. 3. These consist of a brass rod with five crossarms which fit between five sets of jaws upon each side. The jaws are all insulated from each other, so that closing the switch to either side, closes ten circuits and connects them to a common bus.

Each switch represents one harmonic, closed to the left for the sine component and to the right for the cosine component. In the position shown in Fig. 3, it is set for the fifth sine component. In this particular machine, two dial switches are also provided for further isolation of resistances. These are shown upon the front edge of the face plate in Fig. 3. These are entirely unnecessary for the operation of the machine and were added purely for experimental purposes to determine the errors resulting from circulating currents, with the point in view of further simplification. The third dial switch on the left is a resistance in the battery circuit for adjusting the slide wire current. The complete wiring diagram of this instrument is shown in Fig. 6, and the resistance data are given in the appendix.

Method of Operation

The current chosen for the slide wires depends upon the instruments available. In Fig. 4, the battery is connected through an auxiliary resistance for adjustment and about 0.20 ampere per slide wire was used in the tests given below. The meter for reading the harmonics was a Paul unipivot milliammeter, the scales of 20 and 2 milliamperes maximum being used. It does not make any appreciable difference what the resistance of the meter is, so a meter of this type is very convenient, as the sensitivity may be increased by multiples of ten by simply turning a switch; and thus

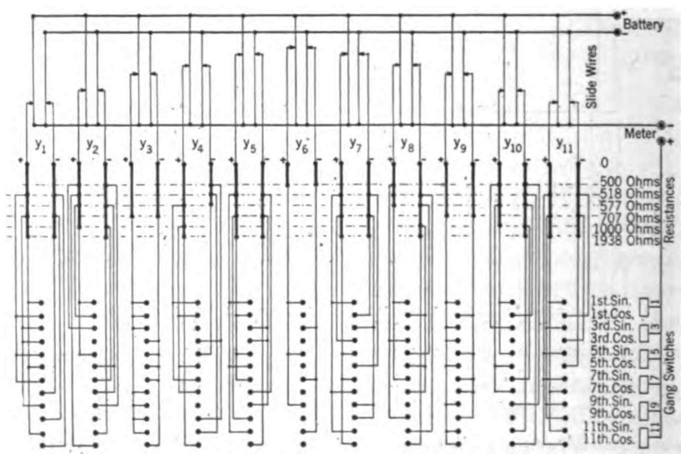

Fig. 6

the smaller harmonic components read with greater accuracy on the meter than is warranted by the method. If the current in the slide wires is increased five times, which is allowable, the meter required would be a 200-milliampere maximum reading instrument which is of commercial size. The slide wire current will still not be in excess of that easily furnished by a portable storage battery, so the auxiliary devices required are of easily obtainable nature.

To make the analysis, the instrument is first cali-

brated. This is done by setting the disks for a pure sine wave. Red marks are provided upon the scales, so that this can be rapidly done without reference tables. The first gang switch is then thrown to the left, or fundamental sine position, and the resistance in the battery circuit adjusted until the meter reads 100, or any other convenient amount. All other components should be zero. The switches are then turned successively through the other positions, and if the meter reads zero for all of them, it indicates that all connections are correct. This is a very rapid and invaluable check, for it can be made quickly any time and is an almost infallible indication of any open or short circuits, or poor contacts. All the resistances used in the sine fundamental position are used again in some other position, so that it includes them as well. Of course, it will not indicate poor connections, etc., that may develop for different ordinate settings but this has proved to be a very rare occurrence.

The eleven disks are next set to the values read from the curve, which should be done with some scale which will give the maximum ordinate a value of 80 to 100, or some decimal multiple of it, in order to insure the greatest range of slide wires, and thus obtain the maximum accuracy. If the battery current has remained the same, the readings obtained upon the meter will then give the values of the harmonic components directly, in terms of the fundamental sine wave used for calibration. Thus knowing the relative values of the scales used, the actual values of the coefficients may be easily determined. The readings are obtained by simply throwing one switch after the other, first to the left and then to the right, then returning it to the disconnected position and passing to the next switch. No change has to be made in the slide wire disk settings until another curve is analyzed.

Usually the relative magnitude of the harmonics is of more interest than the actual magnitude. This may be obtained directly from the instruments by adjusting the slide wire current, and this appears to be the only type of harmonic analyzer where this can be accomplished. After the disk settings have been made, instead of leaving the battery current the same as for the calibration and check, the fundamental switch is thrown to the sine position, and then the resistance in the battery circuit adjusted until the meter reads 100. Further manipulation of the switches then gives the harmonic coefficients directly in percentage of the fundamental sine. This machine also eliminates the chance of mathematical errors which creep in so easily with the multitude of operations necessary in the usual analysis by schedule.

Tests upon Electric Analyzer

The tables give a series of tests made to determine the accuracy of the network analyser. A very simple curve was first taken, as given in Table III. The only error will be seen to be the 11th sine coefficient. This is due to an error in the value of one of the resistances connected for this combination, and it will be noticed that this error is repeated in all readings. Increasingly trying combinations of terms were analyzed, and it will be seen that the maximum error occurs in Table IX, and amounts to 3.7 per cent. The value for comparison was obtained by working out the schedule method upon a calculating machine and thus obtaining the best possible accuracy by this method. It is interesting to note that in Tables IX and X for the triangular and rectangular waves, neither method gives accurate results, due to the harmonics above the 11th being neglected, and these types of curves having an infinite number of theoretical terms. Tables VII and VIII give the analyses of an ordinary transformer magnetizing current wave, and a peculiar wave made up of a sine with a superimposed discontinuous function obtained from the thermionic conduction in a three-electrode vacuum tube with alternating current impressed upon the plate circuit. These two curves are similar to the types met with in general practise, and show quite good accuracy, the maximum error being 3.32 per cent in the 11th harmonic and 1.88 per cent in the other harmonics. The last harmonic within range of the schedule will always give the largest chance for error as it means that only one point per cycle is determined, and this is just the requirement for determining the size of the component. Thus a small error in measurement of the ordinate or setting of the machine will introduce relatively large errors in the results.

From these tests and the underlying theory, the conclusion may be arrived at that for the usual type of curve an accuracy of 2 to 3 per cent may be expected from this type of instrument, which is sufficiently accurate for most practical requirements and compares

7th.	− 0.034	0	− 0.0346	0	− 0.0259	+ 0.8	0
9th.	+ 0.025	0	+ 0.0266	0	+ 0.0157	+ 0.9	0
11th.	− 0.018	− 0.001	− 0.0222	0	− 0.0105	+ 0.7	+ 0.1

NOTE. It will be noticed that the errors in the calculated values are of the same magnitude as those in the electric machine. The percentages given in the error column are calculated against the correct coefficients and therefore are chargeable in a large measure to the method rather than the electric device for interpreting it.

TABLE XI

SCHEDULE FOR THE ANALYSIS OF A PERIODIC CURVE IN WHICH ONLY ODD HARMONICS APPEAR UP TO THE ELEVENTH HARMONIC

Note. The two half-periods will be similar, so that if the mean line be taken between the highest and lowest points in the curve, there will be no constant term. For further simplification the origin should be taken where the curve crosses the zero line.

(1) Divide the half-period into 12 equal parts, and measure the 11 ordinates $y_1\ y_2\ y_3\ \ldots\ldots\ y_{11}$; y_0 and y_{12} being each zero.

(2) Then arrange these ordinates as under:

$$\begin{array}{llllll} y_1 & y_2 & y_3 & y_4 & y_5 & y_6 \\ y_{11} & y_{10} & y_9 & y_8 & y_7 & \\ \hline \end{array}$$

Adding.......................$s_1\ s_2\ s_3\ s_4\ s_5\ s_6$
Subtracting..................$d_1\ d_2\ d_3\ d_4\ d_5$

Note. s_1 stands for the sum of y_1 and y_{11}; d_1 for the difference between y_1 and y_{11}. Great care must be taken as to + and − signs throughout

(3) Group numbers, to obtain values for use with third and ninth harmonics, as follows:

$$\begin{aligned} s_1 + s_3 - s_5 &= r_1 \\ s_2 - s_6 &= r_2 \\ d_1 - d_2 - d_3 &= e_1 \end{aligned}$$

(4) Then select from the above numbers and put them in their places in the table below, *multiplying each by the sine set down in the left-hand column before it is entered.*

Angle	Sine-Terms			Cosine-Terms		
	Harmonics			Harmonics		
	1 & 11	3 & 9	5 & 7	1 & 11	3 & 9	5 & 7

Total first column	...	...	...	...	...	...
Total second column	...	...	...	...	...	...
Sum	6 B_1	6 B_3	6 B_5	6 A_1	6 A_3	6 A_5
Difference	6 B_{11}	6 B_9	6 B_7	6 A_{11}	6 A_9	6 A_7

Check:

$$A_1 + A_3 + A_5 + A_7 + A_9 + A_{11} = 0$$
$$B_1 - B_3 + B_5 - B_7 + B_9 - B_{11} = y_6$$

favorably with other methods of analysis. The error in the highest order of harmonic within range of the machine may be somewhat larger than this if the harmonic is prominent, but this is a characteristic of the method and not the particular instrument. The errors are all calculated against the value of the fundamental sine, as this is the fairest method. The importance of the harmonic is usually comparable with its relation to the fundamental, and any method of measurements from a curve cannot be expected to give great accuracy upon a harmonic which may have a magnitude of the same general order as the error of the method of obtaining the curve or the measurement of ordinates. When the great saving of time is considered, what might be called the overall effectiveness of the instrument is quite great.

Time Required for Harmonic Analysis by Different Methods

Harmonic analysis may be effected by three general methods:

1. Mathematical
2. Graphical
3. Instrumental

The time required by graphical methods renders them practically useless except for determining one or two harmonics. They have the advantage of picking out anyone harmonic within the accuracy of the construction, but do not seem to lend themselves readily to large groups of analyses.

The two best known instrumental methods are the Henrici-Coradi machine (Bibl. 55, 65) and the Westinghouse-Chubb polar analyser, (Bibl. 51 and 52). The former consists of five glass spheres, rolling within a carriage so that their displacement is proportional to the ordinates of the curve. The curve in cartesian form is plotted to fairly large scale and followed with a tracer point. Motion of the tracer point in the time-axis direction rotates cages around the glass spheres, the cages carrying planimeter wheels in contact with the spheres. Thus the radius of the circle upon which the planimeter wheel rolls is proportional to sin $k\theta$ and the motion of the spheres is proportional to y. The resulting displacement of the wheel is the solution of the Fourier integral given in the first part of the paper. Each cage carries two wheels at right angles. Thus for one tracing of the curve, the sine and cosine components of five harmonics may be determined. Resetting of the pulleys upon the top of the cages allows another five to be determined with another tracing of the curve.

The Westinghouse-Chubb analyser requires a curve in polar form, obtained from the polar oscillograph, from which a template must be made of cardboard. This is placed upon a platen, which is given a combined rotational and harmonic translational motion. An arm carrying a roller traverses the edge of the template and guides a polar planimeter in its extremity. After one complete trace of the template the reading of the planimeter gives one component of the harmonic for which the machine was set. Gears are then shifted for another harmonic and the process repeated. Unfortunately, the author has no records of time required for analysis by this machine. If high order harmonics are required, the time is rather long, but this is not fair to the machine, since it may easily be motor-driven and other work done while it is grinding out the analysis. Transferring curves from cartesian form to polar form requires a good deal of time and introduces a good deal of chance for error, so it is not satisfactory unless used with polar curves.

Some of the times required for analyses are as follows:

Method	Time	No. harmonics determined	Minutes per coeff.	Authority
Steinmetz........	10 hr.	10	60	D. C. Miller
Schedule.........	3 hr.	8	22.5	D. C. Miller
Schedule.........	1 hr.	8	7.5	F. W. Grover
Schedule.........	2.5 hr.	17	10.6	Author
Schedule.........	15 min.	3	5	D. C. Miller
Coradi Mch.......	13 min.	10	1.3	D. C. Miller
Coradi Mch.......	7 min.	5	1.4	D. C. Miller
Schedule..........	30 min.	6	5.0	Author
Electric Mch......	3.5 min.	6	.6	Author

The figures are not all comparable. They should be corrected for the number of harmonics determined, as the labor is not proportional with the different methods. The figures for the Coradi machine assume the curve already drawn. If the curve has to be enlarged from an oscillograph film, the added time for this should be included. The last two sets of data are based upon the time for doing the actual calculation, the readings from the curve having already been made, and being the same in each case, both times being for analysis of the same curve. The schedule analysis was performed upon a Marchant calculating machine. It can be done quicker with a slide rule, but the errors in the cosine components are then liable to be very great.

Concluding Comparison

In conclusion, it may be of interest to compare the advantages and disadvantages of the different methods.

SCHEDULE METHOD

ADVANTAGES	DISADVANTAGES
Simple	Very laborious and slow for more than a few coefficients.
Requires only a small chart for direction.	Not accurate where harmonics exist outside range of schedule.
Fairly accurate within theoretical limitations.	Subject to error unless calculating machine used, particularly in cosine components.
Reasonably fast for a small number of coefficients.	

WESTINGHOUSE-CHUBB

Accurate	Requires cardboard template of polar form.
Easy to operate	Difficult to use with curves in Cartesian form.
May be motor-driven and so require little labor.	Requires separate trace for each component.
Semi-portable	Moderately expensive.
Not difficult to obtain	Construction requires much machine work.
Easy to maintain	

HENRICI-CORADI

Accurate	Requires large curve.
Easy to operate	Special table, tracks, etc., must be provided.
Quick	Can only be manufactured by expert instrument makers.
Five harmonics completely determined with one trace.	Expensive.
	Difficult to obtain
	Requires care for maintenance.
	Not portable.

ELECTRIC

Easy and simple to operate.	Subject to limitations inherent with schedule method.
Moderately accurate and eliminates many chances for error.	Subject to usual difficulties of electric networks.
Very quick, as only one group of readings required from curve.	Not extremely accurate.
Reads coefficients either in actual values or per cent of fundamental sine component.	Number of resistances increases rapidly with order of harmonics.

Easy to construct, requiring common materials and little expert workmanship.	Requires storage battery and meter in addition to analyzer itself.
Inexpensive	
Easy to maintain	
Auxiliary apparatus of common form.

MOVING PLATFORMS FOR CROSSTOWN LINES

A moving platform to handle crosstown traffic in 14th, 42d and 57th streets, New York, was briefly described in a paper read by Mr. L. B. Stillwell last November at a meeting of the New York section of the American Society of Civil Engineers. Some further interesting details in regard to the proposed construction and method of electric drive have recently been published in the *Electric Railway Journal.*

The proposed electric carrier system of propulsion will permit the use of platforms mounted on car trucks, which will effect a material reduction in the cost of construction, operation and maintenance, and also of the space required. The distinguishing characteristic of this system is the method of propulsion. Instead of a complete motor being mounted upon the car and transmitting mechanical power therefrom through gears to the wheel, or driving carrier wheels on which the platform moves, the three-phase induction motor of the squirrel-cage type is used. These parts are separated, that corresponding to the stationary or primary element of the motor being straightened out into sections about 5 ft. long and placed midway between the rails in the roadbed, while that corresponding to the revolving element, also straightened out, forms a continuous short-circuited secondary mounted on the bottom of the car. The primary elements, when energized with three-phase current by induction, magnetize the short-circuited secondary which extends continuously along the bottom of the car. The result is that the force created between the induced secondary current and the shifting field of the primary propels the car.

The scheme proposed is to use three platforms of 27 in., 27 in. and 57 in. width, respectively, moving at 3, 6 and 9 mi. per hr. The high-speed platform carries seats for two persons spaced at 3-ft. intervals. It is proposed to use identical construction for the electrical elements on the three platforms, the different speeds being secured by operating the intermediate platform at double the frequency of the low-speed platform, and the high-speed platform at three times the frequency of the low-speed platform. All conductors and windings carrying power will be imbedded in the roadbed and thoroughly protected and insulated against damage by water in a manner to make accidental contact and danger very remote. The current will be carried at relatively high potential to transformers located at points along the system and thence by cables in ducts to the primary element between the rails. The primary element, as explained, is not continuous, but will be installed at intervals in sections about 5 ft. long.

The power supply will be produced by a motor generator set, in which a single motor will drive three generators mounted on a single shaft. The generators will produce three-phase alternating current at 10, 20 and 30 cycles respectively or some multiple of these frequencies. As the speed of the different platforms depends on the frequency of the three-phase current applied to the primary, it is clear that any platform may be operated at a lower speed by changing the frequency supplied to it, in case it should be desired to shut down one platform and operate the other two, or in case one platform only is to be operated.

The application of this system to the Forty-second Street loop would require three platforms, each approximately 10,100 ft. long. The seating capacity of the 9-mile platform would be 31,680 passengers per hour in each direction. The weight per seat for all three elements would be roughly 375 lb., while that of a loaded subway train is approximately 1,800 lb. per passenger.

Permissible Operating Temperatures of Impregnated Paper Insulation in which the Dielectric Stress is Low

BY L. L. ELDEN

Edison Electric Illuminating Co. of Boston.

PRESENT day practise in the operation of low-tension cables (7500 volts or less) is mainly based upon the temperature limitations generally specified by cable manufacturers and others, who from extensive experiments and research have determined the temperature at which the physical structure of impregnated paper as used for cable insulation, suffers marked deterioration in both its mechanical and electrical properties.

Naturally the conditions thus observed have formed the basis for certain guarantees on cable, a course which has had the support and approval of large users of cables as the result of their observations and experience. As the result of this experience there was evolved the present Standards rule limiting the permissible conductor temperature in low-tension paper insulated cable to 85 deg. cent., with suitable reductions in temperature as the voltage is increased. There being no evidence before us that paper insulation has suffered injury at a temperature as high as 85 deg. cent., and as this limit is slightly lower than the temperature at which paper has been noted to suffer deterioration (93.5 deg. cent.) we may, therefore, assume that low-tension cables may be safely operated up to 85 deg. cent. for indefinite periods without injury.

We find an apparent conflict with this temperature limitation in another Standards rule covering fibrous or Class A insulation when used for the insulation of electrical apparatus. This rule in specifying 90 deg. cent. as the permissible observable temperature for impregnated materials also permits an allowance of 15 deg. cent. for hot-spot correction or temperature gradient through the insulation, this raising the limit of conductor temperature to 105 deg. cent., or 20 deg. cent. higher than is specified for paper insulation in cables. For non-impregnated materials it is to be noted that this rule provides for a reduction of 10 deg. cent. in the above values.

It is questionable if the limit placed upon Class A insulation is not too high, since in the writer's experience it is possible to point out cases where Class A insulation has failed in modern apparatus, transformers and rotating machines, in which the temperature of the conductors has never been permitted to reach the observable limit of 90 deg. cent.

While the initial failure in these cases has been limited to a relatively small portion of the winding, the insulation on the balance of the winding has been found dried out to such a degree as to be too brittle to withstand the handling necessary to make replacements and an entire rewinding has been required.

There is a marked difference in the conditions under which insulation in electrical apparatus and in cables is operated. In electrical apparatus in general, excluding oil-cooled equipment, the insulation is largely exposed to the air at all times, and in many instances is cooled by forced ventilation, thus affording ideal conditions for the impregnating compounds between layers to be gradually dried out or expelled, leaving the entire body of the insulation to become more brittle as it is continued in service.

In the case of cable insulation wrapped in a waterproof covering or enclosed in a lead sheath, it may be contended that since evaporation is impossible, the insulating compounds will be retained in their original sticky or semi-fluid condition, and the insulation as a whole retain its original value if not otherwise injured.

This, however, is not always borne out in practise, as was noted recently when attempting to install some 1,500,000-cir. mil, 600-volt, single-conductor cable which had been held on the original reel as emergency stock for over ten years. The insulation on this cable, although never in service, was found to be too brittle to withstand installation.

Unfortunately, cables are not always laid in horizontal positions, thus affording opportunities for the compound to gravitate to the lower positions in the cable, leaving sections of cable at the higher levels free of compound and unsuited to heavy or maximum loading conditions. These conditions develop more rapidly in cables alternately heated and cooled, with resulting expansion of the sheath creating voids, thus permitting migration of the compound.

While these conditions are beyond the control of the user, he also must contend with the imperfections in manufacturing processes whereby the impregnation is sometimes imperfect, thus leaving dry sections of insulation which hazard the safety of cables so constructed when operated at the higher temperature limits.

Operating practise in the loading of low-tension paper-insulated cables as reported by various users varies so widely that it is impossible to draw exact conclusions or to establish any fixed rule as to the maximum temperature at which such cables may be safely operated.

Reports are presented from time to time showing that cables of sizes specified have successfully carried certain loads in amperes for stated periods either

To be presented at the 9th Midwinter Convention of the A. I. E. E., February 16-18, 1921.

regularly or as occasion required, without apparent damage to the cables. The loadings thus specified have indicated that the commonly accepted ratings of such cables have been materially exceeded, even though the final effect on the cable could not be determined. Reports of such a character are valueless unless accompanied by the necessary supporting data clearly showing the conditions under which the record was made.

In the last analysis the sheath temperature is the only definite factor from which to determine the actual operating temperature of a cable, since the temperature of the conductor may be determined with a fair degree of accuracy from the sheath temperature.

It has been frequently suggested that the insulation normally used on heavy low-tension cables, 250 to 600 volts, while necessary for mechanical strength, is really unnecessary for the voltage employed, and that therefore a substantial amount of deterioration may occur without affecting the life of the cable.

If this view be accepted for low-tension cables, it cannot be accepted with the same degree of confidence for cables operating at 2300 - 4000 - 7500 volts, since in no case is the factor of safety, if based upon the thickness of insulation employed on the higher-voltage cables, in any manner comparable with that of low-tension cables.

To secure the same degree of safety the thickness of insulation must be increased many times, to do which is at once uneconomical and at times, a physical impossibility. That the same factor of safety is not attained in practise is amply demonstrated by the record of failures in cables from 2300 to 7500 volts, they being sufficiently numerous as to form a most powerful argument against any proposal to increase their loading by an increase in operating temperature.

For a number of years it has been customary to provide for very severe bending tests in all specifications under which the breakage of the paper insulation must be kept at a minimum. If as has been reported by a number of eminent investigators and cable manufacturers, paper when subjected to a temperature only slightly higher than 85 deg. cent (*viz.* 93.5 deg. cent) does actually become brittle and lose a substantial percentage of its original tensile strength, then it must of necessity be unable to withstand the bending tests specified for new cable.

Since it is not always possible to be sure that cable once laid, will never be disturbed or moved to new positions, it must follow that the users, when reinstalling cable which has been operated at temperatures sufficient to damage in some measure the insulation next to the conductors, must finally accept the cable in its new position under a materially reduced standard of perfection from that which was acceptable at the time of original installation.

If this is a fair statement, then it must be admitted that the original specification was too severe and that it is not unlikely that cables which may have been rejected under tests were at least as serviceable as cable reinstalled under the conditions suggested above.

To retain the present provisions for bending tests may therefore be regarded as an economic waste as reflected in the final cost of cable. It cannot be denied that if paper is subjected to high temperatures its useful life as insulation must gradually or rapidly be shortened as the case may be.

The real question for the cable user to decide is the rate of depreciation which he is willing to accept as the result of operating his cables at high temperatures. Various interests have contended for different rates of depreciation on underground plant, but it is contended by the writer that in specifying a rate to be applied to paper-insulated cable there should not be included any allowance for depreciation due to loading. Depreciation allowed for aside from any consideration of values at different periods should only include allowances for physical depreciation due to wear and tear in position, external injuries, electrolysis and similar agencies affecting the life of the cable sheath.

This point of view has been rigidly adhered to in the operations of the company with which the writer is connected in that loading of cables has been such that, so far as is known, the temperature limitation of 85 deg. cent. has not been exceeded. In the operation of its 230-volt d-c. system during the past eleven years, careful records of d-c. feeder loads have been maintained, from which the data in the following tabulation were obtained.

This record includes only those feeders which are composed either in whole or in part of one million single-conductor or one million concentric cables, and shows the number of hourly readings in excess of 800 amperes which have been observed each year. It is of interest to note that while a total of 75,800 readings have been noted in the eleven-year period, 53,040 or 70 per cent have occurred in the winter months, clearly indicating the seasonal load characteristics of the system which afford such favorable conditions for operating cables at relatively high load values during the period of lowest temperature.

In estimating probable temperatures from this record for comparison with the test records presented by Mr. Torchio allowance must be made for the lower sheath temperatures noted in this system, these resulting from uniformly lower earth temperatures and in some measure to the use of smaller conduit lines, none of which are sufficiently congested to create abnormal temperatures.

The relative values may be determined from a number of typical test readings here presented. Temperature readings were taken just inside ends of ducts in manholes and are comparable with readings taken from thermocouple No. 20 in Mr. Torchio's exhibit:

Observations on June 6, 1920 were taken after four days of very hot weather.

Viewing these data in the light of our operating experience and allowing the usual temperature gradient through the insulation, it is questionable if the conductors of any of the cables under observation have ever reached a temperature of 85 deg. cent. unless due to local hot spots of which there has been no evidence.

Summarizing our experience with this installation, it appears that in eighteen years of use of single-conductor and concentric low-tension feeder cables there is no record of a failure of these cables due to loading conditions. This may be declared to be evidence of too great conservatism in the use of the plant investment in question. We believe, however, that it is justified by freedom from interruptions of service in a city where rendering the best possible service at all times is considered the first duty of the company.

With this record behind us, we are loath to depart from our present practise and approve a higher degree of loading which must invariably develop new troubles, until conclusive evidence is at hand which will justify increasing the present limit of 85 deg. cent. for low-tension cables as now incorporated in the Standards.

Viewing the data presented by Mr. Torchio in the

most liberal light, I cannot agree that it is conclusive since the physical condition of some of the sections of cable submitted after completion of his tests leaves much to be desired if the cable in question was to be continued in service. Further, the exhibit in question clearly shows the risk involved in basing the loading of cable upon temperature observations at one point. It is almost a foregone conclusion that as shown in this case there are points in any cable, where, due either to local conditions of external temperatures or to the effect of dry spots in cable insulation, excessive heating develops with resulting rapid deterioration and final destruction of the insulation. To operate low-tension cables at higher temperatures than at present is permissible cannot be all gain, since the carrying capacity of other cables within the same conduit must be reduced owing to the higher duct temperatures which must prevail. That such conditions are not unlikely to develop new troubles cannot be denied, therefore in the interest of safety to plant and avoidance of cable failures in general it seems the better policy to adhere to conservative temperature ratings rather than to operate at the highest possible temperature.

If, as seems quite likely, the existing temperature limit of 85 deg. cent. may be safely exceeded for short periods without injury to paper insulation, it would seem preferable to apply an overload rating to low-tension cables which may be taken advantage of as occasion requires rather than to operate such cables on a load factor basis.

The objection to the latter method lies in its impracticability of application to the operation of any system of distribution. In actual service each feeder operates on a load factor of its own which may or may not coincide with the system load factor, or whose maximum load period may be independent of the system peak load, hence each feeder must be treated as an individual case. Further, load factor makes no distinction between seasonal loadings, a most important factor in the operation of a cable system, since loadings which may be permissible in winter must be materially modified during summer periods. Finally while it may be possible to specify an allowable overload rating for this class of cables in terms of temperature, it is next to impossible to determine whether such limit is not exceeded in practise, a condition which should cause one to lean to a conservative standard such as the present Standards rule as the more desirable policy.

HUGE CABLE PROJECT IN SWEDEN

Twenty-four car loads of underground cable apparatus now on its way to Stockholm, Sweden, is part of a gigantic underground cable system which the Swedish Government intends to install between Stockholm and Goteborg. It w ll be 320 m les long. When t is completed, it will be the greatest underground cable line in Europe, and second in the world only to the 450 mile line now operating between Boston and Washington. It will be capable of carrying two hundred conversations simultaneously from Stockholm to its other terminus.

To complete the big Swedish project, it will be necessary to manufacture a total of 425,000,000 conductor feet of cable, 25,000 loading coils and 8 repeater stations with 300 repeaters.

Mr. A. H. Griswold, Assistant Chief Engineer of the International Western Electric Company who has just returned from Sweden where he has been making arrangements for the installation of the big cable line states that it will require about a year and a half to put the system into operat ng condition. The work will require about a thousand workmen in addition to a large staff of engineers.

An idea of the magnitude of the new Swedish line of communication can be gleaned from the fact that 6,500,000 pounds of lead and 3,350,000 of copper are being used in its manufacture.

INDUCTANCE COILS IN RADIO COMMUNICATION

The inductance coil is one of the fundamental elements in all radio circuits and improvements in the efficiency of radio systems depend very largely on the design and nature of these coils. There has been hitherto no comprehensive information available on the constants and behavior of such inductance coils. A careful research along these lines has been in progress at the Bureau of Standards having in view the use of coils both in practical radio operating circuits and as standards. The inductance, resistance, and capacity of typical coils have been measured and studies have been made of the theory governing their resistance and capacity. These quantities change with the frequency, and pre-determination of their value is of considerable importance in radio design. The results of this work have given formulas for calculating the capacities of short single-layer solenoids, pancake coils, and multi-layer coils of circular or square section and large diameter. Special design shielded coils of calculable capacity have been developed for use as standards.

Hysteresis Effects With Varying Superposed Magnetizing Forces

BY W. FONDILLER and W. H. MARTIN

Western Electric Co. Inc. American Telephone & Telegraph Co.

THE hysteresis effects discussed in this paper occur when magnetic fields are produced in iron by electrical circuits carrying simultaneously currents of different frequencies. Investigations have shown that when two currents of different frequencies are so superposed, the losses in the iron corresponding to each frequency may differ greatly from those obtained when each frequency is acting alone in the circuit. These effects are, therefore, particularly important in the electrical communication field because of the practise of transmitting over one circuit currents of different frequencies. Predictions of the behavior of iron-cored inductance coils and transformers in such a circuit may be erroneous if based on measurements of the iron losses which have been made in the usual way with single-frequency test currents.

These effects first became of importance in the plant of the Bell Telephone System as a result of the long established practise of arranging practically all the long telephone toll lines for simultaneous operation of telephone and telegraph circuits over the same wires. This system of "compositing" the lines has been generally arranged to provide one grounded telegraph circuit over each of the two conductors used for the telephone circuit. Each of these telegraph circuits can be operated either "full duplex" or "half duplex". In full-duplex operation a telegraph circuit is used to send messages simultaneously in both directions. In half-duplex operation the circuit is operated in only one direction at a time but may be used in either direction. Thus as many as four independent trains of direct-current telegraphic signals may be passing over the two conductors provided for the telephone circuit.

The compositing of a line is accomplished by the use of networks which transmit currents of frequencies in one range and discriminate against currents of frequencies in another range. A standard form of "composite set" is shown in Fig. 1. In the two wires of the line is inserted the network *a b c d*, consisting of inductances L_1 and capacitances C_1 and C_2, which transmits efficiently between the line and the telephone terminals, currents of frequencies in the range above 100 cycles. Connected to each of the line conductors are shown selective networks *a e* and *d f* each consisting of L_2 and C_1, which discriminate against this range of frequencies, but transmit efficiently the lower frequencies, including direct current, used for the operation of the telegraph circuit. Each of the line conductors thus provides a grounded telegraph circuit. To each telegraph terminal of the circuit is connected a duplex telegraph set which, by means of the usual balanced bridge arrangement, permits two-way operation.

With the application of this compositing system to loaded telephone lines[1] in which the inductance of the circuit is increased by the insertion at uniform intervals of toroidal iron-core inductance coils, it was observed that the operation of telegraph over long loaded circuits materially impaired the transmission of the telephonic currents. The effect was manifested by an irregular breaking up of the speech sounds which seriously interfered with the intelligibility of the telephone conversation, and in addition, the average volume of the received speech sounds was materially reduced. When a sound was sustained over the telephone system during operation of the telegraph circuits, a rapid undulation or fluttering of the tone was observed. This effect has become known as "flutter" and will be so designated here.

LINE TESTS

To obtain a quantitative measure of this flutter, tests were made to determine the effects which the telegraph currents had on the transmission of single-frequency currents in the telephone range. In what follows currents of frequencies in the range from 200 to 2000 cycles will be referred to as "telephone" or "audio-frequency" currents. Currents corresponding to the usual d-c. telegraph signals or single-frequency currents in the range from 0 to 100 cycles will be called "telegraph" or "low-frequency" currents.

For these tests, a circuit such as shown in Fig. 1 was employed. This circuit consists of a loaded telephone line at each terminal of which is connected the standard compositing arrangement for providing one duplex telegraph circuit over each conductor. The telephone apparatus at one end of the cable is replaced by an oscillator capable of sending into the line, cur-

To be presented at the 9th Midwinter Convention of the A. I. E. E., February 16-18, 1921.

into the line to record the telegraph currents over each conductor. The record of the telegraph current obtained is a combination of both the telegraph and the telephone current, but the magnitude of the latter is small compared to the former. With this circuit, data regarding the flutter are obtained by making oscillograph records of the single-frequency telephone cur-

V_2—800-cycle telephone current.

of an early type developed for cable circuits. They were made up on toroidal cores consisting of a number of turns of fine iron wire. These cores have an effective

initial permeability of approximately 60. For a current of 800 cycles the ratio of received to sent currents over this circuit is about 0.31. The circuit has an attenuation per mile at this frequency of 0.013 and corresponds in its total attenuation effect to a length of 10.7 miles of standard No. 19 A. W. G. cable (88 ohms resistance and 0.054 microfarad capacitance per loop mile).

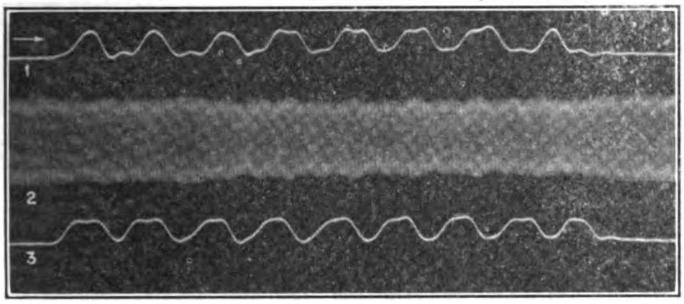

Fig. 7—Flutter Effect with Cable Circuit Loaded with Inductance Coils Having 30-Permeability Cores

V_1—Telegraph current, half duplex, 17 dots per second.
V_2—800-cycle telephone current
V_3—Telegraph current, half duplex, 18 dots per second.

Fig. 2 is an oscillogram showing the flutter obtained over a circuit in this cable with an 800-cycle telephone current of 0.002 ampere sent out on the line. The telegraph was operated in one direction over only one wire, that is, half duplex on one wire. The telegraph current is that corresponding to a succession of "dots" sent at a rate of 17 per second, and the maximum current reached is 0.055 ampere. The oscillogram was started with the telegraph not operating, and then by means of a commutator on the oscillograph the telegraph signals were placed on the line and removed near the end of the record.

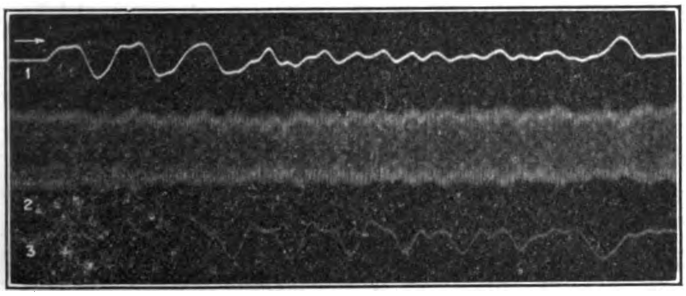

Fig. 8—Flutter Effect with Cable Circuit Loaded with Inductance Coils Having 30-Permeability Cores

V_1—Telegraph current, full duplex.
V_2—800-cycle telephone current.
V_3—Telegraph current, full duplex.

It will be noted that the 800-cycle wave is constant in amplitude at the start, but that during telegraph operation, the amplitude is at times materially reduced. Fig. 3 is a record of the same conditions as Fig. 2 with the exception that the frequency of the telegraph "dots" has been reduced to nine per second. From these records it is seen that a marked diminution of the 800-cycle wave is obtained at intervals corresponding to changes in the magnitude of the telegraph current, that is, when the telegraph current is increasing at the beginning of a telegraph signal or decreasing at the end of a signal. The time lag indicated on the oscillogram between a change in the telegraph current and the corresponding diminution in the telephone current is due to the fact that the telegraph record is taken at the sending end of the cable and the telephone at the receiving end. An appreciable time is required to propagate a wave over the loaded circuit.

Fig. 4 shows for the same circuit the effect of half-duplex telegraph operation on each wire of the telephone circuit, that is, one set of telegraph signals passing over each wire. The signals on the two wires are sent at slightly different speeds, (17 dots per second on the first wire, oscillograph vibrator V_1, and 18 dots per second on the second wire, vibrator V_3) and the flutter effect is rather irregular. The combined effect of the two sets of telegraph pulses is greater than that obtained on the oscillogram of Fig. 2.

Fig. 5 shows the effect with full-duplex telegraph operation over each wire, that is, when four sets of telegraph signals are simultaneously passing over the wires. In this case, also, each set of signals is a succession of dots. The records of the telegraph currents show for each wire the combination of the signal currents which are flowing in the two directions.

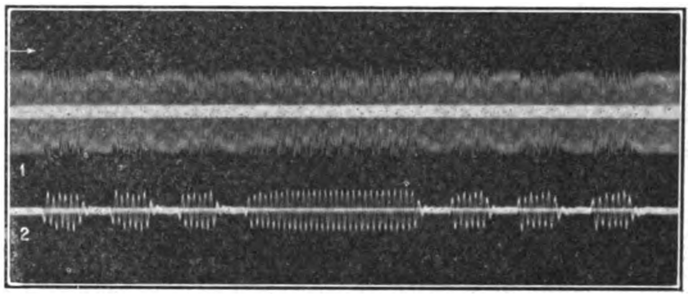

Fig. 9—Flutter Effect of 800-Cycle and 200-Cycle Currents Superposed on Loaded Cable Circuits

V_1—800-cycle current.
V_2—200-cycle current.

Figs. 6, 7 and 8 are oscillograms taken over a No. 13 A. W. G. cable circuit of the same length as that used for the above oscillograms but loaded with inductance coils of more recent design. These loading coils are made up on cores which have an effective initial permeability of about 30. The flutter effect with these coils is much smaller than that with the 60-permeability core coils.

Fig. 9 shows an oscillogram in which the telegraph current has been replaced by pulses of 200-cycle current. While the 200-cycle current is superposed there is on the average a diminution of the 800-cycle current received over the circuit. This oscillogram was taken over a different circuit from those described above and therefore the results are not directly comparable.

Two ratios may be used to express numerically the effects shown on these oscillograms. One is the ratio of the average amplitude of the high-frequency wave obtained during telegraph operation to the amplitude with the telegraph not working. The second is the ratio of the minimum amplitude obtained during telegraph operation to the amplitude of the undisturbed portion of the wave. The first ratio may be taken as a measure of the reduction in the volume of the transmitted speech sounds and the second as a measure of the distortion to which these sounds are subjected by the flutter.

Table 1 below gives these ratios for the oscillograms of Figs. 2, 4, 5, 6, 7 and 8, showing for both cable circuits the three conditions of tele raph operation namely, (1) half-duplex operation on one wire, (2) half-duplex operation on two wires, and (3) full-duplex operation on two wires.

TABLE I

Ratio of Amplitudes of Received 800-Cycle Current With and Without Telegraph Operation

Telegraph operation	60-Permeability coils		30-Permeability coils	
	Average amplitude	Minimum amplitude	Average amplitude	Minimum amplitude
1. Half-Duplex operation on one wire.........	0.63	0.34	0.92	0.81
2. Half-Duplex operation on two wires.........	0.53	0.11	0.90	0.78
3. Full-Duplex operation on two wires.........	0.42	0.08	0.88	0.75

Sim lar investigations of longer circuits have shown that the flutter effect increases with the length of the circuit. Its magnitude depends upon the type of loading coil, being less for coils having the lower permeability cores and a so for those with lower flux density in the core. Tests on loaded open wire lines showed results similar to, although materially smaller than, those obtained in cables. The loading coils in open wire lines are spaced about seven times as far apart as in cable and are made up on large cores.

It was observed, in addition, that the amount of flutter was affected by the following factors: The frequency and amplitude of the telephone current, the speed at which the telegraph signals are sent, and the amplitude and wave shape of the telegraph signals. By studying these factors, it was found that the diminution of the received telephone current increases as the frequency of the telephone current is increased, and for any frequency decreases as the amplitude is increased. When the speed of sending the telegraph signals is increased, or when the magnitude of the telegraph currents is increased, or when the rate of change of the telegraph current at the beginning and end of a signal is increased, the flutter in the telephone current becomes greater.

Since the flutter occurred only in loaded circuits, it was naturally assumed to be due to changes in the "constants" of the loading coils and therefore to changes in the total inductance or effective resistance of the circuits. The effects are transient changes in the magnitude of the received current or, since the current sent into the line is constant, there is a decrease in the ratio of the received to the sent current. Calling the received current I_2 and the sent current I_1, the relation between this ratio and the attenuation a per unit length of the circuit is given by the formula

$$\frac{I_2}{I_1} = e^{-la} \tag{1}$$

where e is the base of the natural logarithms and l is the length of the circuit. For telephone frequencies well below the critical frequency (that is, the frequency beyond which the coil loaded line has practically infinite attenuation) the attenuation constant is given by the relation

$$a = \sqrt{1/2\,\sqrt{(R^2 + p^2L^2)\,(G^2 + p^2C^2)} + 1/2\,(RG - p^2LC)} \tag{2}$$

in which R, L, C and G are respectively the total effective resistance, inductance, capacitance and conductance per unit length of the circuit and p is 2π times the frequency f. For the case of the loaded line, where $p\,L$ is large compared to R, a close approximation of equation (2) is

$$a = \frac{R}{2\sqrt{L/C}} + G/2\,\sqrt{L/C} \tag{3}$$

For the circuit having the 60-permeability core loading coils the first term on the right-hand side of this equation is about eight times as large as the second term and the former is therefore controlling. Neglecting this last term in equation (3), the change in attenuation may be caused by an increase in the resistance or a decrease in the inductance. Referring to the average reduction in the received current given in Table 1 for the oscillogram of Fig. 2, there would be required an average increase in the resistance per loading coil of 200 per cent, or reduction in the inductance per loading coil of about 60 per cent, to account for the attenuation obtained.

The characteristic impedance of a coil loaded telephone circuit for the frequencies for which the above attenuation formula applies is given by the relation:

$$Z_0 = \sqrt{\frac{R + j\,p\,L}{G + j\,p\,C}} \tag{4}$$

Since for telephone frequenc es $p\,L$ and $p\,C$ are large compared to R and G respectively, the relation may be reduced to the approximation

$$Z_0 = \sqrt{L/C} \tag{5}$$

Equation (5) shows that the impedance is affected by a change in the inductance of the loading coils, but, for the relative magnitudes of R and $p\,L$ stated above, is insensitive to changes in resistance. Measurements of the impedance of the loaded circuits for frequencies in the telephone range had shown only a

small change in the impedance when the telegraph was operated. On this basis then it is apparent that the flutter effect is not primarily the result of a change in inductance of the loading coils, but is due to a change in their effective resistance

Laboratory Tests

In the investigation to determine the explanation of this change in the resistance of the loading coils, consideration was given to data which had been accumulated on the various types of coils showing the effect of superposing direct current. The communication engineer is primarily interested in the inductance and effective resistance of a loading coil to alternating current within the range of telephone frequencies. A characteristic curve showing how the constants of a 60-permeability core coil are affected by superposed direct current is given in Fig. 10. The ordinates are

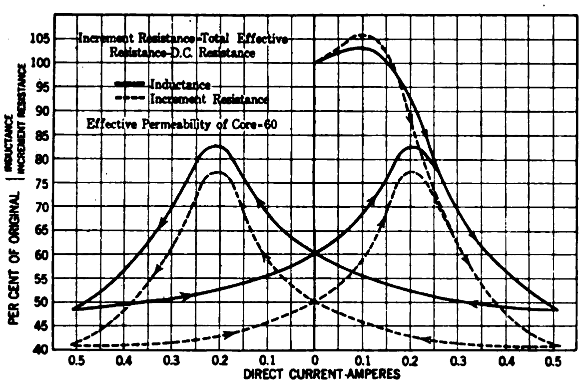

Fig. 10—Variation of Loading Coil Inductance and Effective Resistance with Cycles of Direct-Current Magnetization

percentages of the original inductance and effective resistance respectively, and the abscissas are strengths of superposed direct current in terms of current I or magnetic field H. The relationship was obtained by using a special bridge circuit which enabled superposing direct current on the alternating current. In this bridge the loading-coil core was subjected simultaneously to the action of a telephone frequency current and of a desired value of direct current.

The inductance and effective resistance of the loading coil were measured with a 1000-cycle current of 0.001 ampere. The values of L and R when there was no superposed direct current are taken as the original magnitudes from which the percentage change is calculated. In the curve of Fig. 10 the resistance which is plotted is not the effective resistance, but is the increment in resistance due to alternating current losses *i. e.*, the measured effective resistance less the direct-current resistance of the coil. From Fig. 10 it is seen that there is only a slight change in the inductance and effective resistance to the telephone current for a constant current strength not exceeding 0.1 ampere. For larger values of superposed direct current there is a marked decrease in both of these quantities.

The analysis of the attenuation and impedance relations of a coil loaded line which was given above indicated that the increased attenuation which accompanied the telegraph current could be accounted for only by substantial changes in the effective resistance or inductance of the loading coil. However,

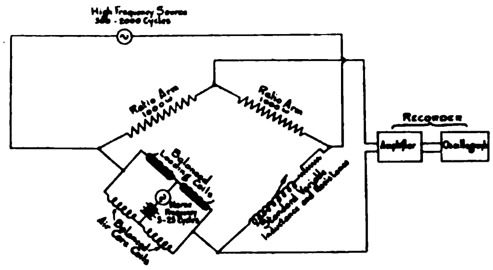

Fig. 11—Simplified Diagram of Special Bridge for Determining Flutter Effects

it has been standard practise in the plant of the Bell system, in order to guard against permanent magnetization of the coil cores, to limit the telegraph current to a maximum of 0.1 ampere. We need, therefore, consider only the part of the curve in the region from zero to 0.1 ampere direct current. For the oscillograms referred to above only that part between 0 and 0.055 ampere is pertinent, since the latter is the maximum value of telegraph current used. It is evident, that the percentage changes in these quantities shown in Fig. 10 would not account for the observed attenuation effects.

It is further to be noted that the magnetic conditions pictured in Fig. 10 are due to the simultaneous passage through the loading coil winding of an alternating current and a fixed value of direct current. The condition of the iron so far as concerns the superposed

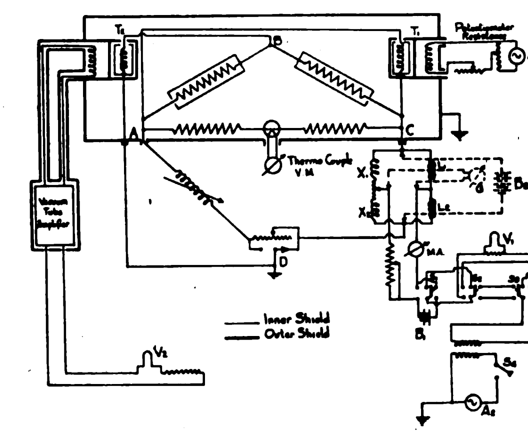

Fig. 12—Circuit of Special Bridge for Determining Flutter Effects

direct current is "static." In a composited telephone circuit, however, the loading coil has its audio-frequency magnetization superposed on iron which is in a "dynamic" state due to the changing magnetization which the telegraph current produces. Such considerations early indicated the necessity for devising means for

observing the effects on the loading-coil characteristics of the superposed magnetization due to telephone and telegraph current when both were passing through rapid cyclic changes.

It has long been known[2] that when an alternating magnetization is superposed on a slowly varying magnetization, the hysteresis loss of the latter is diminished. The energy expended in the iron to diminish this hysteresis must come from a source other than that of the low-frequency current. The flutter effect is recognized then as a manifestation of the interdependence of the high and low-frequency hysteresis losses. If, in any case of superposed magnetizations, there is a suppresion of hysteresis for one magnetization, there is found an accompanying complementary phenomenon, the flutter effect, in the higher frequency magnetization. The present paper we believe to be the first publication of quantitative information on the reaction on the higher-frequency circuit of the hysteresis suppression in the low-frequency circuit.

Mr. John Mills, an engineer of the Bell System whose analysis had indicated the importance of the resistance component, suggested a form of alternating-current bridge to investigate these transient or flutter effects. After considerable experimental work a form of alternating-current bridge was developed for the direct measurement of the effective resistance and inductance of the loading coils, for any desired instantaneous value of the superposed telegraph current.

Description of Flutter Bridge. A simplified diagram of the bridge is shown in Fig. 11. The actual circuit employed is shown in Fig. 12. Two similar coils are tested simultaneously in series. Bridge arms $A\,B$ and $B\,C$ are non-reactive 1000 ohm ratio arms. Arm $A\,D$ consists of a variable inductance of known effective resistance. Arm $C\,D$ comprises the coils which are under test together with an auxiliary circuit in the form of a secondary bridge. The variable resistance between arms $A\,D$ and $C\,D$ may be switched into either arm at will. The alternator A_2 is a source of telegraph current of a frequency of approximately 16 cycles. The recording system comprises an oscillograph and a multi-stage vacuum-tube amplifier through which the oscillograph is connected to the bridge circuit $B\,D$. The audio-frequency generator, A_1, and the recording circuit are connected to the bridge through double shielded transformers T_1 and T_2. The bridge itself is thoroughly shielded electrostatically in order to avoid false balances due to extraneous disturbances or unbalanced admittances to ground. The junction D is grounded so that under conditions of balance the terminals of the recording circuit are at ground potential.

The method of superposing the telegraph current on the secondary bridge circuit of arm $C\,D$ requires some detailed consideration. The magnetic material under investigation is the core of a toroidal inductance coil. Two such similar coils are wound and connected in series. These are designated X_1 and X_2 in the drawing. Two air-coils, L_1 and L_2, also balanced as to inductance and effective resistance, form the other two arms of the secondary bridge. The pair of junctions $X_1\,L_2$ and $X_2\,L_2$ are obviously points of zero difference of potential provided electromotive forces are impressed between the junctions $X_1\,X_2$ and $L_1\,L_2$.

In duplex telegraph operation over telephone lines the telegraph current in the line may have a variety of wave forms, as illustrated by the oscillograms of Figs. 2 and 5. Owing to the presence in the circuit of composite sets the telegraph pulses are rounded off. In the general case the telgraph current may be represented by an alternating current of low frequency.

In the operation of the flutter bridge the equivalent of a telegraph current is derived from a circuit comprising a generator and a battery in series. The generator gives an approximately sinusoidal wave and can be made to generate frequencies from 6 to 25 cycles per second. The e. m. f. of the battery is adjusted to equal the amplitude of the generator voltage. The series connection thus results in a current which pulsates between zero and a maximum positive value. The instantaneous current is, therefore, of the form $i = I_t\,(1 + \sin q\,t)$, where $q = 2\,\pi$ times the frequency of the generator and $2\,I_t$ is the maximum current output. This pulsating current was used instead of an alternating current, because it corresponds more closely to the wave form in half-duplex operation, which is in more general use than is full-duplex operation. It was also found to give more severe flutter than an alternating-current wave.

Special precautions are necessary to maintain the distribution of capacitances in the bridge circuit as a whole unchanged throughout the operation test. For this reason switches S_1 and S_4 are used to cut off the telegraph current without disconnecting any apparatus from the bridge. Switches S_2 and S_3 serve to pass the current through an oscillograph vibrator so that the telegraph wave may be observed and the relative values of the direct and alternating components properly adjusted. The milliameter $M\,A$ measures the telegraph current.

With the bridge circuit described, measurements of the instantaneous changes in inductance and effective resistance could be made with an accuracy of approximately 5 per cent.

In making the test it is necessary to observe the telegraph wave in its time relation to the current through the recording circuit. This is accomplished by having the low-frequency generator direct-coupled to the oscillograph mirror, thus making the telegraph wave "stand" in the field of view.

When the telegraph current is zero and the bridge is balanced to the telephone current, there will be no

2. F'nzi. *E ectrician* Vol. 26, p. 672, 1891, also, Gerosa and Finzi-Rendiconti del R Istituto Lombardo Vol. XXIV fasc. X April 1891.

difference of potential across the terminals $B\,D$. However, as soon as the telegraph current is applied a recurring unbalance is produced. The period of this phenomenon is double the frequency of the telegraph pulse.

It will be recognized that the bridge as described comprises sources of two frequencies, a balanced magnetic system which modulates the higher frequencies by the lower, and a bridge connection which transmits to the recording apparatus only the modulated current.

Operation of Bridge. The actual procedure in making a test is as follows: The main bridge is first balanced with the selected value of audio-frequency current of the desired frequency. The secondary bridge is also balanced for direct current after adjusting the current strength to the desired value. The telegraph current is then adjusted to the required strength and frequency by switching in the oscillograph vibrator V_1 which gives a standing wave on the scale in the oscillograph field of view. The telegraph current

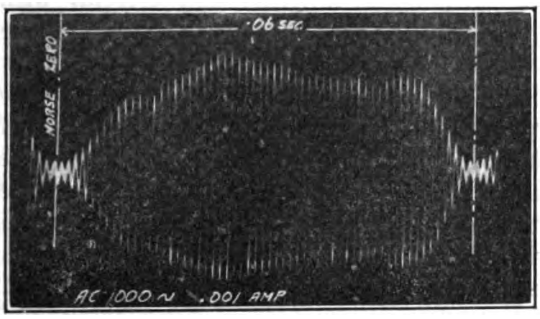

FIG. 13—RECORDER CURRENT WITH BRIDGE BALANCED FOR ZERO POINT OF TELEGRAPH WAVE

is then replaced in the oscillograph (using vibrator V_2) by the amplified current in the recording circuit, which is essentially the unbalanced audio-frequency current modulated by the telegraph current. During this observation switch S_2 is thrown to the right and S_3 to the left.

Fig. 13 is an oscillograph record of the unbalance current and shows the variations in its amplitude during the making of a telegraph "dot," *i. e.,* during one complete pulsation. It will be noted that the two constrictions occurring in the current are separated by a time interval corresponding to the frequency of the telegraph pulses, 16.6 cycles per second.

By suitable adjustment of L and R in the bridge arm $A\,D$, a balance can be obtained corresponding to any point of the telegraph wave, thus giving the instantaneous values of the effective resistance and inductance of the secondary bridge arm $C\,D$ corresponding to each point of the telegraph wave. The difference between these values and those required to balance at zero telegraph current are used to obtain the instantaneous changes in the iron-core coils by means of the following formulas:

$$\Delta R = \frac{\Delta R'}{2} \cdot \frac{(L_1 + L_2 + X_1 + X_2)}{(L_1 + L_2)^2} \qquad (6)$$

$$\Delta L = \frac{\Delta L'}{2} \cdot \frac{(L_1 + L_2 + X_1 + X_2)}{(L_1 + L_2)^2} \qquad (7)$$

where ΔR and ΔL are the changes in effective resistance and inductance respectively of the loading

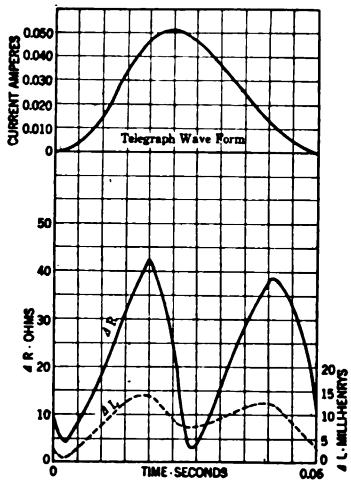

FIG. 14—VARIATION OF INCREMENTS OF EFFECTIVE RESISTANCE AND INDUCTANCE WITH PHASE OF TELEGRAPH CURRENT

coils, L_1 and L_2 are the inductances of the air-core coils, X_1 and X_2 are the inductances of the loading coils, $\Delta R'$ and $\Delta L'$ are the changes in resistance and inductance respectively, required to balance the bridge at the selected point of the telegraph wave.

These equations are an approximation as they neglect the resistance of the coils. This is permissible as the ratio of reactance to resistance in these coils at the test frequencies employed is very large (about 100:1).

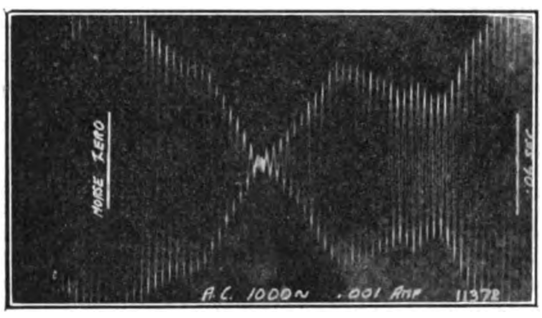

FIG. 15—RECORDER CURRENT WITH BRIDGE BALANCED AT FIRST PEAK OF ΔR CURVE OF FIG. 14.

Using this method the curve of Fig. 14 obtained. It will be seen that the changes from L_0 and R_0 during the interval of a single telegraph pulse take the form of a double peaked curve, the maximum values corresponding to the time in which the telegraph current is experiencing its greatest rate of change, the first when it is increasing and the second while it is decreas-

ing in value. In the upper part of the figure the telegraph wave is shown in its proper time relation to the flutter increments. Fig. 15 is an oscillogram of the recorder current, when the bridge is balanced for the part of the telegraph wave, corresponding to the first peak.

The curve of Fig. 14 shows the increments of effective resistance and of effective inductance during one cycle of telegraph current for a definite value of the high-frequency current. For the purposes of the present investigation it was important to ascertain the effect of varying the values of both the telegraph and the telephone frequency current. This was necessary in order to determine the laws for the variation of

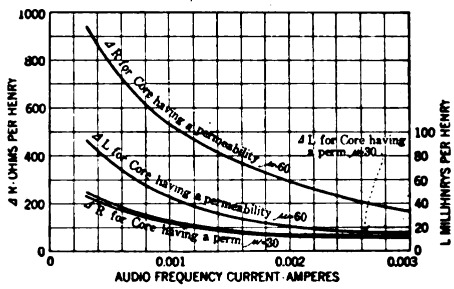

FIG. 16—VARIATION OF FLUTTER WITH TELEPHONE CURRENT

flutter, first with different telephone currents under fixed telegraphic conditions, and second, with different telegraph currents under fixed telephonic current. In making these tests only the peak values were recorded, as these are of the most importance in comparing different core materials for flutter effects. The data given in Tables II, III, IV, and V were thus obtained. The values of increment resistance and inductance are the averages of the two successive peak values.

The hysteresis losses for the 30 and 60-permeability core materials were determined for conditions of zero telegraph current from measurements over a range of telephone frequencies and current strengths. For

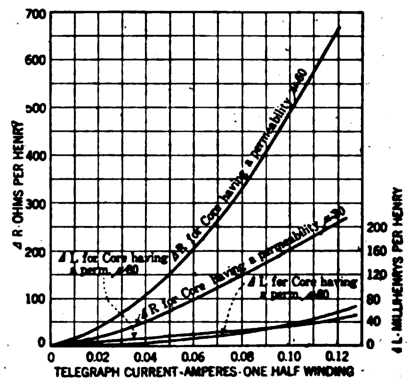

FIG. 17—VARIATION OF FLUTTER WITH TELEGRAPH CURRENT

the telephone conditions of Tables III and V, *i. e.*, 0.001 ampere and 1600 cycles, the total iron loss for the 60-permeability material was found to be 70 ohms per henry, of which 38 ohms is hysteresis loss. For the 30-permeability material the total loss is 37 ohms per henry, of which 17 ohms is hysteresis loss. It will be seen by reference to Table II that the resistance increment (peak value) due to flutter in the 60-permeability material is approximately 14 times the normal hysteresis loss resistance.

From the tabulated data the curves of Figs. 16 and 17 have been plotted. Fig 16 shows the relation of flutter to telephone current, while Fig. 17 shows the variation in flutter for a constant value of telephone current as the telegraph current is increased. The current values used for the latter curves are twice those given in the table for the reason that the telegraph current actually flowed through one-half of the coil winding. It will be noted that in these tests a telephone frequency of

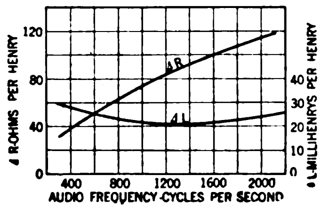

FIG. 18—VARYING AUDIO FREQUENCY

Telegraph current = 16.6 pulsations per second, 0.10 ampere in one line winding. Audio-frequency current, 0.001 ampere.

Curves show peak values.

1600 cycles was used. This frequency was chosen rather than the one usually considered as representative for telephonic measurements (*i. e.* 800 cycles) in order to magnify the flutter values, which increase with the frequency used. This is shown in Fig. 18 and 19, which give the flutter increments for varying telephone and telegraph frequencies respectively.

DISCUSSION OF RESULTS

In the experiments, the audio-frequency magnetizing force had, on the average, a value $H = 0.05$ *c. g. s.*, corresponding to a normal telephone current in the loading coil windings. This is a very small force, yet it exceeds that for which the molecular displacements may, according to Ewing's molecular theory,[3] be taken to be perfectly elastic, *i. e.* without hysteresis. The strength of audio-frequency current used develops only the initial permeability of the iron. The hysteresis loss in this region for hard iron is very small and can be detected only by careful bridge measurements. Such measurements can be used to separate the hysteresis from the eddy-current losses by the method referred to above.

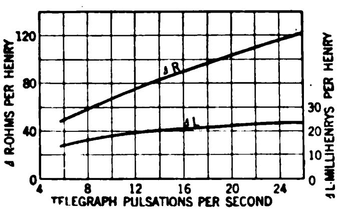

FIG. 19—VARYING TELEGRAPH FREQUENCY

Telegraph current = 0.10 ampere. Audio-frequency current = 0.001 ampere (1600 cycles per second).

Curves show peak values.

Computations based on a loss separation show that the increase in eddy-current loss due to the small increase in high-frequency inductance during the telegraph cycle would account for only a small fraction of the increased effective resistance. The balance of the increase must be charged to an augmented hysteresis loss. That such a loss is due to the high-frequency current assisting the low-frequency current to execute its hysteresis cycle is in accord with the work of previous investigators.

The results of the tests described above are summarized in part by the following empirical equation, which in terms of power, satisfies fairly well the ΔR curves of Figs. 16 and 17.

$$W/L_0 = k\, H_t^{1.6}\, H_{ac}^{\ 1.2}$$

in which,

W = maximum watts increment (taken as the product of ΔR and the square of the current for the corresponding point), for audio-frequency,

H_t = magnetizing force due to telegraph current,

H_{ac} = magnetizing force due to audio-frequency current.

The inference has already been drawn that the increased power loss in the high-frequency circuit represents a transfer of energy from the higher-frequency to the lower-frequency magnetization. It will be interesting therefore to review briefly the work of previous investigators on the subject of superposed magnetization in iron. The earliest work, already referred to, is that of Geroza and Finzi[4], who observed that there was a tendency to suppression of the hysteresis of a direct-current magnetization when alternating-current magnetization was superposed. In their experiments the direct-current magnetization was produced by a coil surrounding an iron wire, the alternating current having its path through this wire. The induction due to the current in the coil gave a "longitudinal" magnetization, while that due to the current in the iron wire produced a "circular" magnetization. These experiments also showed an increased initial slope of the *B-H* curve, indicating a greatly increased permeability of the iron to weak forces.

Maurain[5] in an investigation of the action of the Marconi magnetic detector made experiments in which the specimen was subjected to two longitudinal magnetizations, one due to direct current, the other to an oscillatory current. He found that under proper conditions the hysteresis could be completely suppressed in soft iron.

Probably the most striking experiments involving hysteresis effects were those by Madelung[6], who used a Braun tube to obtain on a flourescent screen the effect of superposing a rapidly oscillating magnetic force on the hysteresis cycle produced by a slowly varying magnetic force.

Goldschmidt[7] investigated the effect of combined longitudinal and circular magnetization, the former being produced by direct current and the latter by an alternating current. He also remarked that the area by which the d-c. hysteresis loop is reduced exceeds that of the normal loop of the superposed circular magnetization. Waggoner and Freeman[8] examined the extent of hysteresis suppression with a superposed alternating longitudinal field for a series of iron-carbon alloys. The results showed the reduction of hysteresis to be proportional to the carbon content.

The present paper has dealt with the reaction in the high-frequency circuit instead of with the previously known effect on the low-frequency magnetization cycle. The basis for our conclusion that the so-called flutter in composited telephone circuits is complementary to a suppression of the hysteresis normal for a magnetization by telegraph currents, appears from the following restatement of our experimental results:

1. The resistance increment is proportional to the frequency of the telephone current.

2. It is proportional for different grades of iron to the hysteresis loss normal for these respective grades.

3. For larger telegraph loops having a greater average slope, the flutter loss increases correspondingly.

The findings of this investigation have been of immediate practical importance in the design of the plant of the Bell system. The fact that flutter depends upon hysteresis has led to the employment of materials of low intrinsic permeability in the coils used for loading the important long toll lines. The cross-sectional area of the core has been proportioned so as to work the iron at very low flux densities. These requirements affect also the design of other iron-cored induction coils and transformers which are used in circuits carrying currents of different frequencies.

For long loaded cable circuits there has been developed a telegraph system which has permitted a large reduction in the magnitude of the operating current. As a result of these factors the simultaneous operation of telegraph and telephone over a loaded cable circuit is satisfactorily free from flutter. A similar condition has also been obtained for the open wire lines.

It has been suggested that a current of frequency above the telephone range be superposed on the loaded lines to suppress the hysteresis and thereby reduce the iron losses for the telephone currents. This would tend to reduce also the flutter caused to the telephone currents by telegraph operation. This proposal was considered some years ago, but has difficulties in the way of its practical application. For instance, the frequency of the superposed current must be much higher than the frequency in the important telephone range to be effective. This would require that the spacing of the loading coils be decreased to transmit the higher-frequency waves, because the upper frequency limit of the transmission range of a coil loaded circuit is, for a given inductance per mile, inversely proportional to the spacing of the loading coils. There is also the problem of transmitting over very long circuits the amount of high-frequency power necessary to effectively suppress hysteresis.

Reference has been made to the presence of hysteresis suppression in the Marconi magnetic detector. The test results discussed above indicate that this suppression causes a power loss in the high-frequency circuit, which we have termed "flutter." These two effects, for flux densities well below saturation, are accompanied by a material change in permeability to the slowly varying magnetizing force. This change in permeability, it should be noted, is not merely that due to a shift along the normal magnetization curve, but results from a change in the form of the magnetization curve itself. The principle of operation of the various forms of magnetic amplifier and detector for radio telephony and telegraphy is such as to involve all of these actions.

The experiments described in this paper deal with two longitudinal magnetizations of different frequency and apply directly to conditions encountered in the telephone and telegraph plant. The determination of the actual form of the magnetization curve under the action of two magnetizations presents an interesting field for further investigation. The most direct mode of attack appears to be the use of the Braun tube to obtain the dynamic magnetization curve in a manner generally similar to that employed by Madelung. Such an investigation could well be directed toward obtaining accurate data as to the relation of the total hysteresis with two or more magnetic forces acting simultaneously to the hysteresis for each force acting alone. The investigation should include an examination of hard as well as soft iron, and determine the effect on B_{max} for both forces as well as the change in area of the hysteresis loops. With a number of superposed magnetic forces differing in their magnitudes and rates of change the further problem is presented of determining the interaction of any two of the forces in the presence of the others.

THE MIDWINTER CONVENTION

As previously announced, the 9th Midwinter Convention of the A. I. E. E. will be held in New York City, February 16-18, in the Engineering Societies Building.

In addition to the technical sessions, the Entertainment Committee has provided for visits to various power plants on Wednesday afternoon, a dinner-dance at the Hotel Astor Thursday evening. The Edison Medal will be presented to Dr. Pupin Friday evening, and will be followed by a lecture by the medalist.

The registration office on the ground floor of the building will be open at 1.00 p.m. The opening technical session will be held in the main auditorium, and all of the other technical sessions in assembly room No. 1 on the fifth floor. The Edison Medal ceremonies and the lecture Friday evening will be in the auditorium.

The entire program is as follows:

PROGRAM

Wednesday Afternoon, February 16th

Registration office open, 1.00 p.m.
Board of Directors' Meeting, 3.30 p.m.
Inspection of local electrical plants.

Complete details will be furnished in the announcement to be mailed to the membership.

Wednesday Evening

Auditorium

TECHNCAL SESSION, 8:15 p.m.

Opening address by President Berresford.

"Present Day Practise Limitations of Oil Circuit Breakers" by H. R. Woodrow, Engineering Department, Stone & Webster.

"High-Current Tests on High-Tension Switchgear" by Philip Torchio, Chief Electrical Engineer, New York Edison Co.

Moving pictures and oscillograph records of switches at instant of failure will be shown.

Thursday Morning, February 17th

Assembly Room No. 1 Fifth Floor

TECHNICAL SESSION, 10:30 a.m.

"The Maximum Safe Operating Temperature of Low-Voltage Paper-Insulated Cables" by W. A. Del Mar, Chief Engineer, Habirshaw Electric Cable Co.

"Permissible Operating Temperatures of Impregnated Paper Insulation in which the Dielectric Stress is Low" by Philip Torchio, Chief Electrical Engineer, NewYork Edison Co.

"Permissible Operating Temperatures of Impregnated Paper Insulation in which the Dielectric Stress is Low" by D. W. Roper, Superintendent of Street Department, Commonwealth Edison Co.

Notes on "The Effect of Heat on Impregnated Paper from Cable Insulation" by W. S. Clarke, Engineer, Wire and Cables, General Electric Co.

"The Effect of Heat Upon Paper Insulation" by H. W. Fisher, Chief Engineer, Standard Underground Cable Co., and R. W. Atkinson, Assistant to Chief Engineer, Standard Underground Cable Co.

"Permissible Operating Temperatures of Impregnated Paper Insulation in which the Dielectric Stress is Low" by L. L. Elden, Electrical Engineer, The Edison Electric Illuminating Company of Boston.

Thursday Afternoon

Assembly Room No. 1, Fifth Floor

TECHNICAL SESSION 2.30 p.m.

"Carrier-Current Telephony and Telegraphy" by E. H. Colpitts, Assistant Chief Engineer, Western Electric Co., and O. B. Blackwell, Transmission Development Engineer, American Tel. & Tel. Co.

"Some Phases of Railroad Telegraph and Telephone Engineering" by Stanley Rhoads, Telegraph and Telephone Engineer, New York Central Lines.

Thursday Evening

Dinner Dance at Hotel Astor, 7:00 p.m. For details see under "Entertainment" following.

Friday Morning, February 18th

Assembly Room No. 1, Fifth Floor

TECHNICAL SESSION, 10:30 a.m.

"Regulation of Frequency for Measurement Purposes" by B. H. Smith, Engineering Department, Westinghouse Elec. & Mfg. Co.

"Measurement of Relative Eddy Current Losses in Stranded Cables" by J. A. Cook, Assistant Chief of Laboratory. New York Edison Co.

"An Electromagnetic Device for Rapid Schedule Harmonic Analysis of Complex Waves" by F. S. Dellenbaugh, Jr., Secretary, Research Division, Electrical Engineering Department, Massachusetts Institute of Technology.

"The Limitations of the Stopwatch as a Precision Instrument" by A. L. Ellis, Assistant Director, Thompson Laboratory, General Electric Co.

Friday Afternoon

Assembly Room No 1, Fifth Floor

TECHNICAL SESSION, 2:30 p.m.

"Short-Circuit Current of Induction Motors and Generators" by R. E. Doherty and E. T. Williamson, both of General Electric Co.

"Hysteresis Effects with Varying Superposed Magnetizing Forces" by W. Fondiller, Engineering Department, Western Electric Co. and W. H. Martin, Department of Development and Research, American Tel. & Tel. Co.

"Longitudinal and Transversal Heat Flow in Slot-Wound Armature Coils" by Carl J. Fechheimer, Research Engineer, Westinghouse Electric & Mfg. Co.

Friday Evening

AUDITORIUM

Presentation of the Edison Medal to Dr. M. I. Pupin,

Lecture, "Wave Transmission" by M. I. Pupin.

Discussing the losses of energy occasioned by the transmission of sound waves, electric waves and luminous waves through material media.

The lecture will be illustrated by experiments.

ENTERTAINMENT

Dinner—Dance

A dinner-dance will be held at the Hotel Astor, Broadway and 44th Street, New York, Thursday evening, February 17, 1921, at 7:00 o'clock. The purpose of the dinner-dance is to provide a social function for the entertainment of the members and their guests in attendance at the convention.

An informal reception will precede the dinner and prompt attendance is desired in order that the Entertainment Committee's arrangements may be carried out as planned.

The subscription price is $6.00 per person.

The tables will accommodate eight or ten persons each. Members are requested to make up their own tables and to state their seating preference to the committee. Communications should be addressed to the Committee on Entertainment, A. I. E. E., 33 West 39th Street, New York.

FUTURE A. I. E. E. MEETINGS

MARCH, NEW YORK

The 368th meeting of the A. I. E. E. will be held in New York, Friday evening, March 11th in the Engineering Societies Building.

The program will be under the auspices of the Power Stations Committee, and the subject of the meeting will be "Developments in Conversion Apparatus for Edison Systems." One main paper will be presented and will be followed by several prepared discussions.

APRIL, PITTSBURGH

The 369th meeting of the A. I. E. E. will be held on Saturday, April 16, 1921, in Pittsburgh, Pa. This will be a joint meeting with the Association of Iron and Steel Electrical Engineers and the general subject of the meeting will be "The Power Supply of the Pittsburgh District in Relation to the Steel Mill Industry."

Two papers will be presented on behalf of each of the participating societies. The A. I. E. E. papers are on the "New Colfax Station of the Duquesne Light Company—Electrical Features" by D. L. Galusha and the "Mechanical Features" by C. W. E. Clarke. The A. I. & S. E. E. papers are on the "Problems of Conversion from 60 Cycles to 25 Cycles" by B. G. Lamme, and "Some Results in the Change of 60-Cycle to 25-Cycles Energy by J. E. Fries.

The program includes a visit to the Colfax plant in the morning followed by luncheon; an afternoon session at which the papers on the Colfax plant will be presented and discussed; informal dinner, and an evening session at which the papers by Messrs. Lamme and Fries will be presented.

MAY, NEW YORK

The 370th meeting of the A. I. E. E. will be held in the Engineering Societies Building, New York, May 20, 1921. This is the Annual Meeting of the Institute, at which the result of the annual elections is announced and the report of the Board of Directors is presented.

FUTURE SECTION MEETING

Schenectady.—March 18, 1921. Subject: "European Economic and Industrial Situation." Speaker: Mr. D. B. Rushmore.

NEW YORK SECTION MEETING

On Friday evening, February 25, at 8 p. m., the New York Section of the Institute will hold a meeting in the Auditorium of the Engineering Societies Building, 33 West 39th St., New York. Dr. Saul Dushman, Research Laboratory General Electric Company, Schenectady, will deliver a lecture entitled "Habits of the Electron."

This lecture should appeal to those engineers who have not had time to go into the electron theory in all its details as it will be a presentation of the subject in as non-technical a manner as possible and will probably be accompanied by experimental demonstrations.

AKRON-CLEVELAND MEETING, JANUARY 14, 1921

The 366th meeting of the Institute was held in Akron and Cleveland on January 14th under the auspices of the Akron and Cleveland Sections and the Industrial and Domestic Power Sub-Committee on the Rubber Industry.

The Board of Directors met in Akron in the morning, and the Industrial and Domestic Power Committee also held a well attended meeting at the same time. Later in the morning special cars arrived from Cleveland bringing many of the Institute members from that city and vicinity. At noon, the 200 or more members and others present were the guests of the B. F. Goodrich Company at an excellent luncheon served in the cafeteria of that company. The lunch was preceded by a brief and exceedingly interesting address relating to the electrification of the Goodrich Plant by Mr. Vance of that company, followed by some interesting motion pictures.

After luncheon, those present were conducted in small groups by guides through the plant of the B. F. Goodrich Company, after which special cars were provided for conveying the party to Cleveland, where an informal dinner was served at the Hotel Statler at 6:30 p. m. Chairman A. M. MacCutcheon of the Cleveland Section presided, and a brief address was made by President Berresford.

The technical session began at 8:15 p. m., at which the paper previously published in the Institute JOURNAL on "Application of Electric Power in the Rubber Industry," prepared by the Sub-Committee on the Rubber Industry of the Industrial and Domestic Power Committee, was presented. A very interesting discussion followed and the meeting adjourned about 11:10 p. m.

The dinner and the technical session were held at the headquarters of the Cleveland Engineering Society, where every facility was provided for the comfort of those present. The officers of that society and the members of the Committee of Arrangements for the meeting are to be congratulated upon the satisfactory manner in which the entire program for the day and evening was planned and carried out.

A. I. E. E. DIRECTORS MEETING, JANUARY 14, 1921

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at the headquarters of the Akron Chamber of Commerce, Akron, Ohio, Friday, January 14, 1921, at 9:45 a. m.

There were present: President A. W. Berresford, Milwaukee;

Vice-Presidents Charles S. Ruffner, New York, Charles Robbins, Pittsburgh, E. H. Martindale, Cleveland; Managers W. A. Del Mar, L. F. Morehouse, E. B. Craft, New York, F. F. Fowle, Chicago, James F. Lincoln, Cleveland; Secretary F. L. Hutchinson, New York.

The Board ratified the approval of the Finance Committee of monthly bills amounting to $14,929.21.

Reports were presented of meetings of the Board of Examiners held November 29, 1920, and January 3, 1921; and the actions taken on applications at those meetings were approved. Upon the recommendation of the Board of Examiners the following action was taken upon pending applications: 169 Students were ordered enrolled; 119 applicants were elected to the grade of Associate; 14 applicants were elected to the grade of Member; 18 applicants were transferred to the grade of Member; 3 applicants were transferred to the grade of Fellow.

The Meetings and Papers Committee reported upon plans for the following meetings: Midwinter Convention, February 16-18, New York, the program of which appears elsewhere in this issue; March 11, New York under the auspices of the Power Stations Committee—topic, "Developments in Conversion Apparatus for Edison Systems"; April 16, Pittsburgh, joint meeting with Association of Iron and Steel Electrical Engineers; May 20, Annual Meeting, New York.

The Board reaffirmed the action of the Board of Directors on February 26, 1914, to the effect that no committee meetings be held at hours which will conflict with technical sessions during Institute meetings or conventions. The Directors also voted that Institute committee meetings should in general be held during the latter, rather than the earlier, part of the week, whenever practicable.

The Committee on Coordination of Institute Activities reported the various actions taken by it at its meeting on December 4, 1920, including a recommendation that the policy be established of awarding prizes for the most worthy papers presented before the Institute. The Board approved the recommendation in principle and referred the matter back to the committee for the purpose of formulating a plan of procedure, including the method of making the awards, etc. The committee also recommended that in the future the Edison Medal and any other medals that may be awarded by the Institute, be presented to the medalists at the Midwinter or Annual Convention, preferably the former whenever feasible. This recommendation was approved.

A report was presented from the Edison Medal Committee announcing that the committee had awarded the Edison Medal for the year 1920 to Dr. Michael I. Pupin, for "his work in mathematical physics and its application to the electrical transmission of intelligence." (Arrangements have been made to present the medal to Dr. Pupin during the Midwinter Convention, on Friday evening, February 18.)

Mr. E. W. Rice, Jr., was reappointed a representative of the Institute on the Engineering Foundation Board for a term of three years, commencing February 10, 1921.

A communication from Mr. L. P. Alford, Temporary Executive Secretary of the American Engineering Council, was presented, calling attention to the fact that the employment activities had been transferred to the new organization and were being carried on by a temporary board consisting of the secretaries of the National Societies of Mining, Mechanical and Electrical Engineers; that the American Engineering Council had taken over the office of old Engineering Council in the McLachlen Building, Washington, where Mr. A. C. Oliphant is at present in charge; as Acting Assisting Secretary: and that a temporary office has been established at the Engineering Societies Biulding, New York City. Another communication from Mr. Alford gave the personnel of the principal committees of American Engineering Council already appointed, the chairmen of these committees being as follows: Constitution and By-Laws, Mr. W. B. Powell; Membership and Representation, Mr. J. F. Oberlin; Public Affairs, Mr. J. Parke Channing; Finance, Mr. Wm McClellan; Procedure, Mr. Calvert Townley; Publicity and Publications, Mr. L. P. Alford.

Secretary Hutchinson reported that at a meeting held January 13 the Secretaries of the four Founder Societies acting as the Board in control of the employment activities, had taken all necessary actions to terminate the existence of the former Engineering Societies Employment Service, this activity having been transferred, by action of the various boards of directors concerned, to the new American Engineering Council. The Secretary also reported that the Secretaries of the National Societies of Mechanical, Mining and Electrical Engineers were, upon request of the American Engineering Council, acting as a temporary board in charge of the employment activities; it being understood that at a later date this board will be enlarged by the inclusion of the secretaries of the various societies that are members of The Federated American Engineering Societies. The activity is continuing on practically the former basis, the finances being provided from the treasury of the American Engineering Council.

A final report was presented under date of November 27 from Charles F. Scott, Chairman of the Institute delegation upon the Joint Conference Committee; and the following actions were taken:

RESOLVED: That the report of the Chairman of the Institute's delegation on the Joint Conference Committee of the Founder Societies, under date of Novenber 27, 1920, be hereby accepted; and be it further

RESOLVED: That the Board of Directors of the American Institute of Electrical Engineers hereby places on record its hearty appreciation of the valuable services rendered to the Institute and the engineering profession generally by Messrs. Charles F. Scott, L. T. Robinson, and Calvert Townley in their capacity as representatives of the Institute upon the Joint Conference Committee representing the four Founder Societies, culminating in the recent organization of The Federated American Engineering Societies and the American Engineering Council.

RESOLVED: That the Board of Directors of the American Institute of Electrical Engineers hereby places on record its hearty appreciation of the valuable services to the engineering profession rendered by Mr. Richard L. Humphrey in his capacity as Chairman of the Joint Conference Committee of the Founder Societies, the efforts of which committee resulted in the recent organization of The Federated American Engineering Societies and its governing body, the American Engineering Council.

Mr. Ruffner reported upon the actions taken at the final meeting of Engineering Council, which has now terminated its existence, it being understood that all of its activities will be continued by the recently organized American Engineering Council.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

INTEREST IN THE SHELDON MEMORIAL FOUNDATION GROWING

Interest and activity are growing in the Sheldon Memorial Foundation. The aim is to establish a fund of $100,000, the annual income of which is to go toward the founding of a chair in electrical engineering at the Brooklyn Polytechnic Institute, where Dr. Sheldon spent the thirty years preceding his death in organizing and enlarging the department of electrical engineering.

The movement for a memorial foundation was authorized and started at the Sheldon memorial exercises held last November in the Engineering Societies Building, under the direction of a committee of which T. C. Martin was chosen chairman.

An active campaign was started by these representatives in December to secure pledges and funds. Pledges from members of the professional societies, and from the Polytechnic trustees, alumni, students and friends, have already been received and are in excess of $25,000. Of this upward of $6,000

has so far been paid in. Now that the holidays are past, an intensive campaign is being pushed both in the electrical engineering field and in Brooklyn. Many contributions and pledges are being sent in voluntarily.

The treasurer of the fund, Charles E. Potts, is one of Dr. Sheldon's former students and a trustee of the Polytechnic Institute. He is receiving pledges and contributions daily at his office at 81 Franklin Street, New York City.

TELEGRAPH MEN WHO ARE MEMBERS OF THE AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS

The Blue-book of the American Institute of Electrical Engineers shows the names of 535 telegraph and telephone engineers as Fellows, Members or Associates.

A few of those directly engaged in telegraph work, who are identified with the Institute are:

In the service of the Western Union Telegraph Company: J. P. Edwards, R. E. Chetwood, H. W. Drake, G. M. Yorke, A. Lyons, M. H. Clapp, L. B. Bass, W. N. Fashbaugh, W. W. Drew, A. S. Dana, F. E. D'Humy, D. C. Brundage, E. R. Shute, A. Z. Mample, G. W. Janson, Everett Harvey, Thomas C. Harlan, L. H. Williams, M. A. Frye, J. E. Jenkins and J. W. Milnor.

In the service of the Postal Telegraph-Cable Company: J. P. O'Donohue, H. C. Shaw and John H. Mayer.

Others are: H. Hulatt, manager of telegraphs, Grand Trunk Railway, Montreal; Charles E. Davies, general superintendent of traffic, Great North Western Telegraph Company, Toronto; G. A. Cellar, general superintendent of telegraph, Pennsylvania Railroad, Philadelphia; Stanley Rhoads, telegraph and telephone engineer, New York Central Lines, New York; I. C. Forshee, electrical engineer, Pennsylvania Railroad, Philadelphia; H. L. Graham, Baltimore and Ohio Railroad, Jenkins, Ky; L. Behner, assistant superintendent of telegraph and signals, Pennsylvania Railroad, Pittsburgh, Pa.; G. H. Mayer, superintendent of telegraph, Soo Line, Stevens Point, Wis.; W. R. Birt, Southern Pacific Pailroad; M. A. Noss, engineer, Telepost Company, New York, and H. L. Krum, of the Morkrum Company, Chicago.

Telegraph engineers, wire chiefs and testing and regulating assistants who wish to identify themselves with the Institute may obtain application forms from Donald McNicol, chairman of the Telegraphy and Telephony Committee, 253 Broadway, New York.—*Telephone and Telegraph Age.*

AMERICAN ENGINEERING COUNCIL

ACTIVITIES ASSUMED

Beginning with the first of the year the transfer of activities of Engineering Council and the Engineering Societies Service (Employment) Bureau was made to American Engineering Council.

This means that American Engineering Council now has an office in Washington at the McLachlen Bldg., 10th and G. Sts., with Mr. A. C. Oliphant as acting Assistant Secretary in charge.

The Engineering Societies Service Bureau is being maintained in the Engineering Societies Building, 29 W. 39th St., New York City with Mr. Walter V. Brown in charge. At the outset it did not seem practicable to develop the permanent organization that is to direct this very important activity and which has such a close relationship with the secretarial responsibilities of the Member Societies of The Federated American Engineering Societies. Up to this time this service has been under the direction of the secretaries of the four Founder Societies, so temporarily it would seem wise to request the Secretaries of the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers and the American Institute of Electrical Engineers to form a Committee on Management to conduct the Service Bureau until such time as a permanent organization, under American Engineering Council, can be effected.

The Committee on Procedure of the Executive Board of American Engineering Council, when voting to take this employment service, specified that the applicants should be arranged in two groups, first, those who are members of Member Societies of The Federated American Engineering Societies, and second, all others. The text of the resolution in this regard reads as follows:

RESOLVED: That the Employment Bureau be continued by American Engineering Council on and after January 3, 1921, and that the Secretaries of the American Institute of Mining & Metallurgical Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers be invited to act as Managers until such time as a more comprehensive plan can be formulated.

RESOLVED: That applicants for employment be divided into two classes—Preferred and Ordinary, the Preferred Applicants being those who are members of constituent societies of American Engineering Council and the Ordinary applicants all others.

It was thought that the best means to communicate with the secretaries of the Member Societies of The Federated American Engineering Societies would be by means of a regularly issued bulletin listing the positions open. This plan is to be carried into effect very shortly.

The American Engineering Council has temporary headquarters in New York City, and here, as well as in Washington, will be glad to serve the Member Societies and the individuals of Member Societies.

STANDING COMMITTEES

At the meeting of the Executive Board of American Engineering Council on December 17th, President Hoover announced the appointment of the following standing committees:

Constitution and By-laws. W. B. Powell, Chairman, C. F. Scott, D. S. Kimball.

Finance. Wm. McClellan, Chairman, E. Ludlow, C. Townley, L. W. Wallace, Ex-Officio.

Membership and Representation. J. F. Oberlin, Chairman, L. W. Wallace, A. S. Dwight.

Procedure. Calvert Townley, Chairman Herbert Hoover, Ex-Officio, W. E. Rolfe, D. S. Kimball, L. Parke Channing, L. W. Wallace. L. P. Alford.

Public Affairs. L. Parke Channing, Chairman, Fred J. Miller, L. B. Stillwell.

Publicity and Publications. L. P. Alford, Chairman, H. W. Buck, H. E. Howe.

At this meeting of the Executive Board the President was requested to invite the following existing committees of Engineering Council to continue their work and act as committees of American Engineering Council:

Classification and Compensation of Engineers, Cooperation with American Institute of Architects, National Board for Jurisdictional Awards in Building Industry, Military Affairs Committee, New York State Government Reorganization, Patents Committee, Payment for Estimating.

Russian-American Committee, Types of Government Contracts.

A Committee on the Elimination of Waste in Industry is being formed and the personnel of this committee will be announced later.

ENGINEERING COUNCIL

CLASSIFICATION AND COMPENSATION OF ENGINEERS

The Committee on Classification and Compensation of Engineers, which was reorganized on May 17 last, made a comprehensive survey of its activities and accomplishments in its final report to Engineering Council of December 6, 1920. The report, slightly condensed, follows:

Review of Activities in 1919

The Committee was originally organized early in April, 1919, and on December 18, 1919, it presented to Engineering Council a comprehensive review of the fields covered by the inquiry up to that time, and on the latter date Council adopted the classification. At that time five recommendations were made by the Committee, comprising the following:

1. The adoption of a classification of engineers in governmental and railroad services, and a tentative plan for compensation and promotion;
2. Advocacy of legislation for the registering of engineers;
3. Obtaining the views of heads of engineering bureaus and services as to the reasonableness of the proposed schedule of compensation;
4. Printing of an abstract of the report of the committee;
5. Appropriation of $10,000 for continuance of the Committee's work in 1920.

After prolonged discussion it was voted by the Council:

That the first recommendation of the committee be adopted, that the third, fourth and fifth recommendations be referred to the Executive Committee with power, except as to adoption of a plan for compensation of engineers (the Executive Committee later appropriated $3000 for use of the Committee), and that the classification proposed by the committee for engineers in governmental service be given prompt publicity.

Activities in 1920

The second stage of the work was organized with a view to bringing about a successful outcome through the stimulation of discussion and by obtaining publicity.

During the year 1920 a campaign was inaugurated on behalf of the classification adopted by Engineering Council with a view toward securing its general adoption and recognition as a standard for all branches of engineering service. To this end a communication together with an abstract of the December, 1919, report of the Committee was addressed during June and July,

(a) To the Secretary of each of 125 National, State and Local engineering or technical societies and of 24 Local Sections of the American Society of Civil Engineers, requesting each to endorse formally the classification, and to give the Committee the benefit of the views of the society or association and of its individual members as to the suitability of the scale of compensation and of the employment policy tentatively suggested,

(b) To each Chief Engineer of 52 engineering bureaus in the Federal Service, of 91 in State service, and of 99 in Municipal service, with a request for advice as to the practicability of immediately enforcing the classification, and as to the suitability of the scale of compensation and of the employment policy tentatively suggested, and

(c) To Governors of all States, to the Mayors of 69 leading cities, and the 5 Borough Presidents of New York City, 58 Secretaries of Civil Service Commissions, and a few non-technical heads of various Federal, State and Municipal deparments having jurisdiction over engineering work, urging official recognition of the classification, and asking for views as to the suitability of the scale of compensation and of the employment policy tentatively suggested.

From the 654 societies, associations and individuals addressed, 116 replies and acknowledgments have been received. These are distributed as shown in Table I.

TABLE I

	Addressed	Replying
Engineering Societies		
Society Secretaries	125	56
Local Sections Am. Soc. C. E.	24	9
Federal Service		
Bureau Heads	58	13
Engineering Heads	52	8
U. S. Civil Service Commission	1	..
President, Board of Commissioners, Washington, D. C.	1	..
State and Municipal Services		
Governors	48	3
Mayors (69 plus 5 Borough Presidents of N. Y. C.)	74	3
Civil Service Commissions	57	10
Engineering Heads of State Bureaus	91	5
Engineering Heads of Municipal Bureaus	99	8
Miscellaneous and Unclassified		
Various Individuals	24	1
Total	654	116

Copies of the communications sent out, mailing lists, and detailed summaries of replies are given in Appendices 1, 2 and 3. Endorsements and constructive criticisms are given in Appendices, 4, 5 and 6.

Summary of Canvass of Technical Societies

An analysis of the replies from society secretaries developed the following facts:

1. That to date the following named Societies, 13 in all, have endorsed the classification by formal action of the society as a whole or by action of its governing board,

   Albany Society of Civil Engineers,
   American Institute of Electrical Engineers,
   American Society for Testing Materials,
   Associated Engineering Societies of St. Louis,
   Colorado Society of Engineers,
   Engineering Association of Nashville,
   Engineers' Club of Columbus,
   Illinois Society of Engineers,—(Tentative Approval)
   The Municipal Engineers of the City of New York,
   The Society of Municipal Engineers of Philadelphia,
   Oregon Technical Council,
   St. Louis Section, Am. Soc. C. E.,
   Washington, (D. C.) Society of Engineers;

2. That of these 13 societies, 11 have adopted a compensation schedule of which 7 accepted the one proposed by the Committee, and 4 have recommended a higher schedule;
3. That 22 societies, including three founder societies have endorsement of the report of the Committee under consideration;
4. That action cannot be taken on the request of the Committee by many of the State and local societies before the winter of 1921 due to the fact that these societies have but one meeting a year;
5. That 18 societies of those addressed will not act in the matter on the ground that the subject is outside the scope of the organization or that the society does not feel qualified to voice an opinion;

Conclusions Drawn from General Canvass

An analysis of the replies received from all sources shows:

1. That endorsement of the classification is unanimous;
2. That where opinions have been expressed regarding the salary schedule, the proposed schedule has generally been endorsed, although it has been criticised on the one hand, on the ground that the compensation provided for the lower grades is

nadequate, while on the other hand, this same criticism has been made regarding the compensation for the higher grades;

3. That in those bureaus or departments where increases have been effected, the greatest increases in every case have gone to those in the lower grades, while only small increases or none at all have gone to the upper grades;

4. That a number of Federal officials and bureau chiefs, on the ground of expediency, are of the opinion that the work of the Congressional Joint Commission, although far from what is desired, should be supported, because through the setting up of a rational classification, it is clearly a step in advance of prevailing conditions;

5. That Civil Service Commissions especially have received the classification with favor;

6. That education of legislators and the general public to the important and indispensable services performed by the engineer is necessary;

7. That in many cases, salaries and titles in public service are fixed by statutes and cannot be changed without legislative action;

8. That many of the officials and engineers addressed fail to appreciate the fundamental character, the simplicity and the universal applicability of the classification proposed;

9. That there is no objection to the use of the terms, "Aid" and "Sub-Professional," on the grounds, respectively, that they do not convey the idea of an engineering engagement, and that they are distasteful to those without technical education or attainments. The former is evidently due to confusion of a *title* and a *grade*, and failure to appreciate that under the proposed classification, it is still possible to retain suitable titles for the positions occupied;

10. That the classification has actually been put into effect in the engineering bureaus of two cities, by one State Engineering Board, and by one city Civil Service Board, and that its adoption by another State Civil Service Commission is under consideration;

11. That engineering societies are not fully awake to the necessity of cooperation in this movement in order to make it successful;

12. That for proper stimulation of this movement, it is necessary to establish personal contact with representative engineers in various parts of the country and to impress upon each individual engineer his personal responsibility for bringing this subject to the attention of the public, in part through the proper upholding of the dignity and importance of the profession and in part through the assertion of the individual right to expect a suitable remuneration for valuable service.

Special Reports and Publicity Work

Part of the original program was carried out in that the services of Mr. Edmund I. Mitchell were engaged in conjunction with Engineering Council to handle the detail features of the work, to make investigations, and to advance the cause in such manner as could be done from the headquarters in New York. In his capacity as assistant Secretary, the Committee wishes in this connection to attest to the energy and thoroughness with which he has conducted this as well as the other branches of its work.

The Committee is of the belief that the campaign of education that it has conducted, has produced more and better results than the returns at hand indicate, and that its influence has reached those of whom it has no knowledge. The Committee has no method of measuring the results of the publicity work it has done, nor of the extent to which its recommendations have been followed by industrial concerns and engineering corporations.

Many copies of the report of December 1919 have been distributed in response to requests received by the Engineering Societies Service Bureau, and it has recently come to light that this report is being used extensively by the Vocational Guidance Department of the International Committee of the Y. M. C. A.

The California State Civil Service Commission has used our classification as the basis of an inquiry, concerning salaries for engineering positions paid by public and private organizations, which it is now conducting to determine what compensation should be paid by that State for different classes and grades of service.

The special reports and publicity items issued by the Committee are collected in Appendix 10, and an index of those published is given in Appendix 11.

While the work of the Committee has been hampered by lack of personal contact with influential forces in various sections of the country, several of its members have presented the subject before engineering bodies. The Chairman and Mr. Merrill have addressed the American Society of Civil Engineers, and the American Association of Engineers. The Chairman has also appeared before the Municipal Engineers of the City of New York, and the Brooklyn Engineers Club. The Secretary, Mr. Baker, has talked to engineering bodies in Boston, Rochester, Columbus and New York City.

Federal Service

In Appendix 7 is given a special report on the Federal Service, prepared under the direction of Mr. Merrill, Chairman of that Sub-Committee. Based upon the conclusions drawn from this report, the Committee believes that the present time is opportune to urge upon Congress an immediate radical revision upward of salaries paid for engineering service in order to arrest the disintegration of the engineering staffs of the National Government now progressing so rapidly. Revised compensation schedules should be based, in so far as practicable, upon the schedule suggested by the Committee.

Railroad Service

A special report of the Railroad Sub-Committee composed of Messrs. Morse and Parsons, is given in Appendix 8. The Committee recommends, in view of the suggestions made therein, that its successor confer with a similar Committee of the American Railway Engineering Association for the purpose of considering the practicability of adapting Engineering Council's classification to the railroad service.

Special Studies

During the year a special investigation has been conducted by Mr. R. S. Parsons to determine what relation, if any, exists between engineering charges and cost of work supervised. The results of this investigation are given in Appendix 9. The Committee is not prepared at this time to do more than recommend that this investigation be continued over as wide a field as practicable to the end that definite conclusions may be reached as to the practicability of fixing compensation on this basis.

Insufficient information has come to hand to enable the Committee to formulate an employment policy. Changing economic conditions make it unwise at this time to attempt to revise the proposed salary schedule put forth a year ago. These questions, along with others left open for discussion in our report of December, 1919, and new ones which have arisen during the year, will have to be left to our successors for further study.

Recommendations

After a careful survey of the whole subject, the Committee recommends:

1. That Engineering Council urge the appropriate Congressional Committee to take favorable action in the matter of providing for an immediate increase in the compensation of the engineering staffs of the Federal Government and to base this action, in so far as practicable, upon the compensation schedule suggested by the Committee on Classification and Compensation of Engineers;

2. That such Committee as may hereafter be constituted, be instructed to confer with a similar committee of the American Railway Engineering Association for the purpose of bringing about the acceptance of a common standard for the classification of engineers;

3. That owing to its vital importance the work of this Committee be continued by some suitable agency;

4. That the investigation to determine the relation between engineering charges to cost of work supervised be continued by such committee as may henceforth take over the work of this Committee:

5. That the present Committee on Classification and Compensation of Engineers be discharged.

Appendices*

The following appendices are made part of this report:

1. Mailing list, copies of letters sent to Society Secretaries, and summary of replies.
2. Mailing list, copy of letter sent to Engineering Heads of Federal, State and Municipal Bureaus, and summary of replies.
3. Mailing list, copy of letter sent to Governors, Mayors, Civil Service Commissions, etc., and summary of replies.
4. Endorsements by and constructive criticism from Societies.
5. Endorsements by and constructive criticism from the Federal Service.
6. Endorsement by and constructive criticism from State and Municipal Services.
7. Report of Federal Sub-Committee.
8. Report of Railroad Sub-Committee.
9. Study of relation of engineering charges to cost of work supervised.
10. Collection of reports and articles given publicity.
11. Index of published articles.

Respectfully submitted
(signed) ARTHUR S. TUTTLE,
Chairman
(signed) CHARLES WHITING BAKER,
Secretary

*Note: Any or all of the appendices will be sent upon request to Engineering Council, 33 West 39th Street, New York.

NATIONAL SERVICE DEPARTMENT

Excerpts from the final report of M. O. Leighton, of the National Service Department, Washington, D. C., to Engineering Council, follow:

December 6, 1920.

The National service work of the Washington office is increasing, and if and when its functions are turned over to the American Engineering Council, the latter will apparently catch the work at high tide.

Requests for information and assistance from the engineers of the country have increased at the rate of over 240 per cent since the report of October 16th. It is of interest to note that a large part of these inquiries continue to come from technical schools and colleges, and thus it is evident that Engineering Council is having a part in the education of engineers. Among the more important subjects of inquiry are the engineering projects of foreign countries, the census of industries for 1919, reports of the Interstate Commerce Commission on plans to reorganize railroad districts, service orders and decisions of the Interstate Commerce Commission, the University Extension movement, reports of special investigations by the Geological Survey, and the work of the Board of Surveys and Maps.

Starting with the issue of December 7th, the weekly bulletin was again increased to two pages so as to record the increased number of items of interest to engineers, caused by the convening of Congress.

Board of Surveys and Maps

One of the interesting events in connection with the work of this Board was the presentation of a second report of the standing Committee on Coordination, the first report having been unsatisfactory and referred back to the committee for further consideration. The second report was obviously an effort on the part of certain members of the Board, whose desire is to prevent or postpone the coordination of mapping work, to set forth the reasons why the present mapping situation in the Government is not as bad as represented. The proposal that was made would leave the mapping operations in almost as bad a condition as existed prior to the efforts of Engineering Council. Your representative addressed a letter to the Chairman of the Board drawing his attention to this feature of the report and protesting against its acceptance. It appeared that his sentiments agreed with those of the majority of the Board, with the result that the report has again been referred back to its authors.

Prospective Legislation

(*a*) *Patents.* The Joint Conference Committee of the two houses on the Patent Office bill have announced the holding of hearings as soon as practicable after the holiday recess, the selected date to be announced sufficiently far in advance to enable the Patent Committee of the American Engineering Council to make its arrangements to appear.

(*b*) *Appropriations.* Your Washington representative has not taken part in any of the hearings before the sub-committees of the Appropriations Committee of the House of Representatives with respect to any of the items that have been favorably regarded by Council. He did, however, have a conference with the Chairman of the Appropriations Committee in which the latter set forth the necessity for severe economy. The point was made that it has now become a matter of good citizenship for all persons considerate of the public welfare to avoid urging any expansion in government operations. Your representative therefore thought that it would be well to place the matter again before Council and to ask whether, in the opinion of Council, it would not be well to avoid urging any increase in Government appropriations not absolutely necessary to the integrity of the Federal structure. There is one item of special interest to engineers which perhaps may constitute an exception to the above. It is that of adequate appropriation for the Federal Power Commission. At the last meeting of Council your representative announced that under a decision of the Comptroller, there is no money available except that for the salary of the Secretary, and in view of the importance of the matter Council approved the recommendation that efforts be made to assist in securing a suitable sum.

(*c*) *Engineers in the Public Health Service.* The bill drawn in the office of the Surgeon General to raise the rank of the engineering staff has not yet been officially submitted to Congress. It is understood that this bill will not involve more than a nominal increase of expenditure and therefore may properly be supported by the present Council if it appears in Congress prior to the suspension of its work.

Department of Public Works

The National Public Works Department Association will suspend on January 1st next for lack of funds, and the residue remaining in its treasury—between $400 and $600—will probably be paid over to the United Engineering Society for disbursement to the underwriter. What shall become of the association is a question now being discussed by the members of its Executive Committee, and it is desired to present to you certain considerations that are being discussed.

On December 14th the House of Representatives passed what is known as the Smoot-Reavis Joint Resolution providing for a joint committee of Congress to investigate the Government organization and from time to time to bring in legislative bills for reorganization. This marks the end of active efforts as to general propaganda for the establishment of a department of public works. Subsequent efforts, if exerted, would naturally

be to assist the committee of Congress and to convince it as to the necessity for a public works department. To establish such a conviction will probably not be difficult. The principle has received general acceptance and in the many discussions, both formal and informal, that the writer has heard on the subject in Congressional circles and elsewhere there has been no instance of divided opinion as to the necessity for a public works department.

It is believed by the writer that the adoption of the Smoot-Reavis Resolution, which is now an accomplished fact, will facilitate rather than delay final action on a public works department. The joint committee of Congress has the whole field of executive work to review, but it will naturally reach its conclusions first on those functions of Government for which the case has been prepared, and the public works functions are the only ones which have received any mature and detailed study.

The writer is advised that it is the intention of Council to suspend its work on December 31st. This report is therefore the last one which the writer will have the pleasure of making to this body. He is exceedingly grateful for the trust and confidence which Engineering Council has conferred upon him during the past two years. No member of Council is more mindful of his errors of judgment and of action than he is himself, and he therefore appreciates more than he can express the patience and forbearance that have been shown by members of Council, and his service for that body will always be remembered as one of the most pleasant and instructive experiences of his life.

Very respectfully,
(signed) M. O. Leighton.

PERSONAL MENTION

Julian Loebenstein, formerly connected with the firm of Viele, Blackwell & Buck, has been appointed chief engineer of the Hopewell Insulation & Manufacturing Company, Inc., Hopewell, Va.

E. E. Stark, formerly City Electrical Engineer, Christchurch, New Zealand, has returned to this country, and recently visited the Institute headquarters in New York. His present address is 409 Park Avenue. Elyria, Ohio.

Wm. S. Higbie, formerly electrical inspector with Guggenheim Bros., 120 Broadway, New York, has resigned his position with that firm and has organized an inspection and purchasing service with offices at 114 Liberty Street, New York.

J. L. McQuarrie, Assistant Chief Engineer of the Western Electric Co. laboratories, New York City, who has just returned from the Orient, was decorated by the Emperor of Japan before he sailed for home. He received the order of the Rising Sun, Fifth Class, in recognition of his services in the telephone engineering field and the aid he has rendered in the development of Japanese transmission progress.

Hugh A. Brown has been appointed sales manager of the Electro Dynamic Company. He will have his office at the Bayonne, N. J. works, and will have entire charge of the marketing of the products. Mr. Brown has had an extended experience in sales work, having been connected with a number of electrical concerns, among them the Crocker-Wheeler Company and Burke Electric Company.

Henry R. King, formerly power and light sales manager of the General Sales Department, Western Electric Company, has become general sales manager for the M. S. Wright Company, which supplies vacuum cleaners to the Western Electric Company. Mr. King is an expert on power apparatus and his work with the Western Electric Company for the past 22 years has been practically devoted to that branch of the business.

Edward W. Tree, for the past two years Associate Editor of *Mechanical Engineering*, the Journal of the American Society of Mechanical Engineers, has resigned from that position to become Associate Editor of *Management Engineering*, a new technical periodical to be published by The Ronald Press Company of New York. Mr. Tree was formerly instructor in Electrical Engineering at the Polytechnic Institute, Brooklyn, from which institution he was graduated in 1916 with the degree of Electrical Engineer.

Frederic M. Brown and T. D. Holihan announce the organization of the Brown-Holihan Sales & Engineering Corporation. The corporation has taken on the business of Mr. Brown, dealer in new and rebuilt electrical apparatus. Mr. Brown will continue his connection with this organization along with Mr. Holihan, who was with the Syracuse Lighting Company for nine years, during which time he handled central station and substation engineering, construction, operating and power sales. The corporation is located at 406-408 South Franklin Street, Syracuse, N. Y.

William Baum, consulting industrial engineer, Holeproof Hosiery Company, formerly in charge of the Operating Research Bureau of The Milwaukee Electric Railway & Light Company, will open a consulting practise in Chicago, Ill. on January 3rd 1921 as William Baum & Company, Industrial Engineers. The newly established consulting firm will specialize in the development of industrial management systems and the betterment of industrial relations. Prior to Mr. Baum's connection with the Milwaukee Railway & Light Company, he was Dean of the School of Engineering of Milwaukee for two years and for thirteen years electrical engineer and European representative of the General Electric Company, Schenectady, New York.

OBITUARY

Kenneth L. Scranton, of Rochester, N. Y., died on December 30, 1920. Born at Perry, N. Y., on July 29, 1887, Mr. Scranton received his technical education in Buffalo, and since 1903 had had experience with various electrical concerns. He became an Associate of the Institute in 1919.

William Robinson, of Brooklyn, N. Y., died in that city on January 2, 1921. Dr. Robinson was born November 22, 1840, in Ireland, of Scotch-Irish and English descent. His education was received at Wesleyan University and Boston University, with the degrees of A. M. and Ph. D., his course including Electrical and Mechanical Engineering. He was an inventor and patentee of much note, especially in automatic electric signaling for railroads. Outside of this line, one of his best known inventions was the Robinson radial car truck, which was used extensively on electric railways. He also turned his attention to turbine engines, making several improvements on these. Dr. Robinson joined the Institute in 1909, becoming a Fellow in 1913.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (From Dec. 1-31, 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

AIRCRAFT AND AUTOMOBILE MATERIALS OF CONSTRUCTION. Vol. 1. Ferrous Materials.

By Arthur W. Judge. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1920. 16+739 pp., illus., charts, tables, diagrams, 9x6 in., cloth, $9.00.

Contents: Stress, strain and elasticity.—The properties of materials under test.—Testing machines and methods.—The metallography of ferrous materials.—Irons and carbon steels. Alloy, or special steels.—Commercial forms of ferrous materials. The treatment of ferrous materials.—Heat treatment furnaces.—Pyrometry.—Metal joining processes.—The protection of metal surfaces.—Ferrous and other alloys.

This book has been written for the use of the ferrous materials employed in the construction of automobiles and aircraft and in general mechanical construction. It therefore is not concerned with the metallurgical processes to which these materials may have been previously subjected, but with their composition, strength and properties as received from the steel manufacturer and with modes of heat and other treatment. The work covers a wide range, and is intended as a reference work for designers and builders of machines.

AMERICAN RURAL HIGHWAYS.

By T. R. Agg. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 11+139 pp., front., illus., 8 x 5 in., cloth, $2.00.

This textbook was written for use in courses on rural highways given to agricultural engineers, students of agriculture and others who do not receive training along the lines of the usual course in highway engineering. It is intended to familiarize the student with the relation of highway improvement to national progress, to indicate the problems of highway administration and to set forth the usual methods of design and construction in sufficient detail to establish a clear understanding of the characteristics and serviceability of the common types of roadway surface.

APPLICATION OF DYESTUFFS TO TEXTILES, PAPER, LEATHER AND OTHER MATERIALS.

By J. Merritt Matthews. N. Y. John Wiley & Sons, Inc., Lond., Chapman & Hall, Ltd., 1920. 16+768 pp., illus., tables, 9 x6 in., cloth, $10.00.

The present volume is an outgrowth of the author's earlier work, "Laboratory Manual of Dyeing and Textile Chemistry," but has been broadened in scope to appeal to the interest, not only of students, but of all those concerned in the application of dyestuffs. The author has endeavored to incorporate the latest knowledge of the subject. Contains an eighteen-page bibliography.

THE CERAMIC INDUSTRIES POCKET BOOK.

By Alfred B. Searle. Lond. and N. Y., Sir Isaac Pitman & Sons., Ltd., 1920. 7+267 pp., diagrams, tables, 6 x 4 in., cloth, $3.40.

Of actual pocket size, this little volume is a compilation of data that have been found of constant use to people engaged in the clay-working, glass and allied industries.

COMPRESSED AIR PLANT; THE PRODUCTION, TRANSMISSION AND USE OF COMPRESSED AIR, WITH SPECIAL REFERENCE TO MINE SERVICE.

By Robert Peele. Fourth edition, revised and enlarged. N. Y., John Wiley & Sons, Inc., Lond., Chapman & Hall, Ltd., 1920. 23+506 pp., illus., diagrams, tables, 9 x 6 in., cloth $4.50.

This volume deals with the varied uses of compressed air in engineering, particularly in mining, tunneling, quarrying and other work involving rock excavation. A chapter on the measurement of air consumption has been added to this edition, and also information on air-lift work. Typographical errors have also been corrected.

THE COST OF MINING.

By James Ralph Finlay. Third edition, revised, enlarged and reset. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 11+532 pp., maps, tables, 9 x 6 in., cloth. $6.00.

This work was originally a study of the cost of mining the more important economic minerals, undertaken to show how the natural factors invariably impose certain costs that sound engineering must recognize, and that to attempt economies unjustified by the conditions is extravagance.

The present edition has been broadened in scope, chiefly by the insertion of generalizations on geologic history and processes that tend to explain the origin and govern the distribution of important minerals. It is less narrowly technical than its predecessors and pays more attention to those aspects of mining economics which interest the public generally.

DETAIL DESIGN OF MARINE SCREW PROPELLERS.

By Douglas H. Jackson. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1920. 12+92 pp., tables charts, diagrams, 9 x 6 in., cloth, $2.50.

The author feels that many works on screw-propeller design carry theoretical considerations too far for the average designer. He therefore here presents, in small compass, an outline of the accepted theories, a full treatment of the practical application of them, and a short description of the various manufacturing methods. A chapter on repair work is also included.

THE DEVELOPMENT OF INSTITUTIONS UNDER IRRIGATION, WITH SPECIAL REFERENCE TO EARLY UTAH CONDITIONS.

By George Thomas, N. Y., The Macmillan Co., 1920. 7+293 pp., front., plate, 8 x 5 in., cloth, $2.50.

Irrigation on a large scale was first practised in America by the Utah pioneers. The present book is an account of the methods that they adopted to solve successfully one phase of the problem of irrigation, the institutional one. How the expenses of irrigation works were met, and the distribution and use of water controlled, are concisely related. The history is brought down to 1919.

A DICTIONARY OF CHEMICAL TERMS.

By James F. Couch. N. Y., D. Van Nostrand Co., 1920. 4+204 pp., 7 x 5 in., cloth $2.50.

This volume is designed to serve the convenience of readers of chemical literature by providing accurate definitions for the complex terminology of this science, in convenient form. The

treatment of the terms lies between that of a standard dictionary of the English language and that of an encyclopedia.

ELECTRO-DEPOSITION OF METALS.

By George Langbein. Translated, with additions, by W. T. Brannt. Eighth edition, revised and enlarged. N. Y., H. C. Baird & Co., Inc., 1920. 12+863 pp., illus., diagrams, 9 x 6 in., cloth, $7.50.

This book is intended as a reference book and practical guide on electroplating, based upon the scientific principles underlying the art, but devoid of mathematical technicalities. The present edition has been thoroughly revised and modernized and new methods have been added wherever necessary.

ENCYCLOPEDIA OF MARINE APPLIANCES, 1920.

Compiled by Alexander McNab. Bridgeport, Conn., The McNab Company. 206 pp., illus., 12 x 9 in., cloth. $5.00.

An interesting catalog of marine appliances, made or sold by the publishers.

THE ENGINEERING DRAUGHTSMAN.

By E. Rowarth. N. Y., E. P. Dutton and Company. 24+245 pp., diagrams, tables, 9 x 6 in., cloth. $5.00.

This book, intended for those familiar with the elementary principles of engineering drawing, is a collection of ninety-six exercises arranged to illustrate the application of the principles in the production of working drawings. These examples show how working drawings of details are made from information obtained from general assembly drawings, how assembly drawings are made from detailed working drawings, how detailed working drawings are modified in shape and size, to suit new machines. The plates cover a wide range of work and are taken from drawings of commercial machines.

THE ESSENTIALS OF DESCRIPTIVE GEOMETRY.

By F. G. Higbee. Third edition, revised. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1920. 8+218 pp., diagrams, 9 x 6 in., cloth. $2.25.

In writing this text the author has endeavored to include only those portions of descriptive geometry which possess industrial utility and assist in the development of a draftsman. The present edition is like the original in essentials, but certain changes have been made, in the light of classroom experience, in order to make the book more clear to the student.

HANDBOOK OF BUILDING CONSTRUCTION

Editors-in-chief, George A. Hool and Nathan C. Johnson. First edition, first impression. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 2 vols., front., illus., diagrams, tables, 9 x 6 in., cloth, $10.00.

This has been prepared to provide the architect, engineer and builder with a reference work covering thoroughly the design and construction of the principal kinds and types of modern buildings, and their mechanical and electrical equipment. Each section is the work of a specialist, and although condensed gives the information usually needed for reference by the engineer in practise. The volumes are fully illustrated by diagrams and figures.

HIGH FREQUENCY APPARATUS; DESIGN, CONSTRUCTION AND PRACTICAL APPLICATION.

By Thomas Stanley Curtis. Second edition, revised and enlarged. N. Y., Norman W. Henley Publishing Co., 1920. 269 pp., illus.. diagrams, 8 x 5 in., cloth, $3.00.

This book is a practical non-technical text-book, intended particularly for amateurs and other experimenters, and is based on a series of papers which appeared in various popular technical magazines. This edition has been slightly enlarged.

HIGHER MECHANICS.

By Horace Lamb. Cambridge, University Press, 1920. 10+272 pp., front., diagrams, 9 x 6 in., cloth. $8.00. (Gift of the Macmillan Company).

This treatise includes three-dimensional kinematics, statics and dynamics, and may be regarded as a sequel to the author's two former treatises on statics and dynamics. The author attempts to confine his attention to matters of genuine kinematical or dynamical importance, and to avoid those of purely mathematical or historical interest. The book is designed as an introduction to the subject.

THE HUMAN MOTOR OR THE SCIENTIFIC FOUNDATION OF LABOR AND INDUSTRY.

By Jules Amar. Lond., George Routledge & Sons, Ltd., N. Y., E. P. Dutton & Co., 1920. 15+470 pp., illus, charts, diagrams, 9 x 6 in., cloth. $10.00. (Gift of E. P. Dutton & Company).

This book is a study of the human body as a motor and of the conditions that govern its effectiveness. The author has collected the physiological data which govern the efficiency of human work and has also included a brief summary of the principles of mechanics. The work of Chauveau and Taylor is discussed and criticized, and the latter's system carefully examined.

LEAD, INCLUDING LEAD PIGMENTS AND THE DESILVERISATION OF LEAD.

By J. A. Smythe. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1920. (Pitman's common commodities and industries) 7+120 pp., front., illus., map, 7 x 5 in., cloth, $1.00.

This is a brief, straightforward account, free from technicalities, of the various processes used from the time the lead ore is dug out of the earth until the pure metal and the pigments derived from it are put on the market. No previous knowledge of chemistry and physics is required by the reader.

THE LIFE AND WORK OF SIR WILLIAM VAN HORNE.

By Walter Vaughan. N. Y., The Century Company, 1920. 13+388 pp., ports., plates, 9 x 6 in., cloth, $5.00.

Sir William Van Horne's great achievement was the construction of the Canadian Pacific and its development into a great railroad system. To the story of this achievement the greater part of Mr. Vaughan's book is devoted, but he has also treated adequately Sir William's earlier experience in railroad operation in the United States and the various projects which occupied his later life after his retirement from the presidency of the Canadian Pacific. His personality is adequately and sincerely treated, so that the book is a human record of the man, as well as a history of a railroad.

THE MODERN ELECTROPLATER.

By Kenneth M. Coggeshall. N. Y., The Norman W. Henley Publishing Co., 1920. 276 pp., illus. charts, diagrams, tables, 8 x 5 in., $3.00.

This volume is practical in purpose. It contains a description, presented as simply as possible, of the equipment and methods for electroplating in use today.

MODERN EXPLOSIVES.

By S. I. Levy. London and N. Y., Sir Isaac Pitman & Son, Ltd., 1920. (Pitman's common commodities and industries). 9+109 pp., front., illus., 7 x 5 in., cloth, $1.00.

Upon the basis of experience gained during the war, the author of this little book gives an account for general readers of the modern explosive industry. Stress is laid on the interdependence of modern industry and the necessity of viewing all research and productive activity as a whole not only for the purpose of defense, but to insure the well-being of the community.

PAPERS ON PAINT AND VARNISH AND THE MATERIALS USED IN THEIR MANUFACTURE.

By Henry A. Gardner. Washington, D. C., 1920. 501 pp., front., ports., illus., diagrams, tables, 9 x 6 in., cloth, $10.00. (Gift of the author).

In this volume the author brings up to date the series of technical papers which he has prepared as circulars of the Educational Bureau of paint and Varnish Manufacturers Association, since January 1919. The papers cover a wide variety of practical subjects, and are intended to bring a fuller realization of the importance of surface protection and a better understanding of how to obtain and maintain it.

POLITICAL AND COMMERCIAL GEOLOGY AND THE WORLD'S MINERAL RESOURCES; a Series of Studies by Specialists.

J. E. Spurr, editor. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 9+562 pp., diagrams, tables, 9 x 6 in., cloth, $5.00.

The purpose of these studies is to shed light upon the vast importance of commercial control of raw materials by different powers, or by citizens of those powers, through invested capital. The question of domestic and foreign governmental policies

of the United States is closely involved. This volume takes up the study of the actual situation as to the distribution and ownership of mineral supplies in the world and forms almost the first contribution to the investigation of the relation of geology to industry, commerce and political economy.

THE PRACTISE OF RAILWAY SURVEYING AND PERMANENT WAY WORK.

By S. Wright Perrot and F. E. G. Badger. London, Edwin Arnold, 303 pp., diagrams, charts, tables, 9 x 6 in., cloth, $10.50. (Gift of Longmans, Green and Company).

The object aimed at is to deal with the practical side of the subject, a knowledge of surveying in general being assumed. The authors gained their experience as members of the staffs of two leading English railways and also when carrying out railway work abroad. The knowledge thus acquired of the best English practise, as well as of the methods adopted in the construction of economic railways in unexplored and undeveloped countries, has enabled them to deal with the subject from the practical point of view. Many methods are original. Little or none of the matter on permanent way has previously appeared in print.

P-W-R MANUAL.

Phila., Power-Weightman-Rosengarten Co., 1920. 7+471 pp., tables, 8 x 5 in., cloth.

This is a dictionary of chemical and pharmaceutical products, giving the formulas, percentage compositions and properties of each. A collection of tables useful to analysts and others is appended.

RAPID METHODS FOR THE CHEMICAL ANALYSIS OF SPECIAL STEELS, STEEL-MAKING ALLOYS, THEIR ORES AND GRAPHITE.

By Charles Morris Johnson. Third edition, revised and enlarged. N. Y., John Wiley & Sons, Inc., Lond., Chapman-Hall Ltd., 1920. 11+552 pp., illus., tables, 9 x 6 in., cloth, $6.00.

This collection of analytical methods, by the chief of a large steel-works laboratory, represents the results of long experience in the rapid examination of steel-works materials. Many methods are original. The present edition has been expanded to include a considerable number of new methods which have been developed since the last revision of the book.

THE STANDARD ELECTRICAL DICTIONARY.

By T. O'Conor Sloane. With additions by A. E. Watson. N. Y., The Norman W. Henley Publishing Co., 1920. 767 pp., illus., diagrams, 7 x 5 in., cloth, $5.00.

Since its appearance in 1892, this work has passed through many editions and found favor as an encyclopedia dictionary of the subject. The present edition has been revised and enlarged by the addition of a second part, 185 pages long, containing the terms, appliances and theories of modern times. Cuts and diagrams are used to elucidate the text.

STORAGE BATTERY MANUAL.

By Lucius C. Dunn. Annapolis, U. S. Naval Institute, 1920. 391 pp., illus., diagrams, 9 x 6 in., cloth, $7.00.

The book is the work of a Lieutenant Commander, U. S. Navy, and is designed for the instruction of the personnel of the navy. The text has been made as simple and practical as possible, and involved formulas and mathematical expressions have been avoided wherever possible.

STORAGE BATTERY PRACTISE.

By Robert Rankin. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 11+169 pp., diagrams, charts, 9 x 6 in., cloth, $3.10.

This is an attempt to present, in concise, readable form, an account of the manufacture, installation, properties and working of storage batteries, for the practical engineer, who is not so much concerned with the details of manufacture and theory, as with the operation and maintenance of storage batteries and the auxiliary plant. The book deals mainly with stationary batteries.

THE STORY OF THE ENGINE, FROM LEVER TO LIBERTY MOTOR.

By Wilbur F. Decker. N. Y., Charles Scribner's Sons, 1920. 20+277 pp., front., illus., 8 x 5 in., cloth, $2.50.

This book is intended for readers without any previous knowledge of the subject. Beginning with the lever, the first elementary mechanical movement, the author traces the applications of mechanical principles, the gradual development of the steam engine in its various forms, and the internal combustion engine. Numerous diagrams assist the text.

TEXT-BOOK OF THE MATERIALS OF ENGINEERING.

By Herbert T. Moore. With a chapter on concrete, by H. F. Gonnerman. Second edition, first impression. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 12+315 pp., illus., charts, tables, 9 x 6 in., cloth, $3.00.

This textbook contains a concise presentation of the physical properties of the common materials used in structures and machines, together with brief descriptions of their manufacture and fabrication. It is primarily intended for use in connection with courses on the mechanics of materials, but the author hopes that it will also be useful to draftsmen, inspectors, machinists and others who use these materials.

In this edition the chapter on concrete has been rewritten, a chapter on rubber, leather and hemp rope, and other sections have been enlarged or revised.

THEORETICAL ORGANIC CHEMISTRY.

By Julius B. Cohen. Lond. Macmillan and Co., Ltd., 1920. 15+604 pp., illus., diagrams, 7 x 5 in., cloth, $2.50.

In preparing a new textbook on this subject, the author's chief aim has been to maintain a careful balance between theory and practise. The book represents the author's lectures to his students, is equipped with class demonstrations, and endeavors to arouse the curiosity and interest of the student.

THE THERMIONIC VACUUM TUBE, AND ITS APPLICATIONS.

By H. J. Van der Bijl. First edition, N. Y., and Lond., McGraw-Hill Book Co., Inc., 1920. 19+391 pp., illus., charts, diagrams, 9 x 6 in., cloth, $5.00.

In this work the author has attempted to set forth the principles of operation of these tubes and to coordinate the more important phenomena exhibited by the passage of electrons through high vacua. The treatment has been made elementary enough for those unacquainted with the subject.

THE VENTILATION HAND BOOK.

By Charles L. Hibbard. Second edition, revised and enlarged. N. Y., The Sheet Metal Publication Co., 1920. 231 pp. illus., diagrams, 8 x 6 in., cloth, $2.50.

This book is intended to present, in convenient form, the principles of warm-air heating and ventilation, with simple methods for computing the sizes of the various parts of a system of this kind. The subject matter is arranged in the form of questions and answers, and the descriptions and mathematical data are given in very simple form.

WIRTSCHAFTLICHE VERWERTUNG DER BRENNSTOFFE.

By G. de Grahl. Zweite, neu bearbeitete auflage. Munchen and Berlin, R. Oldenburg, 1921. 8+487 pp., plates, illus., charts, diagrams, 11 x 8 in., paper M.110.

This work on the economical utilization of fuels first appeared in 1915, when the economic isolation of Germany began to be effective. The present edition has been entirely rewritten in the light of the fuel situation after the war, and is an exhaustive treatise on the utilization of the available fuel supply under present conditions.

After a description of the solid, gaseous and liquid fuels, in which their efficiencies are compared, the author discusses the processes for converting and enriching them. Gas production, by-products, nitrogen utilization are treated in detail. The subject of combustion is then taken up and an extended critical discussion of methods of firing especially for steam production, is included. Another chapter discusses heating for municipalities, waste heat utilization, etc. The concluding chapter treats of the economics of energy in general. Because of its comprehensiveness, the book will interest many engineers.

WATER PURIFICATION PLANTS AND THEIR OPERATION.

By Milton F. Stein. Second edition. N. Y. John Wiley & Sons, Inc., Lond., Chapman-Hall Ltd., 1919. 10+270 pp., illus., charts, diagrams, 9 x 6 in., cloth, $3.00.

The object of the author has been to give instruction for the operation of these plants, as concisely and simply as is consistent with reasonable completeness. In general, it has been the endeavor to give special attention to the requirements of the non-technical operator of small plants. This edition has been rewritten in part, because of changes in the technique of water bacteriology, new views as to the interpretation of bacteriological tests and the need for new details in the instruction for these tests.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Akron.—November 24, 1920. Paper: "Motors in Rubber Industry." Author: Mr. M. Berthold. Chief Engineer, Imperial Electric Company, Akron, Ohio. Attendance 23.

December 22, 1920. Paper: "Recent Developments in Transformer Application and Design." Author: Mr. L. E. Wright, General Electric Company, Cincinnati, Ohio. Attendance 23.

Baltimore.—December 17, 1920, Johns Hopkins University. Business meeting followed by illustrated lecture on "Alternating-Current Motors Having Series and Shunt Characteristics" by Mr. R. A. Jones, of the General Electric Company. Attendance 70.

Boston.—December 17, 1920, Chipman Hall, Tremont Temple. Joint meeting of Boston Sections of A. I. E. E. and A. S. M. E., and the Boston Society of Civil Engineers. Subject: "Water Power Development in New England." Speaker: Professor Harold K. Barrows; discussion by Mr. Henry I. Harriman, President of the New England Power Company, who talked particularly upon the St. Lawrence project. Attendance 350.

Chicago.—December 17, 1920. Papers: "Automatic Railway Substations" by Mr. Charles H. Jones, of the Chicago, North Shore & Milwaukee R. R.; "Economic Aspects of the Light Weight Safety Car" by Mr. H. A. Johnson, Chicago, North Shore & Milwaukee R. R., and Mr. H. L. Brown, Western Editor for *Electric Railway Journal*; "Train Operation on Urban Railways" by Mr. S. B. Way, of The Milwaukee Electric Railway & Light Company. Attendance 200.

Cincinnati.—December 21, 1920, Dayton Engineers Club, Dayton, O. Subject: "Insulation Research, a Review and a Forecast." Speaker: Mr. C. E. Skinner, of the Westinghouse Elec. & Mfg. Co. Attendance 60.

Cleveland.—December 21, 1920, Cleveland Engineering Society Club Rooms. Subject: "The Purchase and Use of Electric Motors from the Owners' Standpoint." Speaker: Mr. James Burke, of the Burke Electric Company. Attendance 92.

Denver.—December 11, 1920. In the afternoon an automobile trip was made to the Brighton Plant of the Great Western Sugar Company. The party, consisting of about fifty, was taken in charge by members of the sugar company's organization and the production of beet sugar was explained from the unloading of the beets to the sacking and storing of the sugar. This was followed by a dinner at the Metropole Hotel, where Mr. B. Hutchins, Traveling Superintendent for the Great Western Sugar Company, gave a talk on sugar.

Fort Wayne.—December 16, 1920, University Club. Subject: "Evolution of the Fort Wayne Electric Works." Speaker: Mr. J. J. Kline, of the General Electric Company. Refreshments were served. Attendance 37.

Indianapolis-Lafayette.—December 17, 1920. Chamber of Commerce. Subject: "Light and Lenses." Speaker: Mr. L. W. Bugbee, of the One-Piece Bi-Focal Lens Company, of Indianapolis. Refreshments were served. Attendance 36.

Ithaca.—December 3, 1920, Franklin Hall, Cornell University. Subject: "Electric Furnaces for Steel Production." Speaker: Mr. E. T. Moore. Attendance 135.

Los Angeles.—December 7, 1920, Chamber of Commerce. Illustrated talk on "The What and Why of Industrial Illumination." Speaker: Mr. O. L. Johnson, of the Benjamin Electric Mfg. Co. Attendance 80.

Lynn.—December 8, 1920, G. E. Hall. Subject: "Super-Power System." Speaker: Mr. W. S. Murray. Attendance 250.

December 20, 1920, G. E. Hall. Subject: "The Fundamentals of Our Economic System." Speaker: Professor Ralph E. Heilman, Dean of the Northwestern University School of Commerce, Chicago. Attendance 245.

Madison.—December 14, 1920, Engineering Building, Univ. of Wis. Paper: "Resistance Neutralization: An Application of Thermionic Amplifier Circuits" (prepared jointly by Professor Edward Bennett and Mr. L. J. Peters, of the University of Wisconsin) presented by Mr. Peters. Attendance 30.

Philadelphia.—December 13, 1920, The Bellevue Stratford Hotel. Informal dinner. Subject: "Super-Power System." Speaker: Mr. William S. Murray. Attendance 558.

Pittsburgh.—December 14, 1920, Chamber of Commerce. Subject: "A Transition Period in Radio Communication." Speaker: Mr. Arthur F. Van Dyck, of the Radio Corporation of America. Attendance 200.

Pittsfield. December 2, Masonic Temple. Subject: "The Foremost Civilization of America." Speaker: Mr. Sylvanus G. Morley, Carnegie Institute. Attendance 400.

December 16, 1920, Boys' Club. Subject: "Some Ice Problems and Their Solutions." Speaker: Mr. John Murphy, Electrical Engineer of the Department of Railway and Canals, Canadian Government. Attendance 250.

January 6, 1921, Park Club. Subject: "Industrial Reconstruction in France and Belgium." Speaker: Major O. F. Allen. Attendance 230.

Portland.—December 14, 1920, University Club. Papers presented, "Contracting" by R. C. Kenney; "Accounting" by Mr. McCoy; "Fixtures" by J. C. English; "Merchandising" by C. P. Scott. Meeting was held under the auspices of the Contractors-Dealers Association. Attendance 100.

St. Louis.—December 17, 1920, American Annex Hotel. Election of officers as follows: Chairman, Mr. J. L. Woodress; Secretary-Treasurer, Mr. Walter H. Millan. Paper presented: "Automatic Substations." Speaker: Mr. R. J. Wensley, of the Westinghouse Company. Attendance 109.

San Francisco.—December 17, 1920, Engineers Club. Paper: "Electric Design and Utilization in Pacific Coast Industries." Speaker: Mr. L. F. Leurey. Attendance 45.

Schenectady.—December 17, 1920, Edison Club Hall. Subject: "Industrial Reconstruction in France and Belgium." Speaker: Major O. F. Allen. Attendance 250.

January 7, 1921, Edison Club Hall. Subject: "The Manufacture and Use of Die Castings." Speaker: Mr. Chas. Pack, Chief Chemist Doehler Die Casting Company of Brooklyn, N. Y. Attendance 175.

Seattle.—December 21, 1920, Arctic Club Assembly. Business meeting, followed by discussion of Mr. Ross' paper as presented at the November meeting. Attendance 65.

Spokane.—December 18, 1920, Davenport Hotel. Subject: "Wireless Telegraphy and Telephony." Speaker: Mr. E. V. Olson, of the Washington Water Power Co. Attendance 98.

Syracuse.—December 10, 1920, Technology Club. Subject: "Where Syracuse Gets Power." Speaker: Mr. W. C. Pearce. Attendance 72.

Toronto.—December 10, 1920, University of Toronto. Paper: "Submarine Detection in an Alternating Magnetic Field." Author: Dr. John B. Whitehead, John Hopkins University. Attendance 83.

December 22, 1920, University of Toronto. Joint meeting of the Toronto Section of the A. I. E. E. and The Royal Canadian Institute. Subject: "The Twentieth Century's Contribution to our Knowledge of the Atom." Speaker: Dr. R. A. Millikan, of the University of Chicago. Attendance 416.

Urbana.—December 17, 1920. Subjects: "Opportunities with the Westinghouse Company" by Mr. P. A. Burkhardt; "Recent Developments in Radio Engineering" by Mr. H. A. Brown. Attendance 60.

Utah.—December 11, 1920, Commercial Club. Paper: "Habits of the Electron" (illustrated with slides). Author: Dr. Saul Dushman. Attendance 65.

Washington.—December 14, 1920, Cosmos Club Hall. Mr. R. E. Wooley, Manager of the Flow Meter Department of the G. E. Co., delivered an illustrated address on the description and principles of flow meters of various makes, the use of these instruments on boilers and in steam lines for industrial purposes, heating, etc. Refreshments were served. Attendance 124.

Worcester.—January 4, 1921, Worcester Polytechnic Institute. Subject: "Power Transmission." Speaker: Mr. E. W. Pragst, Power and Mining Department, General Electric Company. Attendance 103.

PAST BRANCH MEETINGS

Brooklyn Polytechnic Institute.—December 9, 1920. Subject: "History and Development of the Telephone." Speaker: Mr. Howard W. Mott, of the Western Electric Company. Attendance 30.

Carnegie Institute of Technology.—December 7, 1920. Subjects: "Merchandising of Electrical Equipment" by Mr. Clarke, Sales Dept., Westinghouse Elec. & Mfg. Co. "Publicity and Trade Promotion" by Mr. Waxman, Sales Dept., Westinghouse Elec. & Mfg. Co. Attendance 31.

Case School of Applied Science.—December 14, 1920. A talk was given by Mr. C. C. Dash, of the Hertner Electric Company, Cleveland, on the Application of Motor Generator Sets to Motion Picture Projection. Attendance 41.

University of Cincinnati.—November 23, 1920. Illustrated talk on "Some Special Features of the New Dixie Terminal Buildings of Cincinnati" by Mr. C. F. Fosdick, engineer with Walter Frantz. Attendance 92.

November 30, 1920. Subject: "Public Utilization and the Growth of the Power Company in Cincinnati." Speaker: Mr. W. W. Freeman, President of the Union Gas & Elec. Co. of Cincinnati. Attendance 68.

December 7, 1920. Mr. C. F. Fosdick repeated his talk of November 23, on "Some Special Features of the New Dixie Terminal Buildings of Cincinnati." Attendance 50.

Clemson College.—January 11, 1921. Debate: "Steam Locomotives versus Electric Locomotives." Steam—Messrs. Hoffmeyer and Tyler; Electric—Messrs. Watkins and Readen. Debate was won by the advocates of the steam locomotive. Current events were given by H. W. Hood. Attendance 42.

University of Colorado.—December 2, 1920. Talk by Mr. R. Prout, of the Western Union Telegraph Co. of Denver, on "Multiplex Telegraph System." Attendance 38.

University of Iowa.—December 6, 1920. Subjects: "Air Craft Radio" by M. Carlson, and "The New Niagara Power Project" by H. E. Hood. Attendance 31.

December 13, 1920. Subjects: "The Incandescent Lamp" by R. Klatt, and "Thawing of Water Pipes by Electricity" by A. P. Byers. Attendance 34.

University of Kansas.—December 12, 1920, Fraser Hall. The following moving pictures were shown: "The Benefactor," "The Electric Giant," "The Potters Wheel," and "The Land of Cotton." Attendance 50.

University of Kentucky.—December 13, 1920, Mechanical Hall. Subjects: "Oscillators on Electrical Machinery" (taken from Power) by E. O. Shultz, and "Lightning Arresters" by B. Thornton. Attendance 22.

University of Maine.—December 8, 1920, Lord Hall. Mr. W. A. Taylor talked of his work during the summer with the General Electric Company, and Mr. W. J. Creamer outlined his work with the Western Electric Company during the war on the development of the "sea-phone" used for detection of submarines. Attendance 22.

Massachusetts Institute of Technology. January 12, 1921. Subject: "The Story of the Telephone." Speaker: Mr. W. H. Freedman, of the A. T. & T. Co., New York. Refreshments were served. Attendance 92.

University of Minnesota.—December 20, 1920. Subjects: "The Signal Corps in The World War" by Major Ingles; "The Joint Engineering Board" by Professor G. D. Shepardson. Attendance 37.

University of Notre Dame.—December 6, 1920. Election of officers as follows: Chairman, Frank Miles; Vice-Chairman, D. Fitzgerald; Secretary, W. Shiltz; Treasurer, J. Huether. Attendance 21.

December 17, 1920. Subject: "What is Electricity?" Speaker: Dean Fitzgerald. Attendance 16.

Ohio Northern University.—December 20, 1920. Subjects: "The Colfax Power Station" by Howard D. Ronk; "The 150,000-Volt Transmission Line of the Knoxville Power Co." by F. W. Beyer (this article taken from JOURNAL, by Theodore Varney). Attendance 13.

Ohio State University.—December 16, 1920. Business meeting, followed by a social period and talk by Y. T. Yang, a Senior from China, on "The Achievements of Engineering in China." Attendance 25.

University of Oklahoma.—December 9, 1920. Moving picture "The King of the Rails" was shown. Attendance 163.

Oregon State Agricultural College.—December 15, 1920. Moving picture "The Land of Cotton" was shown. Attendance 15.

University of Pennsylvania.—December 7, 1920. Subject: "Lighting of Buildings." Speaker: Mr. D. Albertson. Attendance 48.

December 14, 1920. Subject "Telephone Cables." Speaker Mr. G. C. Eldridge. Attendance 48.

January 4, 1920. Subject: "Power Requirements of Telephone Central Offices." Speaker: Mr. J. F. Haines. Attendance 48.

Purdue University.—December 14, 1920. Joint meeting of the Purdue Branches of A. I. E. E., A. S. M. E. and Civil Engineering Society. Subject: "Design, Construction and Operation of Water Turbines." Speaker: Mr. D. J. McCormack, Hydraulic Engineer for the Wellman, Seaver, Morgan Co. Attendance 189.

Rose Polytechnic Institute.—December 15, 1920. Subject: "Electric Arc Welding Processes and Application." Speaker: Mr. W. W. Reddie, of the Westinghouse Elec. & Mfg. Co. Attendance 163.

University of Texas.—January 10, 1921. Talks by Messrs. Bantel and Bryant. Moving picture "The Benefactor" was shown. Attendance 310.

University of Virginia.—December 2, 1920. Demonstrated lecture on "Audion Bulbs" by Professor L. G. Hoxton. Attendance 40.

University of Washington.—December 7, 1920. Mr. A. Kalin, a member of the E. E. faculty, gave a talk on the school of instruction of the Westinghouse Company with whom he has been for the last year. Attendance 28.

Washington State College.—December 10, 1920. Subject: "The Successful Man." Speaker: Professor M. K. Synder. Attendance 22.

West Virginia University.—December 13, 1920. The following papers were read: "Electric Safety Lamps," by H. S. Shinn; "Suspension Insulators," by H. Chandler; "Mercury Vapor Lamps," by A. C. Price; "Measurement of Projectile Velocities," by J. L. Hark; "Advantages of Electric Drive for Battleships," by C. M. Hill. Attendance 13.

January 10, 1921. The following papers were read: "Wireless Telephony," by R. D. Brown; "Factory Lighting," by H. Chandler; "Some A. I. E. E. Meetings I have Attended," by H. M. McLain. Attendance 14.

Yale University.—December 14, 1920. Subject: "Joint Use of Overhead Lines—Telephone and Power." Speaker: Mr. T. N. Bradshaw, Outside Engineer of Southern New England Telephone Company. Attendance 49.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

To assist in the conduct of engineering research and to extend and strengthen the field of its graduate work in engineering, the University of Illinois maintains fourteen Research Graduate Assistantships in the Engineering Experiment Station. Two other such assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $600 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools who are prepared to undertake graduate study in engineering, physics, or applied chemistry.

An appointment to the position of Research Graduate Assistant is made and must be accepted for two consecutive collegiate years, at the expiration of which period, if all requirements have been met, the degree of Master of Science will be conferred. Not more than half of the time of a Research Graduate Assistant is required in connection with the work of the department to which he is assigned, the remainder being available for graduate study.

Nominations to these positions, accompanied by assignments to special departments of the Engineering Experiment Station, are made from applications received by the Director of the Station each year not later than the first day of March. The nominations are made by the Executive Staff of the Station, subject to the approval of the President of the University. Nominations are based upon the character, scholastic attainments, and promise of success in the principal line of study or research to which the candidate proposes to devote himself. Preference is given those applicants who have had some practical engineering experience following the completion of their undergraduate work. Appointments are made in the spring, and they become effective the first day of the following September. Vacancies may be filled by similar nominations and appointments at other times.

The Engineering Experiment Station, an organization within the College of Engineering, was established in 1903 for the purpose of conducting investigations in the various branches of engineering, and for the study of problems of importance to engineers and to the manufacturing and industrial interests of the State of Illinois. Research work and graduate study may be undertaken in architecture, architectural engineering, ceramic engineering, chemistry, civil engineering, electrical engineering, mechanical engineering, mining engineering, municipal and sanitary engineering, physics, railway engineering, and theoretical and applied mechanics.

The work of the Engineering Experiment Station is closely related to that of the College of Engineering, and the Heads of Departments in the College constitute the Executive Staff of the Station. Investigations are carried on by members of the Station staff and also by members of the instructional staff of the College of Engineering.

Additional information may be obtained by addressing

THE DIRECTOR,
Engineering Experiment Station,
University of Illinois,
Urbana, Illinois.

SEVERAL RECENT TECHNICAL GRADUATES wanted by central station in East. Applicants to start in various departments of the Company and will be promoted as they gain experience. Give education, any experience and salary expected at start. Z-2643.

YOUNG MAN WITH TECHNICAL EDUCATION and experience in the design, construction and operation of 2200 volt or standard city distribution lines. Reply giving education, experience, references and salary expected. Z-2644.

SALES ENGINEER. Must be a technical graduate with E. E. degree. between 22-35 years old. Some sales, testing and, repairing experience in small motors desirable. Location New York City. Z-2648.

ELECTRICAL DRAFTSMAN. Experienced in substation design, conduit and switchboard layout. State age, experience, education and salary expected. Location Wisconsin. X-19.

ASSISTANT PHYSICIST for research work with government. X-60.

YOUNG ELECTRICAL ENGINEER with some experience in development, teaching, test, radio or laboratory, as Junior in development laboratory for automotive equipment. Unusual opportunity for a man of good fundamental training and proper personal qualifications. Location Mass. X-46.

YOUNG MAN, age 25; married; partial technical training. Five years electrical experience on actual construction, engineering and drafting, designing of power plants and substations, switchboards and general electrical installations. Desires position with prospects for advancement. Location Philadelphia or near by. Available immediately. E-2491.

ELECTRICAL ENGINEER, available immediately for purchasing, sales or responsible engineering position. Six years broad electrical experience. G. E. test, development work, public utility, maintenance, refrigeration; 1½ years export; excellent grasp of mechanical engineering. Degree E. E., Columbia. Age 29, married. Associate A. I. E. E. Willing to travel. Energetic, capable, good personality. Best references. E-2492.

COMBUSTION ENGINEER, desires connection with fuel burning power plant. Has available methods of reducing fuel costs by one dollar per ton, and also of substantially increasing boiler ratings. E-2493.

ELECTRICAL MECHANICAL ENGINEER, A. I. E. E., age 42; married, university graduate. Fifteen years experience in design and construction of power and substations, electrical machinery and equipment, and industrial engineering. Thoroughly conversant with a. c. and d. c. systems and distribution, high and low tension in U. S. A. and abroad. E-2494.

PHYSICIST ELECTRICAL ENGINEER, age 31; married. Member A. I. E. E. and American Physical Society. College graduate. Practical, executive and teaching experience in electrical engineering and physics. Available on reasonable notice. Can give references and particulars to those interested. E-2495.

ELECTRICAL FOREMAN, I. C. S. graduate. Seven years experience with construction, industrial and operating companies, desires responsible position with power company. Interested in electrical calculation and design. Age 23; married. Assoc. A. I. E. E. E-2496.

ASSISTANT TO EXECUTIVE. Young man, age 26, in firm where there is advancement. Have had electrical engineering education. First class references. Past five years with large public utility in maintenance department. Also have experience in accounting office of steamship company. Available on short notice. E-2497.

ELECTRICAL ENGINEER, technical graduate. Seventeen years experience in industrial and public utility work. Thoroughly capable and experienced in design and operation of high-tension transmission and distribution problems, also organization and supervision of meter work, underground and submarine cable systems to 22,000 volts, steam turbine and power house equipment. Desires permanent position with large industrial or public utility where there is chance for advancement. E-2498.

EXECUTIVE ENGINEER. Capable of taking charge of development of electrical and mechanical apparatus or position as factory manager or superintendent. Age 35; thirteen years experience. E-2499.

PRODUCTION MANAGER. I have prepared a booklet describing myself, and it will be sent on request to any manufacturer of electrical, mechanical or technical apparatus, who wants a man to take charge of manufacture. E-2500.

INDUSTRIAL ELECTRICIAN AND ENGINEER, I. C. S. graduate, age 35; married. Sixteen years experience in factory electrification, power generation, distribution, motor application, illumination, power plant, substation switchboard, automatic control, wiring maintenance and design, winding, assembling, testfloor, and laboratory experience. Reference past employers, desires position leading to permanency with industrial or operating company in U. S. E-2501.

SALES ENGINEER. Technical education; twelve years experience; motors and control, electric traveling cranes or similar equipment. Age 31. Location desired New York City. Salary $4000. E-2502.

ELECTRICAL ENGINEER, age 33, university graduate. Ten years experience in designing, distribution and construction of power plants, substations and transmission lines, desires permanent position with large company. Salary $200.00 monthly. E-2503.

BATTERY AND ELECTRICAL ENGINEER, Assoc. A. I. E. E. technical training, age 33; seven years submarine battery experience; exceptional experience in marine electrical installation; two years as superintendent of electrical shop U. S. Navy Yard; five years executive experience, familiar with all makes of storage batteries. E-2504.

GRADUATE ELECTRICAL ENGINEER, age 28. Five years experience in factory and office including three years G. E. test and two years general engineering work, such as investigations and reports on power and transmission problems, use of calculating table, power rates, etc. At present acting as technical advisor to chief engineer of large hydroelectric system. Desires position of greater responsibility and broader opportunities with hydroelectric company or for firm of consulting engineers. Salary $2500 to start. E-2505.

ENGINEERING EXECUTIVE, university graduate, G. E. test. Ten years experience in steam railway electrification, seven years in charge of development work with two manufacturing concerns. Excellent record. E-2506.

SALES ENGINEER, desirous of operating a number of carefully selected high grade non-interfering accounts in the vicinity of New York and for export to foreign countries. Fifteen years experience in professional and commercial engineering work. Successfully introduced a number of products and with existing organization in the position to quickly penetrate the trade with several new lines. E-2507.

ELECTRICAL POWER PLANT DESIGNER and field engineer, also experienced in maintenance and operation of central stations. University graduate with G. E. Test and four years electrical experience including layout and installation of transmission lines and underground distribution systems. Capable, energetic and resourceful. Present connection too limited. Age 30. Available ten days. Position desired in middle west. E-2508.

ELECTRICAL ENGINEER and assistant manager for Gas & Electric company serving territory of 50,000 population, desirous of employment with utility serving larger territory, or as manager of smaller utility. Twelve years experience in utility fields. E-2509.

WANTED position on the technical staff of a financial underwriting or analytical organization to investigate scientific technical and commercial soundness of industrial, public utility and other enterprises. Six years engineering experience. Large acquaintance among engineers. Member A. I. E. E. and A. S. M. E. Salary $6000 per year. E-2510.

ELECTRICAL ENGINEER, seven years on manufacture test, maintenance and construction of electrical apparatus including telephones, thermoelectric apparatus, meters, a. c. and d. c. motors and generators, synchronous converters, transformers, electric furnaces both for melting and heat treating purposes, power plant equipment, a. c. and d. c. motor control apparatus, etc. Have trained myself technically by studying during spare time as I progessed with my work. Am at present employed as construction foreman for large electrical manufacturing concern on complaint work. Available 30 days notice. Minimum salary $2500. E-2511.

INDUSTRIAL ELECTRICAL ENGINEER, 10 years experience in design, construction and operation of steel and industrial plants. Capable of assuming responsible charge of work. Married. Available immediately. E-2512.

ELECTRICAL ENGINEER, 1917 Illinois Electrical Engineering graduate, age 28, sound business training; six years of railway, power, shop and distribution experience. Salary $200.00 per month. E-2513.

GRADUATE ELECTRICAL ENGINEER, age 26. Three years electrical and mechanical engineering and test experience in large turbo-electric station, during which time handled correspondence concerning orders, etc. Desires position with firm of consulting engineers in connection with power plant design. At present employed; available on short notice. E-2514.

ELECTRICAL ENGINEER, technically trained, nine years practical experience station operation, electrical plant maintenance, design and improvement. Wide experience as draftsman with large textile manufacturer on factory electrification. Well qualified to design complete mill power and lighting installations. Expert industrial illumination. Age 30, married, excellent references. Associate A. I. E. E. Available February. E-2515.

ENGINEER-EXECUTIVE, desires semi-engineering, semi-commercial position. Now in charge manufacturing plant. Thorough knowledge Mexican conditions, political, commercial, geographical. Experienced in English and Spanish correspondence and translation; office management, oil prospecting, mapping, factory construction. Knowledge of French and German. E-2516.

MEN AVAILABLE

GRADUATE ELECTRICAL ENGINEER, Member A. I. E.E. Age 35; married. Six years assistant general manager of electrical construction company. Two years electrical officer in Navy; two years in sales department of manufacturing company. Desires permanent position in sales or administrative end of industrial concern. Opportunity for advancement of primary, and salary at beginning of secondary consideration. Location preferred East Coast. Available 30 to 60 days. E-2481.

INDUSTRIAL PLANT ELECTRICAL ENGINEER; graduate; age 30; speaks Spanish. Nine years experience in design, selection and ordering of material, construction and operation of electrical power and industrial equipment of large installations. Prefers proposition based on results attained. Seeks position offering great enough opportunities to warrant permanent residence. E-2482.

GRADUATE ELECTRICAL ENGINEER with two years experience in telephone field desires foreign service. Preferably in China or Japan, where telephone experience and knowledge of radio will be a decided asset. Age 24. E-2483.

YOUNG ELECTRICAL ENGINEER (1919) age 23, Spanish native tongue, with some technical and commercial experience, desires a position in Philadelphia. Willing to start at the bottom where there are good prospects of advancement. E-2484.

YOUNG MAN, engineer graduate (1919) desires position with electrical contractor, or as assistant engineer in industrial plant on maintenance work. Familar with work mentioned. E-2485.

GRADUATE ELECTRICAL AND MECHANICAL ENGINEER, age 32. Ten years experience both practical and executive, in the construction, operation, purchasing and management of a steel mill, power station and export propositions. Available on short notice. New York district preferred. Present salary $5000. E-2486.

ENGINEERING EXECUTIVE. Graduate electrical engineer. Extensive experience in construction, and operation of electric railways and power properties, also metal working factory management and syndicate work. Like opportunity, or with consulting construction or sales organization desired. Minimum basis $5000. Prefer less fixed amount with share or bonus proportionate to results. E-2487.

Graduate Electrical Engineer desires position with progressive business concern which will afford opportunity for advancement. One year designing and manufacturing automobile transformer coils. Ex-Army officer, energetic, amiable and dependable. E-2488.

Public Utility Engineer, superintendent or manager, experienced in design construction and management of gas and electric plants, long distance transmission systems, railways, etc., twelve years technical engineering and construction; six years operating management. Expert at rate making and experienced in handling municipal councils and state commission problems. E-2489.

Development Engineer. University graduate in electrical engineering 1919. Experience in development and supervisory work on manufacturing processes for large electrical manufacturing concern. Capable of taking responsibility of new developments where principles of physics must be practically applied. Middle western location preferred. E-2490.

AMERICAN SOCIETY OF LUBRICATION ENGINEERS

The American Society of Lubrication Engineers was organized September 22, 1920, at a meeting of engineers from the petroleum industry, the automotive industry and the oil equipment industry. The purpose of the Society as stated in the charter, is—

"To promote a better understanding of the problems of lubrication and the use of liquid fuels, including all problems of application and conservation."

The Society was granted a charter by the State of Illinois and a Constitution and By-Laws adopted. An official organ entitled *Scientific Lubrication* will be published and those members of the Institute interested may obtain a copy of the January number and other information by writing G. E. Fuller, Secretary, American Society of Lubrication Engineers, Monadnock Block, Chicago, Ill.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of anyof these members is requested to communicate with the Secretary, 33 West 39th Street.

1.—Leo Arany, Room 201 Parkway Bldg., Broad & Cherry St. Philadelphia, Pa.

2.—De Los De Tar, 411 East 15th St., Kansas City, Mo.

3.—Elliott, Electric Controller & Mfg. Co., Oliver Bldg., Pittsburgh, Pa.

4.—Alex. E. Kieth, 138 Elm Street, Hinsdale, Ill.

5.—H. S. Logan, 215-15th Street, Seattle, Wash.

6.—Leonard Morey, 1067 East 153rd St., Cleveland, Ohio.

7.—P. J. Reese, 7th & Main Street, Royal Oak, Mibh.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED JANUARY 14, 1921

Aabye, Jorgen, Danish Consulate, 8 Bridge St., New York, N. Y.

Abbett, Hugh Wheeler, Engineer, Public Service Comm. of Indiana, State House, Indianapolis; res., Oaklandon, Ind.

Adams, Frederic O., Works Supt., Lancashire Dynamo & Motor Co., Ltd., 45 Niagara St., Toronto, Ont., Can.

Anderson, Arthur H., 1811 Sixth Ave., Watervliet, N. Y.

Araujo, Cauby, Chief Engineer, Mayrink Veiga & Co., Rua Municipal 21, Rio de Janeiro, Brazil, S. A.

Armstrong, H. Vernon, Asst. Chief Draftsman, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

Bagnall, George E., Draftsman, The Detroit Edison Co.; res., 2181 Eastlawn Ave., Detroit, Mich.

Baker, Clark E., Electrical Engineer, Railway & Traction Engineering Dept., General Electric Co., Schenectady, N. Y.

Beach, Earl L., Primary Inspector, Detroit Edison Co.; res., 914 Lawndale Ave., Detroit, Mich.

Beck, Chas. J., Draughtsman, Elec. Dept., N. Y. Shipbuilding Corp., Camden, N. J.; res., 5829 Florence Ave., Philadelphia, Pa.

Benson, Henry W., Student Electrical Engineer, General Electric Co., Lynn; res., 6 Boston Ave., Somerville, Mass.

Beymer, Oliver H., Transformer Commercial Dept., General Electric Co.; res., 33 Edward Ave., Pittsfield, Mass.

Bisbee, Frederick C., Engineering Asst., Bell Telephone Company of Pennsylvania, 1631 Arch St., Philadelphia, Pa.

Blanton, Burt C., Mechanical Engineer, 406 Sumpter Bldg., Dallas, Texas.

Boruch, Edwin R., Student Engineer, Testing Dept., General Electric Co.; res., 67 Hull Ave., Pittsfield, Mass.

Carraway, Thomas W., Chief Engineer, U. S. Government Repair Unit No. 304, Camp Normoyle, Texas.

Conroy, Francis D., Electrical Draughtsman, Stone & Webster, Inc., 147 Milk St., Boston, Mass.

Cook, Querin H., Member of Firm of Meyer & Cook, 30 N. Dearborn St., Chicago, Ill.

Cox, Harold N., Draftsman, Ewart, Jacob & Byam, Ltd., 207 Excelsior Life Bldg., Toronto, Ont.

Cross, Samuel A., Asst. Electrical Inspector, N. Y., N. H. & H. R. R. Co., Van Nest; res., 420 E. 141st St., New York, N. Y.

Culligan, Michael, Asst. Transmission Engineer, Hydro-Electric Power Commission, Toronto; res., Port Credit, Ont., Can.

Dalas, Frank L., Chief Electrician, Cia. De Santa Gertrudis, S. A., Pachuca, Hidalgo, Mexico.

Dane, Francis W., Engineer in charge, Luthy Battery Sales Company of New England, Boston; res., Main St., Hamilton, Mass.

Danner, Roy, Chief Electrician, Wadsworth Mfg. Co., Detroit, Mich.

de Castillo, Edmond R., General Tester, New York Edison Co.; res., Hotel Endicott, West 81st St., New York, N. Y.

Dolen, David O., Power House Operator, Libby Water & Electric Co., Libby, Mont.

Droege, Harry G., Supervisor of Power & Lighting, Michigan State Telephone Co.; res., 69 Brown Place, Detroit, Mich.

Edmonds, Montrose, Quotation Clerk, General Electric Co., 1000 Lexington Bldg., Baltimore, Md.

Total 117.

ASSOCIATE RE-ELECTED JANUARY 14, 1921

KENT, JAMES M., Teacher & Consulting Engineer, Manual Training High School, Kansas City, Mo.

ASSOCIATE REINSTATED JANUARY 14, 1921

HUDSON, WALTER F., Chief Electrical Engineer, Utica Gas & Electric Co., 222 Genesee St., Utica, N. Y.

MEMBERS ELECTED JANUARY 14, 1921

ALLEN, ROY N., Vice-President, Supervising Engineer, Colby Steel & Engineering Co., 446 Central Bldg., Seattle, Wash.

CARTER, HERBERT G., Principal Assistant, Chief Electrical Engineer's Branch, Public Works Dept., Sydney, Australia.

COPP, FRANK T., Electrical Engineer, with H. N. Moody, 815 Perdido St., New Orleans, La.

FARMER, KENNETH V., Asst. Supt., Electric Dept., Syracuse Lighting Co., 335 S. Warren St., Syracuse, N. Y.

FULLER, JAMES C., Asst. Telegraph Engineer, Posts & Telegraphs Dept., Federated Malay States, Perak, Federated Malay States.

McQUOWN, WILLIAM K., Captain, United States Army, 1222 Munitions Bldg., Washington, D. C.

MICHELL, FRANK H., Chief Electrician, Langlaagte Consolidated Gold Mining Co., Langlaagte, Johannesburg, S. Africa.

NOBLE, EGERTON S., General Supt., Northern Canada Power Co., Ltd., Timmins, Ont., Canada.

PATCH, JAMES W., Designing Engineer, Transformer Engineering Dept., General Electric Co., Ft. Wayne, Ind.

SHOWALTER, JOSEPH, Consulting & Electrical Tests, Concord, Ont., Canada.

SINDEBAND, MAURICE L., Electrical Engineer, American Gas & Electric Co., 30 Church St., New York, N. Y.

SOUTHERN, GILBERT, Electrical Engineer, Mills, Rhines, Bellman & Nordhoff, 1234 Ohio Bldg., Toledo, Ohio.

TEMPLE, FRED REMINGTON, Outside Plant Engineer, Michigan State Telephone Co., 185 Cass Ave., Detroit, Mich.

WILMOT, LOUIS B., Consulting Engineer, Oceana Buildings, Simmonds St., Johannesburg, Transvaal, S. A.

TRANSFERRED TO GRADE OF FELLOW JANUARY 14, 1921

HAMILTON, JAMES L., Chief Engineer, Century Electric Co., St. Louis, Mo.

HIBBARD, HARRY L., Manager, Marine Dept., Cutler-Hammer Mfg. Co., New York, N. Y.

LILJENROTH, FRANS G., Consulting Engineer, E. I. du Pont de Nemours & Co., Wilmington, Del.

TRANSFERRED TO GRADE OF MEMBER JANUARY 14, 1921

ANDRUS, RAYMOND J., Operating Engineer, Central Power Co., Grand Island, Neb.

BOLSER, M. O., Technical Asst., Distribution Dept., Bureau of Power & Light, Los Angeles, Cal.

DOWNTON, PERCIVAL G., Branch Manager, Electric Storage Battery Co., Minneapolis, Minn.

DRAKE, CHESTER W., General Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.

FIRESTONE, SIEGMUND, Consulting Engineer, Rochester, N. Y.

GENT, RUFUS T., Plant Engineer, Hydro-Electric Power Commission, Niagara Falls, Ont.

LOCKYER, R. H. N., Engineer in Charge, West Kootenay Power & Light Co., Trail, B. C.

MILLAN, WALTER H., Supt. of Substations, Union Electric Light & Power Co., St. Louis, Mo.

NELSON, NORMAN C., Electrical Engineer, North Pacific Public Service Co., Bremerton, Wash.

NOTOMI, IWAICHI, Director, Shibaura Engineering Works, Tokyo, Japan.

POTTER, CHARLES P., Engineer in Charge, Large Motor and Transformer Engineering Depts., Wagner Electric Mfg. Co., St. Louis, Mo.

ROBERTSON, ARTHUR S., Erection Engineer, Hydro-Electric Power Commission, Niagara Falls, Ont.

ROSWELL, CHARLES M., Engineer, Charleston Consolidated Railway & Light Co., Charleston, S. C.

SIMONSON, GEORGE M., Chief Electrical Engineer, State of California Department of Engineering, Sacramento, Cal.

TAYLOR, EDWARD, Designing Engineer, General Electric Co., Chicago, Ill.

VOLKMANN, WILLIAM, JR., Assistant to Chief Engineer, Toronto Power Co., Toronto & Niagara Power Co., Toronto Railway Co., Toronto, Ont.

WARNER, WILLIAM H., Distribution Engineer, New York & Queens Electric Light & Power Co., Long Island City, N. Y.

YAMBERT, D. W., Electrical Engineer, France Stone Co., Toledo, O.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meeting held January 3, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

RIDDILE, J. S., Manager of Power, Laurentide Power Co. Ltd., Grand Mere, Quebec.

To Grade of Member

ANDERSON, OSCAR V., Superintendent, Distribution Dept., Toronto & Niagara Power Co. and Toronto Railway Co., Toronto, Ontario.

BAKER, CAREY W., Engineer, Transformer Dept., Canadian Westinghouse Co., Hamilton Ont.

BEAUBIEN, JAMES DE GASPE, Consulting Engineer, Montreal, Quebec.

COLE, HORACE L., Engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

CORIELL, LOUIS D., Periodontist and Radiologist, Baltimore, Md.

HAISLIP, RICHARD A., Telephone Engineer, Dept. of Development & Research, American Telephone & Telegraph Co., New York, N. Y.

HEWSON, WILLIAM G., Railway Engineer, Hydro-Electric Power Commission, Toronto, Ont.

HOLMES, HOWARD A., Engineer, Morris Knowles, Inc., Pittsburgh, Pa.

KENT, JAMES MARTIN, Teacher and Consulting Engineer, Manual Training High School, Kansas City, Mo.

SEABURY, RICHARD W., President, Boonton Rubber Mfg. Co., Boonton, N. J.

WALTER, HENRY C., Electrical Engineer, Allis-Chalmers Mfg. Co., Milwaukee, Wis.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before February 28, 1921.

Albright, John A., Jr., Syracuse, N. Y.
Allen, Asa E., Dallas, Texas
Alson, C. Robert, Milwaukee, Wis.
Andrews, Ralph J., Jackson, Mich.
Aschenbreuer, Rudolph, Milwaukee, Wis.
Ashenden, Harry B., Milwaukee, Wis.
Aspinwall, George L., Boston, Mass.
Bailey, George L., New York, N. Y.
Baker, Charles F., Charleroi, Pa.
Baldwin, Benjamin W., St. Paul, Minn.

Vol. XL MARCH, 1921 Number 3

The Effect of Heat on Paper Insulation

BY H. W. FISHER and R. W. ATKINSON

Both of Standard Underground Cable Company.

A discussion is given in detail of the mechanical properties of paper especially as influenced by drying, heating, and impregnating. Tests for measuring the changes due to these causes are discussed and it is shown that tensile tests are unsatisfactory for this purpose. A measurement of tearing resistance is found to be satisfactory and two machines for this purpose are described. Measurements are given of rate of deterioration of paper at different temperatures. The relation of these data to allowable operating temperature is considered.

No discussion is given of the various causes including heating due to dielectric losses which affect the limiting temperature of high-voltage cables.

The rapid increase of deterioration with temperature is shown. Emphasis is placed on the importance of not exceeding intended temperatures through lack of knowledge of conditions.

IN a discussion of the limiting temperature for paper insulation of low-voltage cables, the matter for first consideration is the effect of high temperature upon the properties of the material. The principal importance of this effect lies in the reduction of the mechanical strength of the paper. In the case of low-voltage cable, the only changes in electrical properties of importance are incidental to the mechanical changes and therefore a discussion of these mechanical changes forms a complete basis for consideration of temperature limitation.

The deterioration of paper due to continued high temperature is not measured by change of tensile strength of the paper. The change is apparent in reduced ability to withstand tearing forces, or bending or folding. Satisfactory study of aging of paper can be made only with the use of suitable apparatus for measuring one or more of these properties. This article includes description of instruments for this purpose as well as data of a considerable number of tests made on paper, after various kinds of heat treatment, as described.

Following the report of experimental data is a discussion of the question of temperature rating of this class of insulating material. The effect of high temperature upon the impregnating medium is not considered in detail except in-so-far as the rate of deterioration of the paper may be influenced by the medium.

If a quantity of paper of uniform quality is subjected to a high temperature and successive samples are taken from it, from time to time, it will be found that the successive samples differ progressively in ability to withstand tearing between the fingers, or to withstand without breaking, creasing or bending. The first effect noticeable is the greater ease with which the paper is torn. Later samples may not be creased without cracking. With a further degree of deterioration, it is actually not possible to bend the paper an appreciable amount without breaking. A still further amount of aging produces a material which crumbles to a powder. If the successive samples of paper are subjected to a tensile test made very carefully so as to avoid injury of the nature of incipient tears, or unequal tension on the specimen, it will be found that even those samples which show an evidently reduced ability to withstand tearing, will have as high a tensile strength as originally. In a number of samples which have been subjected to high temperature for sufficient time to produce a very marked decrease in tearing resistance, it will be found that, even though the tensile tests are made very carefully, there will be a wide variation in the strength measured for the individual samples. The maximum readings may be practically as high as the original strength of the paper, though tests on other individual samples fall as low as 40 or 50 per cent of the original value. The fairly apparent cause of this condition is the great difficulty of obtaining an actually fair tensile test on the very brittle material so that only an occasional specimen will show the real tensile strength of actually something near the original value. Of course, as deterioration is increased still farther there is an actual reduction in tensile strength as well as in loss of tearing resistance.

We may now consider the essentials of a suitable method of measuring aging. The requirements are not peculiar to this particular measurement, but they are very frequently overlooked and it is well to make a specific mention of them so as to make a clearer examination of testing methods with these requirements in mind.

Presented at the 9th Midwinter Convention of the A. I. E. E. New York, Feb. 16-18, 1920.

The first requirement is that the property measured is actually a measure or at least an indication of the usefulness of the material to meet the required service conditions.

The second essential of the method of test is that it shall permit definite distinction between samples which are different only in a slight degree. That is, the difference in the measurements of two such samples must be large in comparison with the variations in the measurements on samples which are identical. This constitutes effective sensitivity.

The third requirement is that the measurements be such as to be capable of permanent record and preferably of a definite quantitative form. It is in this particular that the tearing test by hand is unsatisfactory though it meets the first requirement and, to a fair extent, meets the second one.

We believe it is fairly generally recognized that a tearing test by hand meets the first requirement, that is, it measures or indicates the usefulness of paper to meet the service conditions of cable practise. It is well-known in the art that paper containing only the amount of moisture normally present when exposed to the dry air prevalent indoors in winter time, is much more difficult to run in cable wrapping machines than is paper exposed to the high humidity prevalent in summer weather. Also, it is recognized that if paper insulation is damaged by overheating after application to a cable, it is less able to withstand handling and bending such as is incident to installation.

Therefore, a method which shows progressive difference with moisture content and with aging at high temperature, meets, at least as far as concerns these variables, the first requirement of a suitable paper testing device. In any event it fulfills this requirement as far as concerns measurement of aging. It follows from what has been said that a measurement of tensile strength by the ordinary method is quite unsuitable from the standpoint of this first requirement.

From the standpoint of the second requirement, tests of tearing resistance even by hand are fairly satisfactory. Until very recent years, there has been no machine as suitable from this standpoint as the hand test. We will later describe two machines which are very satisfactory from this standpoint. The tensile test is unsatisfactory also from the standpoint of the second requirement.

The difficulty in the way of securing consistent results with a tensile test, on account of accidental damage, etc., suggested the use of a method of testing by damaging the specimen in a certain definite way and then making a tensile test. Such a method of test was standardized by making a transverse cut in the paper for a distance equal to one-quarter of the width of the paper. Tensile tests were then made upon the modified samples. Somewhat more satisfactory results were obtained by noting the elongation of the specimen before rupture, than by noting the tensile strength obtained. This method was in use for some time but was never more than partly successful and has now been abandoned for methods described later.

A machine for testing the tearing resistance of airplane fabric was given in a discussion by F. J. Hoxie at the annual meeting of the American Society of Mechanical Engineers in December 1919. We quote his very brief description: "Tear tests were made on a horizontal testing machine by cutting the specimen three in. wide and placing them in three in. jaws with one in. of cloth between the jaws at the front of the machine and three in. between them at the back." We have seen this method applied on cloth with very satisfactory results. As the test was further developed a transverse cut was made in the cloth on the stretched side before applying the tension test.

A similar problem to that of paper is encountered in the insulated cable industry in the case of varnished

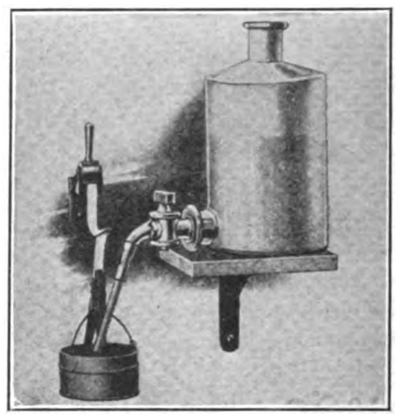

Fig. 1

cambric. It was found that frequently a high tensile strength was found on samples which were obviously inferior from the standpoint of use and also from the standpoint of tearing resistance as measured by hand.

In the attempt to find a suitable machine for testing this material, a type of machine much used in paper testing, a so-called "pop tester," was tried. We were much surprised however to find that the results with this type of machine were quite in accord with the tensile tests and thus did not rank the material in the same order at all as its practical usefulness or as the ranking by tearing resistance as made by hand. The machine used for these bursting tests was one using liquid pressure against a rubber diaphragm which in turn pressed against a strip of the cloth under test. Tests of less extent made on paper showed similar results as far as they were carried. There is a published record of a similar experience of another experimenter with the use of this machine for testing paper. (H. N. Case in the *Journal of Industrial and Engineering Chemistry*, page 49, January 1, 1919.) It is interesting that this writer found the "bursting

test" machine, or "pop tester," a useful addition to his testing equipment, but found that sometimes a desirable test condition is the combination of a high tearing resistance with a *low* test with the "pop tester."

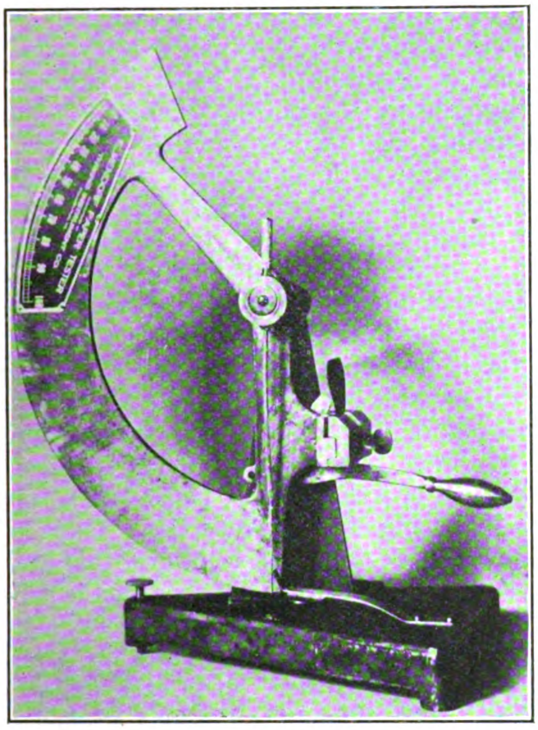

Fig. 2

In the same article is described a "home-made" machine for measuring tearing resistance. Details of test results as used for determining usefulness of paper for various applications, are given. Fig. 1 shows the apparatus described and used by Case. A method developed by the writers and described below was suggested by the successful results obtained by Case with his machine. Case's machine is also of interest in its close resemblance to the apparatus used by Mr. W. A. Del Mar, which I believe will be described in his paper presented at this symposium.

Description is given in an appendix, of the tearing testing machine developed by the writers and on which was obtained much of the data reported herein. This machine differs in the most important degree from the machines of Case and of Del Mar in that the measure of the tearing resistance is made by the use of a spring as a dynamometer instead of by means of a weight in a pan. We refer to this instrument as machine No. 1.

Just before the actual preparation of the manuscript of this article we secured a machine which seems to be practically an ideal instrument for measuring tearing resistance. The instrument, which is illustrated in Figs. 2 and 3 and described in the appendix to this article, is made by the Thwing Instrument Company of Philadelphia. We refer to this instrument as machine No. 2. It is pertinent to remark that this machine is not a certain older type made by this concern and on the market for sometime. We have not had any experience with the older type. This machine No. 2 differs from all previously described instruments for measuring tearing resistance in that each single measurement of the machine determines the average tearing resistance over a considerable length of paper. On this account when measurements are made on a uniform paper, individual readings differ by only small amounts and thus the average of a very few measurements can be repeated with great exactness on a second lot of similar samples. A further advantage of the machine is the facility with which tests can be made and the simplicity of the testing itself.

Study of the tearing resistance test as we have made it with either No. 1 or No. 2 machine indicates that it is a very satisfactory method of comparison of similar samples, or of samples which differ in only one important particular. Thus it is possible to rank accurately samples from the same original lot, but differing at the time of test in moisture content, or in length of time subjected to various aging conditions. Without further evidence, however, it does not necessarily follow that two samples differing in several particulars, but giving the same tearing resistance, are equal in usefulness. Thus we might get the same tearing resistance on a sample originally of high resistance, but subjected to an aging test, as on a sample originally of poorer quality but not subjected to the aging test.

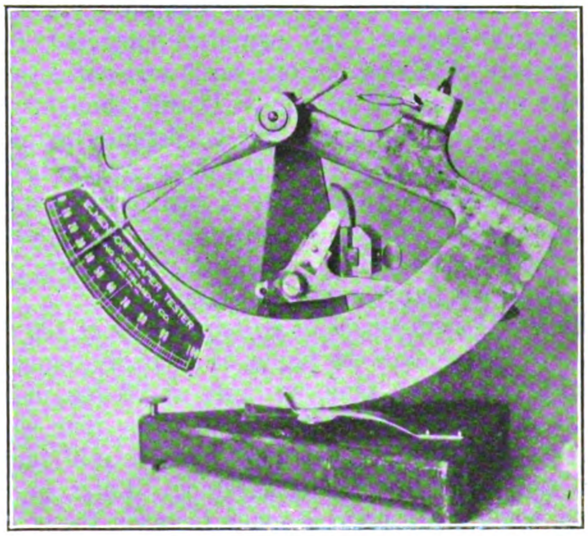

Fig. 3

Undoubtedly, the measurements of the instruments we have used are of very great value in making comparison even under such an instance as this, but conclusions to be drawn from tests of samples from different sources and under different conditions must not be considered complete or final without a further analysis of the matter.

Before describing recent tests made with the aid of a tearing resistance machine we will describe some very old tests made by one of the authors during 1905. These tests are of very considerable importance for two reasons. They constitute an important part of the basis for the present temperature rating of paper cables. Second, though they are in agreement with some other tests reported by other observers, they point to materially different conclusions from most of the other tests reported in this paper. Suggested explanation of some of the difference is given later.

In this series of tests, sealed samples of lead-covered cable were heated for a period of respectively one week and four weeks, one lot at a temperature of 100 deg. cent., and one lot at a temperature of 93 deg. The samples were submerged in a bath of melted paraffin, heated by a gas flame. The temperature was controlled by means of a thermostat (bi-metallic spring) which controlled a solenoid operating a valve controlling the gas. The thermostat was sensitive enough to respond to less than one-fifth deg. cent. When the temperature was lower than the setting of the thermostat, it closed the circuit for the solenoid causing it to open a valve so that the gas flame was strong enough to raise the temperature to the setting of the thermostat, after which the solenoid would release and reduce the gas flame to the lower limit and allow the temperature to fall.

It will be understood that, at the time of making these tests, there was not available any testing machine as good as a test of tearing with the fingers. The results of the test are however definite to a fairly satisfactory degree. The samples subjected to a temperature of 93 deg. for one week were not deteriorated by an important amount. It was thought that some change had occurred, but no definite assurance of this was found. However the deterioration in four weeks' time was so much that it was considered that we could not think of recommending operation at that temperature. The temperatures above, and throughout the paper, are in centigrade.

The samples subjected to a temperature of 100 deg. cent. for one week were found to be badly damaged, probably about the same as those at 93 deg. in four weeks. Those subjected to 100 deg. for four weeks were found "rotten." The paper was so stiff that it could not be bent without breaking. Later in this article, some comparison is made between these tests and more recent ones.

These tests were reported in sub-committee meetings of the Standardization Committee of the Insitute and, together with supporting information from other sources, are the basis of the present temperature limit of 85 deg. cent. as given in the Standards of the Institute for low-voltage paper cables. The temperature of 85 deg. was chosen as a safe amount lower than the test temperature of 93 deg. which resulted in serious injury to the insulation in four weeks.

Before discussing the effect of heat upon the mechanical properties of paper, it is well to say a word about the effect upon its composition. If paper in its natural condition is dried at say 100 deg. cent. for a short time, or at a lower temperature and under vacuum, it will lose up to nearly 10 per cent of its weight in moisture. This easily removable moisture is sometimes called "moisture of condition." If paper is exposed freely to the atmosphere, the moisture content will vary with the humidity and temperature of the air. Thus paper exposed to air in an ordinary heated room in the winter time contains very much less moisture than similar paper exposed freely to outdoor air in the winter, or to air in the summer time. Accompanying this change in moisture content, and doubtless caused by it, there are important changes in the mechanical properties of the paper, as will be shown. If the heating of the paper is continued at high temperatures for long periods of time, longer time being required at relatively lower temperatures, there is a continued and slow loss of weight of the paper and a continued change in its mechanical properties. These changes are very similar to the changes however that are undergone when only the moisture of condition is driven off.

Tests of tearing resistance of paper were made under a wide variety of conditions. Tests on several different kinds of paper were made each under several conditions. The different conditions studied include effect of moisture content and of saturation with different kinds of compound and a study to determine the part played separately by the saturation and by the drying where a sample is subjected to both drying and saturating. Aging tests were made on samples exposed to air and on samples submerged in two different kinds of compound.

The first striking fact in connection with these tests is that impregnation itself affects only very slightly the tearing resistance of the paper. The cause of the great loss of tearing strength when the sample of paper is dried and impregnated is the change in moisture content and is not due to the impregnation with compound. Tests of the tearing resistance of paper dried for a short time in oven and of similar paper dried by immersion in compound at 125 deg. showed practically the same result. Some more careful comparisons were made as follows. Paper was dessicated under vacuum and at room temperature. One lot was tested dry, one lot after saturating with "lectroseal" transformer oil, and one lot after saturation at 80 deg. cent. in the petrolatum compound which was used in the tests. The sample in transformer oil was about 10 per cent weaker than the dry sample. Samples impregnated with petrolatum compound have shown as much as 35 per cent greater strength than dessicated samples. In other cases the difference has been slight.

Another lot of paper which had not been treated and was merely exposed to air at 30 per cent humidity wa

divided into three lots. A lot which was impregnated in cold transformer oil was found to have exactly the same strength as the original sample which was not treated. Another sample was impregnated in petrolatum compound at 80 deg. cent. and was found to be 24 per cent stronger than the original sample. As four papers were grouped together during the tearing test, it was thought that adhesion between the samples might have been responsible for the increase of strength. Some of the original paper and some of the impregnated paper were tests with only a single sheet. With single sheets the impregnated paper was 18 per cent stronger than the original. Thus, perhaps a portion of the increase was due to the cause suspected.

The next striking fact to be observed is the extremely large variation in tearing resistance with change in moisture content of the paper. Thus, a given sample of untreated paper was subjected to an atmosphere of approximately 100 per cent humidity. A similar sample was subjected to a vacuum, both samples being treated at ordinary room temperatures of about 20 deg. cent. The tearing resistance of the second sample was less than 40 per cent of the first sample. Samples exposed to air of different degrees of humidity show intermediate tearing resistance.

With the paper tested and with the oils used, and for the relatively short series of tests which were made, there is an astonishingly small difference between the aging effect at a given temperature of paper submerged in oil and the paper exposed to air in an enclosed vessel, either sealed or unsealed. This is contrary to the usual understanding that the deterioration in air is much greater than under oil. However, some observers have reported the contrary, namely, that deterioration is more rapid under certain classes of oil than in air. Such differences as we have found are not entirely consistent and thus there is room for further study of the matter. In general, the tendency seems toward a higher rate of deterioration under oil than in air at high temperatures and where the periods are very short. For longer periods of time, the rate of deterioration seems to tend to be a little greater under oil, (but the difference is not of very great amount). In any comparison which we so far have made, the difference has not been greater than the difference due to perhaps five degrees variation in temperature.

The above paragraph applies specifically to a simple mixture of 80 per cent commercial petrolatum and 20 per cent commercial resin. Tests were also made with a mixture of 80 per cent commercial resin oil and 20 per cent commercial resin. Commercial differences in the ingredients do not have a very important effect upon the particular property under consideration, namely the aging of the paper. Therefore it is considered that the test with these two specific mixtures will represent fairly well the result to be expected with most of the impregnating media which are in extensive commercial use. Tests were made with similar lots of paper in the respective types of compound and at 125 deg. cent. for periods of one week and two weeks. The results indicated a greater rate of deterioration in the resin oil compound. The difference was not large and we do not consider the results conclusive, except so far as they indicate that the difference in the effect of the kind of saturating medium is not very great; not as great as would be caused by a temperature difference of 5 deg. cent.

Measurements of the aging of several different kinds of paper, were made. There is a fairly definite variation obtained with different samples of standard grades of Manila cable paper. For comparison, some Kraft paper composed of wood pulp was tested, also a sample of Bond writing paper. These last named samples were much lower in original strength, but the percentage of reduction due to the aging was of the same order of magnitude as for the Manila. The decrease in tearing resistance at 125 deg. was as great on one sample of Manila paper as would be expected with the best Manila paper at a temperature of perhaps 10 degrees higher, and for the same time. From the standpoint of aging, no paper was found better than the paper which furnished the basis for the curves in Figs. 4 and 5. Even though the deterioration of a sample of low original strength is not at a higher rate in terms of the original strength, the paper would be at all times, weaker than another sample of better original quality.

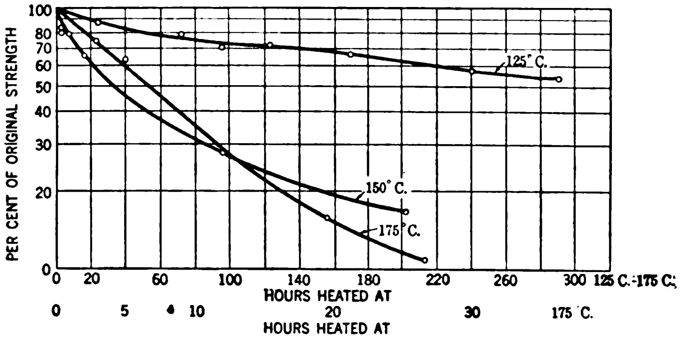

Fig. 4

In Fig. 4 are given three curves showing the loss of tearing resistance at 125, 150 and 175 degrees respectively. In the case of the 175-degree curve, the tearing resistance of the samples, tested before opportunity for reabsorption of moisture from the atmosphere, in terms of the strength of the original paper dessicated under vacuum at room temperature, is plotted as ordinates. Number of hours aged is plotted as abscissas. The tests at the other two temperatures were made on samples which had been allowed to come to equilibrium as regards moisture, in air at about 30 per cent humidity and 20 degrees temperature. The ordinate in these two cases is expressed as the tearing resistance in percentage of the original tearing resist-

ance of the paper, with it also in equilibrium as regards moisture content with atmosphere at 30 per cent humidity. As all the samples had been exposed together to the atmosphere for a long period of time the conditions were similar. Tests were made on some of these samples aged, after dessication and in comparison with dessicated but unaged original samples, and the percentage of strength based on these figures is not materially different from those plotted, in Fig. 4. For purposes such as now under consideration, values determined as for the 175-degree curve would be preferred.

From the data of the curves in Fig. 4, Fig. 5 has been constructed as showing the relation between temperature and number of hours required to produce certain definite amounts of deterioration. Each curve on

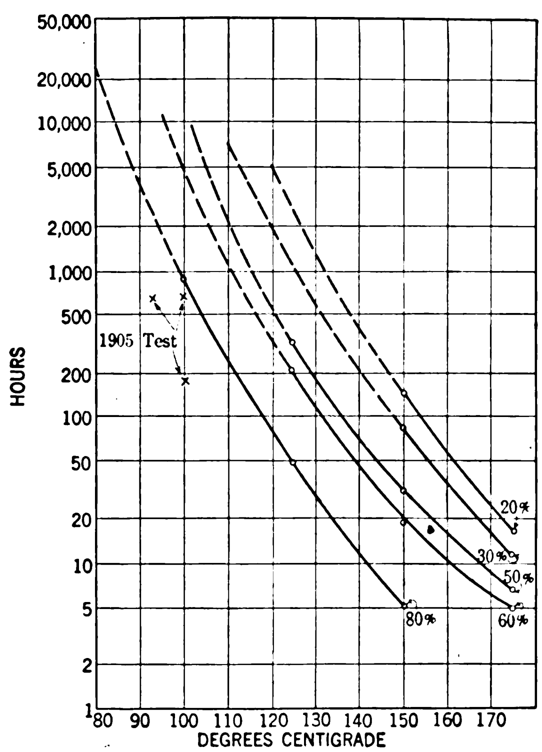

FIG. 5

Fig. 5 represents a certain definite amount of deterioration and shows the length of time required for the tearing resistance to fall to a certain percentage of the original tearing resistance. Thus, the lowest curve shows the time required to come to 80 per cent of the original tearing resistance. The three points indicated by a cross belong to another series as will be mentioned presently.

A point on one curve in Fig. 5 is given at 100 degrees. This is from a test on paper saturated in petrolatum compound and maintained at 100 deg. for 37 days.

It will be noted that the scale of time is logarithmic and covers several decades. The curves have been extrapolated at the left-hand side with the idea of estimating time required for deterioration at lower temperatures with correspondingly very long time. Of course it is recognized that extrapolation is likely to cause serious errors in conclusion and therefore these conclusions must always be interpreted with caution. If some additional points are obtained at the higher temperatures, and particularly if points are obtained at lower temperatures than those at which most of the tests were made, it will be quite reasonable to expect fair accuracy of extrapolation into the range of temperature with which we are most concerned. Even with the data as now presented, some important conclusions can be drawn.

It is interesting and important to note that the different curves approximately parallel each other. The slope of these lines is of perhaps as much importance as the actual numerical values. Thus, it will be observed that the rate of deterioration doubles for a temperature increase of about 8 deg., at temperatures near 125 deg. Within range of 100 deg. and lower, the increase of rate of deterioration with temperature is even greater. Thus, as the lower curve in the figure is drawn, the rate of deterioration is doubled in about 5 deg. increase of temperature. These rates correspond respectively to increasing the rate of deterioration tenfold in about 25 deg. and about 15 deg. respectively. That is, the rate of deterioration at 100 deg. is roughly ten times as great as at 85 deg.

As the curve is drawn, an appreciable deterioration (about 20 per cent) is shown at 85 deg. in about nine thousand hours, that is about one year. In case the extrapolation is wrong and the deterioration at 85 deg. is much lower than thereby indicated, the slope of the curve is greater and the increase in rate of deterioration with temperature is even greater than the figures named in the preceding paragraph.

On the basis of the slope of the curve as drawn, in Fig. 5, may be determined the effect of intermittent loading at high temperature. Thus the annual rate of deterioration of a cable loaded so as to produce a temperature of 100 deg. cent. for about two and one-half hours per day and a temperature much lower than 85 deg. for the rest of the day will be about the same as that of a cable loaded continuously so as to produce a temperature of 85 deg. Now it is not improbable that the rate of deterioration at 85 deg. is materially lower than as indicated in Fig. 5. If that is correct, then an intermittent load producing a temperature of 100 deg. cent. for some shorter period than two and one-half hours would be equivalent to a continuous load producing a temperature of 85 deg.

If the continuous loading produces a high temperature, followed by higher temperatures for short periods, the deterioration due to both conditions must be considered. Thus, on the basis of the specific values given in Fig. 5, the rate of deterioration of a cable having a temperature of 100 deg. for two and one-half hours per day, and of 85 deg. for the remaining time would be nearly twice as great as for a continuous temperature of 85 deg.

We may now refer again to the 1905 tests previously described. While of course, as stated, no permanent record could be kept showing the degree of deterioration of the paper in the 1905 tests, the following method of comparison was used. Samples which were aged recently and had been measured, were compared with the recollection and description of the aged paper of the old tests in an attempt to obtain some rough numerical value for the deterioration obtained in those tests. Little doubt was entertained that the sample which had been maintained at 100 deg. for four weeks, was as bad as recently tested samples, which had been reduced by aging to 30 per cent of their original tearing resistance. On this basis, the deterioration obtained at 100 deg. in the old series of tests was as great as would be expected from recent tests at 125 deg. in the same length of time. This difference in temperature is large as compared with the uncertainty of the comparison, and we may thus consider that roughly the relation just stated exists between the old and the new tests.

It is important to consider the possible causes of this large difference. It is not unlikely that part of the difference lies in the paper itself used with the two tests. There is an apparent possibility of accounting for perhaps 10 deg. of the difference in this way. The data for the curves in Fig. 5 are based largely on tests on saturated paper exposed to air; the 1905 tests were upon samples of cable saturated with resin oil and sealed in the lead cover. The apparent greater rate of deterioration obtained in recent tests on resin oil saturated samples as compared with petrolatum saturated samples, or perhaps with samples exposed to air, may account for another part of this difference. This is particularly true as there was some evidence in the recent tests of a greater rate of deterioration at temperatures lower than 125 deg. of samples saturated in compound than those exposed to air.

A further point of difference between the old tests and the new is that the old tests were made upon an actual cable sample which had undergone a certain amount of aging in the process of manufacture, whereas the recent tests were upon paper not subjected to such preliminary aging. The shape of the curves in Fig. 4 would tend to point to this fact as not helping to account for the difference, but the reverse. That is, a sample loses a greater percentage of its original strength in a period of given length after the beginning of the aging than it does in a second equal period, even with the loss of strength in the second period expressed in terms of the strength at the beginning of that period. However, in a study of the possible reasons for the different results obtained, this difference in the manner of tests should not be overlooked. We are not at all inclined to be satisfied that the three possible causes mentioned are sufficient to account for the difference between the old and the new tests.

Even after there are available sufficient experimental and laboratory data as to the degree of deterioration occurring at different temperatures and under different conditions, there still remains to be determined what is an allowable amount of deterioration from the standpoint of operation of the cable. As the deterioration is continuous and gradual and as there is no temperature at which there is a sudden change in the rate of deterioration, any definite limit to deterioration which is set will be arbitrary. We will now consider the matter of limitation, in the light of operating experience and operating demand.

It is known that cables have been in service for long periods of time and with various degrees of deterioration of the paper even up to practically complete carbonization. In most cases where such conditions existed, we believe that not a very large amount of cable has been thus affected. Thus while there are numerous individual examples of cable samples which have been found to operate successfully with a large degree of damage to the insulation, there is actually in service a comparatively small number of feet of such cable. Thus there is not any extensive record of the serviceability of cable in considerably damaged condition. Furthermore, it is probable that such cable furnishes a large proportion of the operating failures that are not due entirely to external injury, an amount of failure insignificant in comparison with the amount of such cable in service. Furthermore, such cables may fail in service from injury due to causes which would not be harmful to good cable. Though examples of this sort are cited as evidence of how far the deterioration may be carried without causing electrical failure, we do not believe that it is the policy of operating engineers to recommend operation which may be expected to produce this condition in any short term of years.

Many of the cables known to have operated successfully after severe overheating have had very liberal insulation thicknesses. This fact has an important bearing on their successful operation after being damaged. Thus if an attempt were made to standardize an operating temperature which would produce any material deterioration of the insulation it would need take into account the liberality of insulation in proportion to the operating conditions.

One viewpoint of the operating companies is evidenced by the attitude of some of them with regard to cable specifications. We will refer particularly to the recently published specification of the N. E. L. A. Underground Systems Committee, which was produced after extensive conference with many engineers representing different parts of the industry. In the discussion preliminary to that specification, the operating engineers emphasized very strongly the importance of the ability of a cable to withstand installation under severe conditions, removal from the duct line if necessary and reinstallation, again under severe conditions. It is not to be thought that extreme sacrifices

would be made to insure the ability to reinstall especially under severe conditions, but we know that it was emphasized as an important matter.

In view of this attitude, it would seem unreasonable for this Institute to standardize operating conditions which would materially reduce the serviceability of cables from this standpoint. It is proper however, for the Institute to recognize that operating conditions will sometimes exist which will make it a matter of economy and of good engineering to operate at temperatures expected to produce rapid deterioration and probable short life. It may be cheaper and better practise to replace cable at intervals when necessary than to put into service from the beginning, a much greater amount of cable. Or it may pay to load a cable to such an extent that there will be rapid deterioration, though reasonably long life will be expected provided it is not moved or mechanically disturbed. A single example of such a condition is where initial temperatures are very high and thus where a relatively slight increase of temperature would permit a very great increase of current rating. This subject is not for detailed consideration at this time, but is a matter which must be decided by each cable user on the basis of ultimate economy. The data furnished at this symposium regarding deterioration at higher than ordinary working temperatures, will be of great value in the analysis of such special cases.

As a definite suggestion in line with the above discussion, it is submitted that the Committee assign a temperature limit which may be expected to produce a reduction of 20 per cent of the original tearing resistance of the paper after a period of say five years' time. Supplementing this, higher temperatures may be named which will produce the same annual rate of deterioration if the temperatures are maintained for a certain corresponding number of hours per year.

This specific suggestion, together with the specific data in Fig. 5 will lead to the following temperature limits:

For continuously maintained temperature	78 degrees
For maximum temperature maintained five hours per day, temperature during remaining part of day low	85 degrees
For maximum temperature maintained two and one-half hours per day, temperature during remaining part of day low	90 degrees
For maximum temperature maintained one-half hour per day, temperature during remaining part of day low	100 degrees

It is to be expected that there will be available to the Committee additional information which will confirm or modify these suggested values.

It has been remarked that cable failures have resulted from the motion of cables due to contraction and expansion with variation of temperature, resulting in cracked sheath and ultimately in failure due to entrance of moisture. It has been reported that satisfactory means for preventing this difficulty have been found. Cable users should be cautioned in regard to this matter and should be informed as to the preventative methods.

Where data are available concerning any considerable length of cable which has been severely damaged in commercial service by overheating, it will be of particular value if any unusual phenomena are reported. For example, in tests made by one of the authors in 1913, a 100-ft. length of cable was heated to a temperature such as to produce rapid deterioration. It was found that a large amount of gas escaped from the ends which were at first unsealed. Accordingly, terminals were attached to the ends so as to prevent the escape of the gas, and a steam gage was attached so as to register the pressure inside the sheath. This pressure reached a value of about 100 lb. per sq. in. at which pressure the sheath burst and the pressure was relieved by the forcing out through the hole of a large amount of compound and gas.

In the recent series of tests, where samples were sealed in lead tubes, some difficulty was experienced in maintaining the seal tight, and there was considerable evidence of internal pressure. This information points to a possible limitation of amount of allowable deterioration quite aside from the changing properties of the paper itself.

It is worthy of particular note that, for ordinary conditions, much more is to be lost by operating at a temperature a few degrees too high than by operating at a few degrees lower than the maximum allowable temperature. For example, based on an earth temperature of 20 deg. and an operating temperature of 85 deg. a change of 5 deg. in the operating temperature will be produced by a change of current rating of only 4 per cent under ordinary installation conditions. But an increase of 5 deg. above the correct limiting temperature will result in a shortening of the life by one-half. Therefore, an accurate knowledge of actual temperatures of cables is a requisite for obtaining maximum performance without danger of material reduction in life of the cables.

Without a margin of safety in the temperature rating, the importance of accurate knowledge of temperature conditions or proper allowance for want of this knowledge is of fundamental importance. Neglect of this will lead to cable damage far more costly than a sacrifice of carrying capacity due to operating at even less than the safe maximum. Thus in rating cables for current it is important to leave whatever margin is necessary to insure that uncertainty in knowledge of conditions does not cause an excess of temperature.

Acknowledgment is made to Mr. F. E. Coxe for valued work during the series of tests just concluded and to Mr. N. C. Davis for the investigation of the "pop-tester."

APPENDIX

Machine No. 1 is essentially a very light vertical tension testing machine having a maximum reading, or automatic recorder. The scale was read as centimeters deflection but a calibration was made in grams by hanging weights from the dynamometer spring.

Standard samples were prepared for test as follows. Strips of paper usually one inch wide were cut in lengths of 7¼ in. Five holes ¼ in. in diameter were punched along the center line of the paper and about ⅝ in. between centers, the first hole being about ⅝ in. from one end. From the other end a cut was made with scissors to within ¼ in. of the last hole. From the end of that hole to within ¼ in. of the next a cut was made with a razor blade. This was repeated for each hole.

Test was made after clamping the free ends on each side of the scissors cut in the jaws of the testing machine. The maximum force required to tear from the cut into the next hole was read for each of the five holes. The average of fifteen readings taken on three samples of paper constituted a single test.

Other forms of test sample were used at an earlier date but the above was especially useful as giving a considerable number of tests so as to give a good average within a small sample and in a reasonable time.

In the description of the No. 2 machine, we quote largely from a statement by the maker of the machine.

The machine is known by the maker as the "Elmendorf Paper Tester." It was finally perfected in the Forest Products Laboratory of the United States Forest Service. It is the understanding of the writers however that the makers of the machine have added some improvement since making the statement which we quote in the previous sentence, and that these improvements are embodied in the machine with which we have worked.

The testing machine simulates the action obtained by one method of hand testing on paper when a sample piece of paper is torn between the fingers in order to "sense" the average tearing force. The instrument consists essentially of a weighted pendulum which, in swinging from a predetermined height, tears the sample to be tested and indicates the tearing strength of the paper by the amount its swing is retarded.

Briefly, the machine operates as follows. A certain number of samples of the paper to be tested (generally four in our tests) are selected, each 6 cm. long and 3 or 4 cm. wide. (Our tests were made on samples 1 in. wide). The samples are then set in the machine and held in the clamp as shown in Fig. 2. A knife on the machine is made to cut a slit in the paper, giving a start for the tear. The cut is a definite distance of 2 cm. thus giving a distance of 4 cm. for the tear.

The pendulum is then allowed to fall and as it does so, it tears the paper as indicated in Fig. 3. As the tearing action proceeds, the motion of the pendulum is retarded by an amount proportional to the work done in tearing the paper. For each grade of paper tested, the pendulum will therefore rise to a different height on the right. The lighter the paper and the less work required to tear it, the higher the pendulum will rise, and the heavier the paper, the less the pendulum will rise. The greatest height to which the pendulum rises on the right is registered by a pointer and can be read when the pendulum comes to rest. This reading is a measure of the work done in overcoming the tearing strength of the paper through the length in which it was torn. It is proportional to the average tearing strength of the paper when the number of papers and the distance torn are constant.

In using machine No. 2 for measuring tearing resistance, usually four pieces of paper were tested simultaneously and the total length of the tear was 4 cm. The individual readings thus gave the average resistance for the four papers. Most of the data recorded are the average of four individual measurements. As this gives an average of the tearing resistance of 64 cm. of paper, it may be expected that the results will be capable of very exact duplication for uniform paper. This is further illustrated by the following. On twenty different measurements, each the average of four or five individual tests, the numerical differences between individual measurements and the average of all were taken. This difference was expressed in per cent for each set of readings. The average of these average differences of twenty tests was 4 per cent, the maximum was 11 per cent. This was on a very brittle (aged) sample. No other difference exceeded 8 per cent. It seems reasonable therefore to expect that the error of the measurement of any sample taken should seldom exceed 5 per cent and that the probable error of any result did not exceed about 2 per cent.

However, it has been found that samples tested on different days under conditions considered identical have given differences of as much as 20 per cent. The difference is attributed to variation of paper at different parts of a roll which was evidently not entirely uniform in tearing resistance. Of course, wide variations are to be expected if moisture content is allowed to vary and it is very hard to keep this under control. The variation of 20 per cent was found however in the case of two sets of samples which were dessicated by drying in a vacuum at a temperature of about 20 deg. cent. It is not known at this time just how much influence small changes of temperature or small changes in the residual pressure in a vacuum chamber may have affected these results.

With the No. 1 machine for measuring tearing resistance, we considered the limit of probable error of the measurement of the actual samples under test, to be about 10 per cent.

Superpower and its Relation to Industry

BY HENRY FLOOD, JR.

Engineer-Secretary Superpower Survey

THE SUPERPOWER idea is not new. It is only the expansion of present central station practise greater in magnitude, but not more complex in structure. It is the replacement of small scale by quantity production.

While great progress has been made in reducing power costs and in conserving fuel by the central station systems of this country, there is still much that can and must be done along these lines. The recent war made many thinking men realize that notwithstanding the improvements that had come into operation during the last ten years, there was still a vast waste both of fuel and money going on in this country in the production of power, and some of these men who had a greater visionary power further realized that these very wastes would become a tremendous handicap to us in the competition for the world's markets which has followed after the war.

These wastes have been recognized and have been frequently discussed, but to Mr. William S. Murray the credit must be given for bringing the country from out of the period of discussion into that of positive action.

The North Atlantic seaboard was the region selected for the first Superpower Survey, and the reason for such a selection being made is not a hard one to find. This section of the country, which is known popularly as the superpower region, embraces the territory along the North Atlantic seaboard from about Portsmouth, New Hampshire, to Washington, D. C., and extends inland on an average of about 150 miles. Geographically, it is a very small portion of the country, as it contains only about 2 per cent of the total land area. From the standpoint of population it is important, as about 22 per cent of our inhabitants live within its borders. According to the recent census, 75 per cent of the people in those states of which the superpower region is a part, live in cities and towns, while for the balance of the country only about 41 per cent are city dwellers. But most of all its importance to the country's needs stands forth from its industrial activity, as nearly 40 per cent of the total value of manufactured products come from this region, and about 35 per cent of all the country's power is generated within its boundaries.

This industrial supremacy can easily be visualized from the fact that one out of every eight persons living therein is an industrial worker, while for the balance of the country we find only one out of every 25 persons so employed. New England is even more intensely developed from the industrial view-point, as there one out of every 6.4 persons is a wage earner in factories.[1]

Another measure of the industrial activity of the superpower region is shown by the output of manufacturing products, which was $314 per capita in 1904, and $390 per capita in 1914, while the balance of the United States produced manufactured articles to the value of only $113 per capita in 1904, and only $190 per capita in 1914.

This intense industrial development results in a very large demand for power to operate the industries and to provide the transportation both for the raw materials into the region and for the finished products to the peoples living without the region; hence it was logical to select this region as the one in which could best be shown the merits of a regional power system.

The history of our power development has been truly remarkable when compared with that of other countries. It has grown from a period where we had practically nothing but small isolated plants, to the present era where we have large central station companies serving extensive areas and population. However, today these companies are for the most part segregated and have either no connection with their neighbors or only very light connections where the interchange of power is principally for breakdown purposes. It is very seldom that we find these connections between the central station companies such that power may be interchanged with a view toward a more economical operation of the participating companies.

Superpower goes a step in advance. It provides a regional system through which all of the large load centers within its boundaries will be linked together by means of heavy trunk transmission lines capable of carrying sufficient power so that each power plant can be operated in the manner necessary to get the greatest resultant economy to the entire region.

It provides for the construction of large base load steam electric plants located at tide-water, on inland rivers, or in the coal mining territory, as conditions may warrant.

It makes possible the construction of hydroelectric developments at potential water power sites, the development of which is not now advisable with the conditions existing on our present power systems.

Superpower does not consider the abandonment of present central station systems. They are the nucleus about which a superpower system would be built up. While the older and more expensive plants will have to be gradually abandoned, the larger

Presented at the Worcester Section Meeting, A. I. E. E., Feb. 2, 1921.

1. Information derived from U. S. Census reports.

and more efficient plants will become an integral part of a regional system for furnishing power.

Superpower visualized is but a large power reservoir into which will be fed the output of the more efficient existing plants, the proposed new base load steam electric stations, and the hydroelectric stations; and from which the power to supply the industrial, the railroad and domestic requirements of the various load centers will be tapped where and when needed.

As great as are the power requirements of the region today they are small compared with those of tomorrow. The unassociated total power requirements have increased from about 15,000,000,000 kilowatt-hours in 1910 to about 27,000,000,000 kilowatt-hours in 1920, with a corresponding increase in machine capacity of from 8,600,000 kilowatts to approximately 14,800,000 kilowatts.

It is estimated that the power growth for the next decade will increase the total energy requirement to about 50,000,000,000 kilowatt-hours, and assuming the superpower system to be in operation, about 18,700,000 kilowatts of machine capacity will be required to satisfy this load.

Of these above power requirements electric public utilities furnished in 1920 about 12,000,000,000 kilowatt-hours with a machine capacity of 4,000,000 kilowatts, and it is predicated that by superpower operation the power to be furnished from central supply sources will grow to about 36,000,000,000 kilowatt-hours by 1930, and will require a machine capacity in the neighborhood of 9,000,000 kilowatts.

These estimates which are conservative, call for 5,000,000 kilowatts additional power plant capacity in the central supply systems during the next ten years, an increase of 125 per cent over that which we now have in existence.

In making these preliminary estimates, consideration has been given to the fact that part of the manufacturing industry today receives its energy directly by water power, and further that it will be undoubtedly found unprofitable to take over to a superpower system certain isolated plants in manufacturing industry which have use for large amounts of steam for process and heating work. Furthermore, it is realized that only a certain amount of the track mileage of the heavy traction railroads will have traffic sufficient to justify electrification, so that only those portions of the railroads have been included which can profitably be electrified.

In manufacturing industry the estimated power requirement of 1920 was placed at 12,400,000,000 kilowatt-hours, and it is estimated that the central station systems supply about 2,750,000,000 kilowatt-hours of the total requirement. By 1930 it is conservatively estimated that the total power load of manufacturing industry will increase to about 19,000,000,000 kilowatt-hours, and that of this total, superpower can economically furnish at least 10,000,000,000 kilowatt-hours, or slightly over 50 per cent of the total. While making these load estimates it has been realized that there are certain possibilities of the future, such as the extensive use of electricity for furnace work and heating. What growth will be contributed by any such developments is purely conjectural—accordingly it has not been included.

The region supports 36,000 track miles of heavy traction railroad system. Of this it is estimated that from about 6000 to 8000 track miles can be justified for immediate electrification. The present requirements of the electrified portions of heavy traction railroads are about 500,000 kilowatt-hours per year, and it is estimated that the power requirements of the electrified portions will grow to about 6,000,000,000 kilowatt-hours by 1930, considering only those portions of the railroads where electrification can be justified either through the savings effected or by the gain in increased capacity for traffic.

One of the prime effects of a regional system would be the better utilization of our nation's fuel supply.

Few persons realize that of our total coal resources only about 16 per cent lie in the Eastern province, that is within easy freight transportation distance of our North Atlantic Seaboard; and furthermore, I believe fewer people appreciate that out of the total coal mined to date about 75 per cent has been withdrawn from the coal fields lying within this province.[2]

While considering that these particular coal fields even when supplying the greater part of the country's coal requirements still have many years of existence, we cannot ignore the fact that the comparatively rapid depletion of this field as compared to the others is fast working a hardship on this paticular section of the country through the agency of advancing coal prices, brought about by the exhaustion of the higher grade and more cheaply mined coal seams within this particular province. That coal will be very much cheaper for extended periods than it is at the present time seems hardly likely in view of these conditions; in fact, all of the evidence points to just the reverse.

The coal user seldom decides his policy of coal utilization from the standpoint of national conservation, but rather upon what the cost of power will be to himself. The relatively higher coal prices that have existed for the past four years have had their effect through making it essential for the coal user to conserve his coal in order to keep his costs down.

From the studies made to date by the Superpower Survey, it is indicated that the central station systems within the region paid an average of about \$5.40 per net ton for bituminous coal delivered. The engineers of the survey have made a very careful study as to what the probable average cost of bituminous coal will be during the ten-year period from 1920 to 1930, and as a result of their consultation with the recognized

2. Data from U. S. Geological Survey, Professional Paper 100-A.

authorities on the subject of bituminous coal, they have come to the conclusion that the average cost of coal at the mine for that period will be higher than that which was in force in 1919, and that the freight will probably not vary greatly from the present rates, which are 40 per cent in excess of those paid in 1919.

Had superpower been in operation in 1920 a saving of about 30,000,000 tons of coal having a value of about $162,000,000 could have been effected, through its economies over the present performance of central stations, steam locomotives and isolated manufacturing plants, and by 1930 the superpower system should effect a saving of 53,000,000 tons per annum with a value of $286,200,000 when compared with present practise.

Despite the estimated savings given above, the load growth of this particular region is such that by 1930 at least 14 per cent more coal than is now being used for power production purposes will be required to take care of a superpower system, and the other power production facilities that would be left in the region. The argument has often been advanced that a superpower system would have a very serious effect upon the railroads, of making idle the vast investment in equipment through the removal of the coal haulage from their lines, but these figures show that this fear is absolutely unwarranted.

With regard to coal, the superpower offers also another great advantage. It will be the greatest stabilizer of the coal industry through large coal storage areas at each of its base plants, thus placing a more uniform demand for coal upon the mining sections. Those of you who are familiar with some of the elements of cost of coal mining will appreciate the importance to the coal mining industry of any such agency.

The war brought about a number of changes in our power practise. The cost of power producing equipment went up and deliveries were long delayed. The price of coal rose rapidly and not only was it scarce but often great annoyance was encountered in obtaining it. The country was calling for production, and then more production, and as a result of these contributory causes the manufacturer turned to the central station for his power requirements as never before. He accepted central station power and devoted the money he would have spent in building and operating his own power plants to the actual producing of his product.

The war, furthermore, has changed the economic position of the country. Previous to it we had gone to Europe for large amounts of money to develop our vast natural resources, and consequently we were in debt to her. The war reversed this position. Not only was it necessary for us to liquidate our debt to Europe, but in addition we found it necessary to advance her funds so that today we are Europe's creditor to the extent of about ten billion dollars.

It is conceded by our ablest financiers that this debt must be paid largely through the agency of goods rather than gold, and our own industry therefore will be thrown into direct competition in the home markets with nations employing cheap labor.

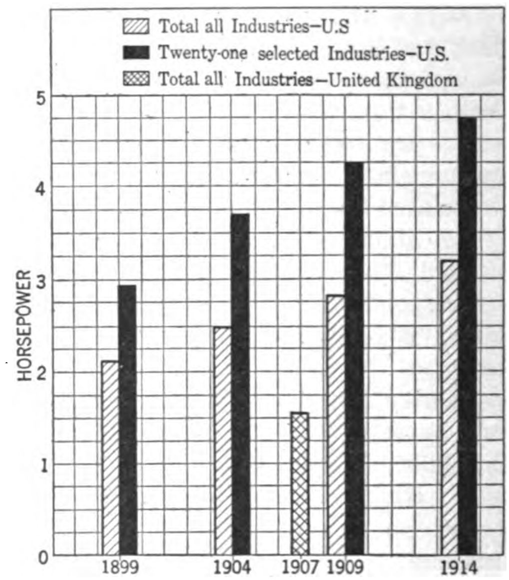

Fig. 1—Horse Power per Wage Earner in Manufacturing Industries in United States

One further effect of the war has been that our industrial production facilities have been increased so that their output cannot be absorbed by our home markets if all of their facilities are to be kept employed. The ratio of our exports of manufactured products to raw materials was very much larger for 1920 than

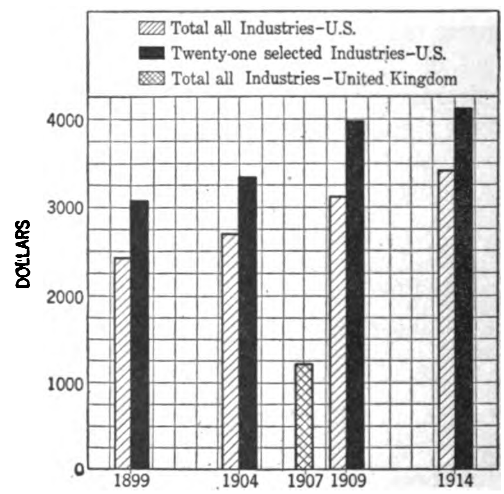

Fig. 2—Value of Products per Wage Earner in Manufacturing Industries in United States

in any pre-war year, and this is as it should be, for the exports of manufactured articles represent the employment of more of our labor at home. However, it brings us face to face with competition against the cheap labor of the rest of the world, and to maintain our position as leaders in the world's markets, it is necessary that we make our more expensive man power

cheaper than that of the balance of the world through the agency of added machine power.

In the decade between 1904 and 1914 our machine power per industrial worker increased from 2.5 h. p. to 3.2 h. p., and at the present time it is estimated to be over 3.5 h. p. In 1907 Great Britain used 1.55 h. p. per wage earner. During the same decade the value of products per wage earner in this country increased from $2700 per annum to $3430 per annum, while Great Britain in 1907 produced manufactured products to the value of only $1220 per annum per industrial worker. The relation between machine power and the output per wage earner is thus strikingly brought out, and on its face shows one of the reasons for our successful competition with the cheap labor of Europe.

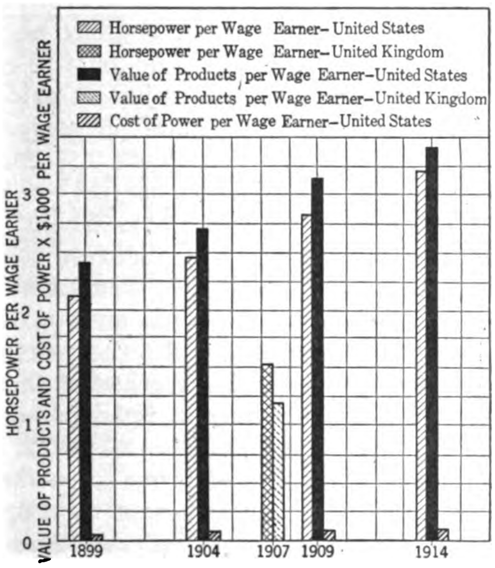

Fig. 3—Horse Power, Value of Products and Cost of Power per Wage Earner in Manufacturing Industries in United States

The superpower region is comparable to England inasmuch as both may be considered finishing shops. The superpower region contains 355 classified types of industries, of which 36 use 77½ per cent of the total power and 76 per cent of the total coal. Complete records are available for only 21 of the 36 industries, but these records disclose the fact that in 1904 these 21 industries used 3.7 h. p. per wage earner, and in 1914, 4.7 h. p. per wage earner. The corresponding value of products per annum per wage earner was $3340 in 1904, and $4135 in 1914.[3]

The foreign nations who are our competitors have recognized that the weakness in their industrial system is the lack of adequate machine power facilities, and they are feverishly working to correct this situation.

England in 1918 undertook a study of its power conditions, and as a result of the reports made by the Committee on Electricity to the Board of Trade there has been set up a definite power policy under governmental supervision, by means of which she hopes to bring her power facilities to a parity with our own. The British Isles have been divided into thirteen natural power districts under the authority of a Board of Electricity Commissioners, which has the power to direct the character and magnitude of all future electrical generating or transmission facilities, whether they be in central supply service or in isolated manufacturing plants. It is interesting to note that in the report of the Committee on Electricity to the Board of Trade, it is stated, "Investigations have shown that in the United States of America the amount of power used in industries expressed in terms of the number of operatives employed, is greater than in this country. In practically all of our industries, the h. p. per operative could be increased with advantage both to the capital and to labor, as is shown by the results obtained in the United States of America where both the net horse power per operative employed and the standard rates of wages are higher."

While the form of centralized control adopted by England will do much in furnishing her with an adequate and standardized power supply, the initiative in this country should come from the private interests rather than through governmental control or ownership, particularly in view of our recent experiences with such control or ownership.

Switzerland is taking active steps to make available more power for her industries, while Holland, Italy, and France are doing likewise.

In Germany, an extensive scheme, one in fact comparable to our proposed superpower system, is actually being constructed and placed in operation. The German plan provides for very large plants located at the coal mines and calls for the conversion of as much of the coal as is possible directly into electrical energy. It further provides for the organization of the different industries such as the textiles, the chemical industries, and others into associations which will negotiate their power requirements and prorate the use of the various individual plants. The plan is one of copartnership between private enterprise and the Government, and takes into consideration, giving capital an incentive for good management and for the rapid development of the coal mines to provide additional electrical energy. The central idea back of the scheme is to provide adequate and cheap power for the manufacture of goods intended for export.

If we are to successfully compete with these European countries having cheap labor, who have in addition recognized the value of mechanical power, we dare not stop at any figure of power utilization in our factories of 3½ h. p. per wage earner, but we must keep the differential between the machine power used in this country and that abroad at least equal to what it is today.

3. Derived from U. S. Census Bureau Reports.

The cost of power is a small proportion of the total cost of producing a manufactured article, and when this is considered with the facts we have just brought out it is very evident that the average manufacturer can obtain far bigger returns by improving the application of power with reference to increased production than he can by creating economies in the cost of power generated by himself.

Superpower recognizes the fact that if our industry is to compete in the world's markets, power in unlimited quantity must be made available to industry; it recognizes that the quality of service is of paramount importance, and therefore in laying out the tentative system one of substantially heavier construction than has ever been used in this country is being considered. It takes into consideration the fact that industrial success is dependent to a large degree upon transportation, and it provides the means for the increase of transportation to satisfy industrial demands through the electrification of those portions of our heavy traction railroad systems where the traffic density is such that electrification will either create a saving in the cost of operation, or create additional traffic capacity through its ability to handle the traffic more rapidly.

The regional power system advocated by Mr. Murray is basically sound. That large savings will accrue from it is evidenced by the savings already effected through the extension of our central station structure.

These savings of both money and fuel accrue from a number of causes. The regional system permits advantage to be taken of the diversity between the peak loads of the several districts, and allows the use of joint reserve equipment in place of the segregated reserves to much greater magnitude now required.

Through industry and the railroads the saving is brought about by quantity production displacing small scale production, and further by the ability of the regional system to take over their loads having an inherent load factor of not over 15 per cent, and by so doing raise the regional system's load factor to the magnitude of 50 per cent.

The pooling of the large part of the power in the region has a beneficial effect on the cost of both steam-electric and hydroelectric power, as it permits the use of highly efficient base load steam-electric plants operating at very high-capacity factors, a condition which cannot be obtained except on the very largest of our present electric utility systems together with the use of hydroelectric power for carrying peak load.

As is well-known the rivers in the eastern portion of the United States are subject to great variation in flow, and few of them are adapted to the operation of base load power. Their development has heretofore been retarded by the very fact that no such power reservoir as that proposed in the superpower system has been available for their output, and the creation of such a reservoir will bring the opportunity for the development of these potential water powers.

In conducting its study, the Superpower Survey has recognized as a fundamental principle that the franchise rights and investments of the existing electric public utilities must be respected and safeguarded. The function of a superpower system is to furnish the interlinking system only and to provide such generating stations, either steam-electric or hydroelectric, as can be justified from the standpoint of a lower production cost only. Its operations must cease where those of the electric public utilities begin, that is at the buses of the principal load centers.

It is very evident, particularly in the earlier stages of a superpower development, that it will be more economical for such a system to receive energy from the newer and more efficient existing central station plants where such energy can be obtained above their own requirements, than it would be for it to construct its own plants. Per contra, it is just as evident that certain of the older and more expensive plants must be abandoned, in order to reach the lowest cost of power and the greatest fuel conservation, but the replacement of these plants should not take place until the margin of saving between superpower and power of the abandoned plant is sufficient to allow for the abandoned plant's gradual amortization over a period of years out of the savings so effected. It is only by such a method of the gradual retirement of capital, that the interests of present investors can be protected.

In this connection, and of prime importance, will be the presentation in the report of the Superpower Survey of a chronology in the order of their requirement of the first and following locations of superpower stations and their attendant transmission lines. Data already analyzed indicate the immediate size and location of stations, and from this start, which will be financially self-supporting, there will be developed the extension of the system into its whole.

The principles that have governed the expansion of our city and territorial power system are entirely applicable, only in a higher degree of magnitude, to the regional system for the superpower zone. The size of power producing units and attainable voltages are such that it is no longer required that these units be placed side by side, joined by a common bus under one roof, but may be made to come into intimate relation with each other although separated 300 miles; and vast as the superpower system may seem, such a visualization of it will, I believe, serve both to simplify its aspect as well as to show that a regional situation must be met by a regional plant.

There are many phases of the problem with which the Superpower Survey is dealing, which are equal in their importance to the establishment of the physical possibility of such a scheme, and these questions dealing with the legal and financial aspects and inter-

corporate relations are being given serious consideration by the Advisory Board and its sub-committees, composed of the most able and highly respected men in the United States in their several capacities.

Industry is represented upon this Advisory Board by Mr. Magnus W. Alexander, Managing Director of the National Industrial Conference Board, and it is unnecessary to tell you his qualifications for this position as they are nationally known.

The Engineering Staff and the Advisory Board both have from the inception of the work appreciated its tremendous importance to the country, and they have felt, therefore, that even with the caliber of the men associated with the work it was very necessary to call into consultation the country's best talent, so that the report when made, will represent not alone the findings of those engaged in its actual formulation, but will have behind it the weight of the advice of the country's most highly developed experts in engineering, law, and finance.

The least that the report of the Superpower Survey can do is to show clearly what the trend has been for the past ten years in the electrical power field of this region, and what may be expected and must be provided for in the next decade. What is more probable however, is that its report can be used as the basis of a national power policy, and for the particular region studied that an actual form of corporate procedure can be set up for the accomplishment of the plan and the realization of the benefits to be derivedfrom it.

Private interests must recognize the necessity for adequate and economical power development if they are to avoid the governmental influence that has occurred in Great Britain. When Mr. Murray's report is made—and if the conclusion is that the utilities, industry and the people as a whole will benefit by such unification as is the basis of the report—then the private interests must act—quickly and effectively—to retain the control of the utilities which has been theirs in the past through their aggressiveness and good management.

SOME ELEMENTS OF THE ELECTRON THEORY OF MATTER

Abstract of an address by Professor Vladimir Karapetoff of Cornell University*

Prof. Karapetoff emphasized the point that it is easy enough to evolve a theory that would explain various known facts *qualitatively*. The real difficulty consists in assigning such numerical values to the various parts of the assumed mechanism that widely differing facts be satisfactorily explained *quantitatively*, without contradictions. A mathematical analysis of experiments is necessary in order to derive such numercial values. Those who set out to become familiar with the electron theory usually get discouraged not because the hypotheses involved are too complicated, or the leading experiments too obtuse, but because the mathematics which accompany the treatment seem too advanced or not convincing. For this reason the speaker devoted his lecture to the elucidation of some of the mathematical methods used in modern electron theory.

According to this theory an electron is an elementary particle charged with negative electricity, or actually consisting of negative electricity. Atoms of matter are supposed to be built up of such electrons and of a positively charged nucleus in the center. An atom in its structure is similar to a solar system. First of all the speaker showed how the charge on an electron may be computed to a high degree of precision from the well-known "oil-drop" experiments of Professor Millikan. Then he showed how the speed and the ratio of charge to mass of an electron may be determined from J. J. Thomson's experiments in a cathode-ray tube. The radius of the electron is then readily computed from these data, using ordinary laws of mechanics and electromagnetism.

Next the speaker touched upon the mathematical theory of "chaos", when electrons or molecules, or both, fill an enclosed space. Using the theory of probabilities he deduced Maxwell's law of distribution of velocities of molecules and electrons, which law serves as a basis for many important computations in the electron theory. Brownian movements in gases were treated next and Einstein's fundamental formula was deduced from which the number of molecules in a cubic centimeter of gas can be computed from observation of microscopic irregular motions of a light suspended particle in a gas.

Finally Professor Karapetoff spoke of what he called one of the triumphs of the electron theory, namely Bohr's model of an atom and his theoretical confirmation of the frequencies of the lines of hydrogen spectra from a nebula, to within one tenth of one per cent. "The Electron theory is bound to play a more and more important part not only in physics and chemistry, but in electrical engineering as well. Theories will change, but it is time for younger engineers and physicists to become familiar with the fundamental in controvertible experiments and with the principal methods of mathematical analysis of electronic motions. Otherwise these men will soon be hopelessly out of date."

*Delivered before the Pittsburgh Section of the A. I. E. E., February 8, 1921.

MIRRORS FOR OSCILLOGRAPHS

Recently the Bureau of Standards, Washington, D. C., has developed a new method for producing very small and light mirrors for use on oscillographs. Sometime ago an attempt was made to produce these mirrors from aluminum, polishing the metal in the usual way. However, it was found that the metal was too soft to be satisfactorily polished and some other means had to be devised which would give a better and at the same time as light a mirror. The process, as finally worked out, consists in pressing the aluminum between two optically flat steel dies. The mirrors thus made are highly polished with the surfaces sufficiently plane to produce satisfactory images of the spot of light.

Present-Day Practise Limitations of Oil Circuit Breakers

By the Sub-Committee on Oil Circuit Breakers and Switches of the Protective Devices Committee*

H. R. WOODROW, Chairman
Stone & Webster, Inc., Boston

IN ORDER to summarize the present-day indefinite operating requirements and limitations of oil circuit breakers, the A. I. E. E. (Protective Devices Committee), N. E. L. A. (Apparatus Committee) and Electric Power Club (Power Switchboard and Oil Circuit Breaker Section) cooperated in sending out a joint questionnaire for oil circuit breaker data to the larger operating companies. The response to this questionnaire was prompt and rather complete, which is an indication of the interest taken by the operating companies.

This subject has been given careful consideration in the past and several papers have been presented, and still there remains much research work to adequately determine the proper limitations of design and application. To this end it is suggested that operating companies add to their systems, equipment which will register essential transients that can not be registered on the usual quota of indicating and recording meters. On account of lack of generator capacity and operating complications, it has been impossible to test oil circuit breakers to any great extent to determine their limiting rupture points and consequently the circuit breaker of today is based largely on deductions from the results of system trouble, the conditions of which are usually of rather indefinite nature. At the present time, however, the operating companies are showing an increasing willingness to cooperate with the manufacturer in the development of oil circuit breakers by allowing constructive tests to be made on the generating equipment of their systems.

We feel that the results of this cooperation will lead to a marked improvement in that it will make possible the elimination or correction of a number of minor defects, which in the few tests that have been made have been shown to be a factor in causing previous failures.

In the paper on "Rating and Selection of Oil Circuit Breakers", by Messrs. Hewlett, Mahoney and Burnham, presented before the A. I. E. E. in February 1918, the basis for the present day manufacturers' standards was outlined, and we propose to summarize in this report the operating companies' viewpoints of these standards, as brought out in the replies to these questionnaire, together with recommended revisions.

The general requirements for oil circuit breaker specifications have been classified as follows: first, rated voltage second, rated continuous current-carrying capacity; third, rated momentary current carrying capacity; and fourth, rated interrupting capacity.

Rated Voltage

Insulating requirements are fairly well established, but, nevertheless, there have been some failures due to the inability of the oil circuit breaker to withstand voltages encountered under operating conditions. Some of these failures have resulted in serious explosions, due to the vaporizing of the oil and the igniting of this explosive gas mixture; some have been caused by bushing trouble and others by breakdown of the insulating material.

It would seem that the present test requirements, as specified by the A. I. E. E. standards, of 2. 25 times operating voltage plus 2000 volts may not be severe enough for the larger moderate-voltage system. Some operating companies are using oil circuit breakers of higher voltage ratings in order to secure better factors of safety; and further consideration should be given to raise the present voltage test requirements. These tests are usually made under clean, dry conditions, whereas the circuit breaker is subjected to abnormal conditions at the time of its operation when the breaker is apt to be covered with moisture and often dirt, in the case of outdoor breakers; and particularly with breakers in cell structures it is apt to be surrounded by gas which does not have the same insulating qualities as dry air. This condition also holds for the inside of the breaker where under test the insulating medium is dry, clean oil having a high dielectric strength. Moisture is found in the oil of any breaker after it has been in operation a short time and there is a certain amount of deterioration of the oil which is accelerated every time the breaker ruptures short-circuit currents.

A breaker is also apt to have impressed across its terminals potentials considerably above the normal voltage of the circuit. As an illustration, the disconnection of a circuit with synchronous equipment at both sides of the terminals allows the two systems thus sepa-

E. M. HEWLETT	ARTHUR SIMON

H. R. WOODROW, Chairman

Presented at the 9th Midwinter Convention of the A. I. E. E., Feb. 16-18, 1921.

rated to drop out of step and at times will be put in opposite phase relation, thereby producing double voltage across the contacts.

We would suggest that the oil circuit breaker standard potential tests be investigated with an idea of increasing this test value. These tests should be made between all live parts to ground and between phases under conditions for minimum clearances.

Rated Continuous Current-Carrying Capacity

There has been little trouble reported of oil circuit breakers overheating under normal operation, although the reports indicate that some operating companies order oil circuit breakers with current rating above their requirements. This has probably been a wise policy as it allows a greater margin of temperature rise in the breaker under short-circuit conditions and a greater margin of safety. Some trouble of overheating has been reported which has been caused by poor workmanship, such as poor alignments of contacts. It would be a great help if the contacts were made for greater ease and permanency of adjustment.

In order to reduce the maximum temperature and to prevent accumulation of explosive mixtures in cell compartments which has given some trouble, we would recommend that careful consideration be given to ventilation of compartments cautioning at the same time against ventilation which would allow gas from one compartment entering an adjacent cell. One company has found it desirable to carry the ventilation from each tank to the outside of the building.

Rated Momentary Current-Carrying Capacity

Trouble has been experienced by some of the larger operating companies through the failure of oil circuit breakers to carry heavy short-circuit currents for the period of time required to open the circuit and in some cases of the inability of the current-carrying parts to withstand the strain produced by the electromagnetic forces. We are very fortunate in having the accompanying paper by Mr. Torchio which outlines the results of a very extensive series of tests along these lines, showing very conclusively certain weaknesses in oil circuit breakers from this standpoint. The principal weaknesses brought out in these tests have now been corrected.

It is recommended that all oil circuit breakers be given a short-circuit current rating for a period of say both one and five seconds which should be at least equal to the interrupting capacity and in most cases two to three times this value. The manufacturers should test each line of their breakers or make periodic tests of breakers as they are brought through the factory which would cover this rating, these currents should be of relatively low voltages, thereby requiring a small generating capacity. These tests should also include the current-carrying capacity of the auxiliary contacts for the duration of time they would be required to carry the heavy current after the parting of the main contacts.

Rated Interrupting Capacity

The limiting factors entering into the operation of an oil circuit breaker when interrupting a current have never been conclusively determined. The present-day practise of rating oil circuit breakers to interrupt a given r. m. s. current at normal voltage two times at a two-minute interval and then be in a condition to be closed and carry its rated current until it is practicable to inspect and make necessary adjustments, is not in accord with operating requirements as reported in the replies to the questionnaire. There is considerable difference in the operating requirements depending upon the character of the system. On such parts of a system as will not cause interruptions to service by the opening of an oil circuit breaker, it is general practise not to throw in the breaker again until the circuit is tested and in some cases until the breaker is carefully inspected as well. In other cases where the opening of an oil circuit breaker interrupts service such as distribution feeders, single transmission lines, etc., there is a general tendency to throw in the breaker as soon as possible without testing the circuit. In many cases, the latter method restores service, as the opening of the oil circuit breaker may have been caused by a flash-over or other intermittent trouble. In some of these cases the operators find that even after the breaker has opened automatically, two, three, four and some as high as five times, a reclosing of the breaker will restore service, and, therefore, they feel it desirable to have the breaker rated to withstand this service.

Considerable time is required in testing a feeder, and in many cases the only available means is by closing the circuit through the oil circuit breaker. In some cases, however, this heavy requirement on the oil circuit breaker could be relieved by the installation of proper testing facilities, particularly where there are many feeders or points of high power supply.

It is felt that the interrupting capacity tests that are being made at the present time in the factories and on some of the larger companies' systems will give a better idea of the limitations of the oil circuit breaker to withstand the stresses produced by the reclosing feature. Also the installation of recording devices on systems which will give some record of the service imposed on a breaker under short-circuit conditions should lead to progress in the design of oil circuit breakers.

Some companies consider it desirable to compare the constants of the circuit breaker, such as tank dimensions, length of break, speed of operation expansion chamber etc., before selecting one for their conditions, and it is hoped that the results of the above tests will tell us more regarding the relative importance of these features.

It is felt that the manufacturer should, as soon as possible, give a rating on oil circuit breakers on the single-shot basis and proportion these ratings on the reclosing basis. By single-shot basis is meant interrupting of the current, as defined in the next paragraph, and the switch being capable of reclosing and carrying full-load current. As an example, a breaker rated at a certain value on the single-shot basis would be rated at a somewhat lower value on a two-shot basis, and other values below this on a three-shot, four-shot, etc., basis.

There is considerable difference of opinion as to what should be considered as satisfactory operation of an oil circuit breaker. The opinions vary so much that we hesitate to recommend a definition and would therefore suggest that the satisfactory operation would mean the rupturing of current within a definite time limit after the energizing of the trip coil, which time allowance could be relied upon for selective operation of relays on the system, without throwing burning oil outside of the tank or causing permanent deformation of tanks or any of the current-carrying parts.

It is suggested that the rating be made with only the manufacturer's factor of safety to cover any inequalities of materials and manufacturing processes so the purchaser of an oil circuit breaker could then rely on a given rating at all times and should not count on more.

Very few data were given which would show the relation of the constants (reactance and resistance) of the circuit as affecting the interrupting capacity of the breaker, although some tests made by one of of the operating companies showed that reactance imposed a heavier duty on the oil circuit breaker than resistance for the same value of current.

In several cases reported, the increase in the speed of operation of some of the older type breakers has made an improvement in the interrupting capacity.

Ninety per cent of the cases reported have found venting the tanks desirable.

There is no universal standard for oil to be used in circuit breakers, although some companies have interchangeably used oil of one manufacture in breakers of another. It would be desirable if some standards could be adopted by the oil circuit breaker manufacturers so as to reduce the number of types of oil required for stock with companies having several makes of breakers.

CORRESPONDENCE

INPUT RESISTANCE OF THERMIONIC TUBE

To the Editor:

In the January issue of the JOURNAL, there appeared an article by F. C. Blake entitled "On Electrostatic Transformers and Coupling Coefficients." On page 28 of this article occurs the following sentence: "Van der Pol's experiments seem to call in question the statement made by Miller that the input resistance of a thermionic tube is always positive for a capacity load, for Van der Pol with such a load actually had the tube working as an oscillation generator." In a footnote, Mr. Blake refers to my Scientific Paper No. 351 of the Bureau of Standards.

In view of the facts that the statement which occurs in my paper is of considerable fundamental importance in vacuum tube theory, that it is based upon mathematical theory which has been checked by a number of others and that I have also checked my theoretical results very carefully by measurements, many of which are described in my paper; it does not seem advisable to pass over a casual questioning of the validity of my results.

I have examined Dr. Van der Pol's paper in *Phil. Mag.* 38, p. 90, 1919, and do not find anything other than results which support my conclusions rather than render them questionable. In the experiments outlined therein, the plate circuit of the tube contained a circular wire 60 cm. in length in series with a condenser having plates 10 cm. in diameter, the capacity of which could be varied by varying the distance between the plates. With the plates separated a few centimeters oscillations were not obtained, but when the distance was reduced to about one centimeter, oscillations were set up. The load in the plate circuit of the tube, therefore, consisted of an inductive reactance and capacity reactance in series and as should be the case, a reduction in the capacity resistance led to the generation of oscillations. In the oscillating condition and assuming coupling only through the tube capacities, the load in the plate circuit must have been inductive. This can be checked by a rough calculation using the data given by Van der Pol. The capacity of the condenser with a plate separation of one cm. was about 10 micro micro-farads, the circular wire, if of No. 16 gage or smaller, would have an inductance of 0.6 microhenry or more. The wave length of the oscillations was 3.75 meters corresponding to a frequency of 80 million. Under these conditions the inductive reactance was +300 ohms, the capacity reactance −200 ohms and hence the net load was inductive.

The above facts do not substantiate the question raised by Mr. Blake as to the validity of my results.

JOHN M. MILLER

Permissible Operating Temperatures of Impregnated Paper Insulation in Which The Dielectric Stress is Low

BY D. W. ROPER

Superintendent of Street Department, Commonwealth Edison Co., Chicago

FOR a number of years the standard low-tension direct-current feeder cable in Chicago was 1,000,000-cir. mil two-conductor concentric paper-insulated cable with three pressure wires laid up with the outer conductor. Apparently there has been the greatest tendency to overload this particular size of cable more than any other as, with both single and concentric cables in service, it was difficult to make a proper distinction between the carrying capacity of the two kinds of cables. About ten years ago we had two cases in which the cables of this kind were called upon to carry loads somewhat larger than had been customary, and steadily throughout the day instead of a short peak in the evening. The two customers in these cases, in different portions of the city, were both manufacturing customers with an eight-hour load, and on account of some increase in business they increased their load on short notice when no cable was available for another feeder to their premises. In each case, the cable has to be ordered from the factory so that this unusual load was carried by these cables for some three or four months. In the first case of this kind we were so disturbed about the temperature that we made a rather extended series of temperature measurements, using one of the pressure wires imbedded in the outer conductor as a resistance, and determining the temperature by the rise in resistance. This, of course, would give us the temperature of the outer conductor which would be probably 8 or 10 deg. lower than the inner conductor. The temperature measured in this manner was slightly above 100 deg. cent., and as there was some doubt regarding the accuracy of the determination made in this manner, it was checked by cutting a small hole in the lead sheath of the cable and in the outer insulation, and measuring the temperature of the outer copper with a thermometer. The temperature taken in this way checked very closely with the temperature as determined by the rise in resistance of one of the pressure wires. The insulation removed in this manner was carefully preserved and compared with the insulation in a piece of new cable, and it was impossible, by careful examination, to discover any appreciable difference.

In the second case which occurred some months later, we were not so disturbed about the damage to the insulation, although the load carried per cable was approximately 10 per cent heavier than in the first case. The temperature measurements were on this account omitted. The line was carefully patrolled several times per week, however, in order to detect any symptoms of impending trouble and a number of minor mechanical defects in the lead sheath were discovered during the time that this cable was overloaded.

In each of the above mentioned cases the service over these cables was discontinued, a few years after the period of overload, due to the customers moving to another location. The cables were, therefore, removed, carefully examined, the insulation found to be in good condition and the cables reinstalled at another location.

Messrs. Clark & Shanklin in their paper on "High-Tension Single-Conductor Cable," presented before the Institute on June 24th, 1919[1], give some data for the radiation constants of conduits under average heating and hot-spot conditions. The authors of the paper advise that the figures for average heating were determined as the result of a large number of observations, and the carrying capacity obtained from these data appears to check fairly well with our experience with the sizes of cables under discussion. In later years 1,000,000 and the 1,500,000-cir. mil single-conductor cables have been our standard sizes for low-tension direct-current feeders. The carrying capacities of these several sizes of cable as determined from the Clark and Shanklin data for average conduit conditions and for a maximum copper temperature of 100 deg. cent. are as follows:

Size	Load per conductor Amperes
1,000,000-cir. mil single conductor	1110
1,500,000-cir. mil single conductor	1360
1,000,000-cir. mil concentric	790*

*Note: this figure is one-half the current for a 2,000,000-cir. mil single-conductor cable.

Our records indicate that a considerable percentage of all of our low-tension feeder cables will exceed these figures for a few hours each night during a month or two of the maximum load period in the winter.

The paper by R. W. Atkinson in the September, 1920 JOURNAL of the Institute gives the data for calculating temperatures of copper conductors in cables by an entirely different method. For the purpose of calculating the maximum temperature by the Atkinson method, the air temperature in an idle duct in the conduit in which the cables are installed and the load carried by the cable are necessary. During the past few months we have made a number of temperature surveys and have calculated maximum copper temper-

Presented at the 9th Midwinter Convention of the A. I. E. E., Feb. 16-18, 1921.

1. Vol. XXXVIII, p. 944.

atures by the Atkinson method, and have made curves of temperature over a number of consecutive days in some of our heavily loaded conduits. These curves show that the minimum temperature occurs Monday morning after the light loads on Saturday afternoon and Sunday, and further that there is a gradual increase in the maximum daily temperature from Monday until Friday. It is, therefore, a rather tedious job to discover from such tests and from our load records the total length of time during any given period that the copper temperature has exceeded any specified figure on any particular cable. The results obtained to date by this method indicate the maximum copper temperature of our low-tension feeder cables in the large and crowded conduits immediately adjacent to the substations is generally higher than 105 deg. cent., and in a number of locations considerably exceeds this figure for several hours per day for each of five days in the week during the winter months.

In one or two cases where, in the case of our older substations, we have 20 or 24-duct conduits leaving the substations with nearly all ducts occupied with loaded feeder cables, vacant duct temperatures of approximately 100 deg. cent., are found for a short time on Friday afternoon during two or three weeks in December. Such idle duct temperatures, together with the load readings, indicate by the Atkinson method a maximum temperature approaching 200 deg. cent. on the inner conductor of a concentric cable. One of the concentric cables in this conduit was removed and examined for the purpose of this investigation, and incidentally an opportunity was afforded to report on one item not scheduled. Upon removing this section of cable, a hole about one inch in diameter was found in the lead sheath about eight inches from the mouth of the duct. It had apparently been caused by the sheath catching on the edge of the duct when the cable was installed without being noticed by the workmen. In the immediate vicinity of this hole, the paper insulation is not only quite black but also quite brittle, so that it breaks very readily when handled. At another point thirty feet away, the paper insulation, while slightly darkened, is still well filled with compound, and pliable, although it has lost some of its strength. From the information secured from this sample of cable and from other samples secured from similar crowded conduits in the vicinity of large substations, I think that we may reasonably conclude that when the copper of one of the low-tension cables on our distribution system reaches a maximum temperature of 180 deg. it is being heated beyond a safe limit, and deterioration of the insulation will result; and further, that the deterioration will be greater if there are holes in the lead sheath at the point where such temperatures are reached.

During the past year in connection with changes on our distribution system, we have removed concentric cables from locations where records and subsequent examination into the conditions indicate that the maximum copper temperature must have materially exceeded 100 deg. cent., but the exact amount cannot be definitely stated. We do know, however, that in such cases the insulation has been found in good condition, so that the cables have been reinstalled and placed in service at a different location.

The time during which the maximum temperature is maintained has undoubtedly a considerable bearing on the subject. We know, for example, that the insulation next to the lead sheath of a new cable shows no sign whatever of damage by heating, although the lead is applied at a temperature which probably exceeds 300 deg. cent. We know, also, that when our cables are suddenly overheated because of a burn-out at a more remote point from the source of supply, that the insulation shows no indication whatever of damage, although the temperature of the copper must have considerably exceeded 100 deg. cent. for a short period. It is apparent, therefore, that not only due consideration should be given to the time during which the maximum temperature of the copper persists, but also that in an operating system it is not possible to determine the maximum safe limit exactly, as the temperatures are continually changing and it is not possible under working conditions to maintain any particular maximum temperature for any considerable time. Apparently the best that can be done is to determine the maximum temperature and also average curves showing the number of hours per year that temperatures near the maximum are maintained. From an examination of the insulation of cables corresponding to a number of such curves we should be able to establish, first: A lower limit at which the insulation will not be injured, even when the temperature is maintained for long periods of time; and second: An upper limit above which we know that the insulation will be injured if such temperature is maintained for any considerable time. From the information so far obtained in Chicago, the best that can be done is to place the lower limit at about 110 deg. cent. and the upper limit at about 180 deg. cent. It is recognized that these limits may be too widely separated to be of material value in the settlement of the question at issue, but it is hoped that as further investigations are made, additional information will be forthcoming which will serve to bring these limits within a narrower range.

The Story of the Induction Motor

BY B. G. LAMME

Chief Engineer, Westinghouse Electric & Mfg. Co.

This paper covers the history of the technical side of the development of the induction motor, principally as the author saw it. It indicates the various stages of development from the early Tesla motor, with polar field construction, to the distributed field construction, and from the early wound-rotor type to the later almost universal cage type. Reference is made to the development of the cage motor with high starting torque, and the reasons which led up to it. The early single-phase induction motor is also treated, indicating various stages in its development.

The latter part of the paper covers the growth of the motor as an industrial apparatus and its application to various unusual services, such as heavy mill work, locomotive operation, ship propulsion, etc. Speed control of such motors is also described.

The papers refers, principally, to American practise, although occasional reference is made to foreign work. The description covers, primarily, the development work of the company with which the writer is connected, and reference to the work of other companies is incidental, due, largely, to lack of sufficient inside data.

LOOKING back over the technical history of the induction motor, we see an apparatus which is of extreme theoretical interest, and, at the same time, is of inestimable practical value. It is impossible to define just what effect it has had upon the general development of the electrical industry. It is probably safe to say that without this motor the whole trend of the art would have been greatly modified; for unquestionably the induction motor has had a very great part in placing the polyphase alternating current system in its dominating position of today. Practically 95 per cent of the generated electric power of today is by alternating current. It is beyond belief that the a-c. system could have reached anything like this dominating position if there had been no induction motor for the utilization of alternating current for power purposes. The induction motor should, therefore, be considered as a fundamental element in the alternating current system as a whole.

Considering the importance of the induction motor, the writer has considered it to be of interest and value to record a history of its development as given in the following pages. It should be understood distinctly that this applies only to American development, and only insofar as has come within the writer's knowledge and experience. European countries, it should be understood, were not behind America in the development of the motor itself, and, in fact, in some ways Europe was a year or two ahead. The historical Lauffen-Frankfort experiment of 1891, where a relatively large induction motor was operated over a long transmission line, is a good example. The story of the European development would be a most interesting account in itself and, unless this is soon recorded, undoubtedly valuable parts of the early history of this work will be lost.

This story, as presented, covers principally those developments with which the writer has been in more or less personal contact through his connection with one of the large manufacturing organizations. If members of other organizations would record their part of the story, it would undoubtedly be of material benefit to future engineers. All manufacturers have had their troubles and their successes and their triumphs and discouragements, presumably pretty much as shown in this story. It is one of the greatest misfortunes of the engineering profession that so few of the great pioneers and the development engineers have recorded the steps which have led to success or failure. With such a record, a failure may be of just as much value as a success, for the art is built upon failures as well as successes.

The induction motor, in its early days known as the "Tesla motor", appeared in 1888. It is difficult to say just when it was invented. Tesla invented it without question. Professor Ferraris also invented it. Shallenberger was treading on its heels in his alternating-current motor-driven meter. Bradley was very close to it in his polyphase synchronous converter. Thomson was also close to it in his three-coil arc machine. All of these men were working independently of each other, so that it appears that the induction motor was bound to be invented sooner or later. However, to Tesla belongs the true credit of independent invention and of bringing the matter before the public in such a way as to lead eventually to practical results.

When the Tesla motor first came out, it was doubtful whether anyone had any real conception of its actions or its characteristics as we now see them. Tesla knew two things, namely that if a magnet was moved across a conducting surface or plate, it would tend to drag the plate with it, and that the action of such a moving magnet could be produced by out-of-phase alternating currents. These are very elementary conceptions, but, come to think of it, what more fundamental conception of the real operation of the induction motor can there be, than the above? The induction motor of today is simply the above action put in practical form. True, it is an immense jump from these early conceptions to the practical machine of today. The intermediate gap has required years and years of highest effort to span, and unquestionably some of the best analytical ability expended in the electrical field, has been on the induction motor problem The development of the induction motor being, in reality an analytical problem, it did not make much

To be presented at a joint meeting of the A. I. E. E. Sections in District No. 5, at Detroit, Mich., March 18, 1921.

headway in the "cut and try" days of 1888 and '89, when the Westinghouse Company was undertaking to put it into commercial form. Our only frequencies in those days were 133 and 125 cycles and the only alternating current supply circuits were single phase. None of these were suitable for the new motor and, therefore, it was badly handicapped at the start. In

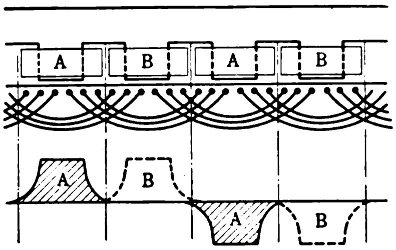

Fig. 1

fact, it was an almost hopeless proposition to bring it out commercially. However, the full extent of the handicap was not fully realized at the time and, therefore, a vast amount of development work was carried on with the idea of producing an operative device. Tesla worked on this development himself in 1888 and '89 assisted by Mr. C. F. Scott who later took charge of the development and made very important advances. Considering the lack of knowledge of magnetic problems and conditions of those days, it is really a source of surprise that Mr. Scott developed the motor as far as he did. He devloped the slotted secondary, with overlapping distributed winding, up to a quite effective point. Apparently he did not fully recognize the relations of secondary resistance to starting torque, nor did he know the inherent speed-torque characteristics of the machine, but neither did any one

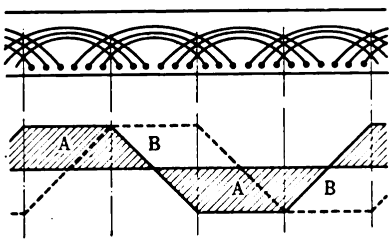

Fig. 2

else. In fact, a full working knowledge of the characteristics of the induction motor did not develop until some years later. However, Mr. Scott's work showed quite clearly that the motor required some materially lower frequency than any in existence at that time, but as such lower frequency and polyphase circuits were not yet in existence he was fighting a hopeless battle for the motor

These early Tesla motors, as developed by Mr. Scott, showed quite good operating characteristics and might have proved commercial with suitable supply circuits. In fact, some small installations for operating mining machines were made near Pittsburgh, which were successful from the motor standpoint. Yet the motors were fundamentally handicapped in one feature, namely, the primary flux distribution. In those days, distributed field or primary windings were unknown and only the simple polar types of magnetic construction were recognized. In consequence, these early induction motors were made with distinct polar projections, each projection carrying a primary or field winding, with alternate coils belonging to one phase of a two-phase circuit. The flux, therefore, of the adjacent poles or phases did not overlap each other as in the modern induction motor and uniform progression of the magnetic field, as we now understand it, was not possible. This early arrangement might be illustrated by Fig. 1. Obviously with such an arrangement, the magnetic field of one pole covered a relatively small percentage of the pole pitch, and one of the greatest steps forward, in motor design, was the recognition of the advantages of distributed overlapping primary windings. The difference may be illustrated by Fig. 2. Here it may

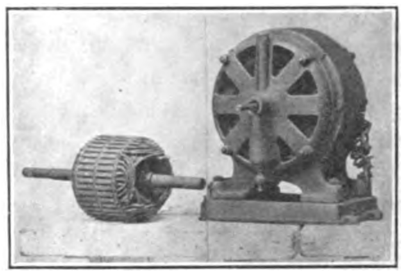

Fig. 3

be seen that the magnetic flux per pole covers practically the whole pole pitch as compared with one-third of the pitch in Fig. 1. Moreover the magnetic field can progress at a comparatively uniform rate and the resultant of two phases can give a magnetic field comparable with either one of the phases. Fundamentally, the more important feature in the distributed field winding is the large magnetic flux per pole compared with the former construction. This has a direct bearing upon the output characteristics of the machine. With the same expenditure in magnetizing current, an increase to two to three times the total flux means a revolutionary improvement in the characteristics of the machine in general.

When Mr. Scott dropped the work in 1890, primarily due to the handicap of unsuitable supply system, as mentioned before, but also due to financial stresses in the company's affairs, he had probably gotten out of the motor about all that was possible with the type and construction and knowledge at hand. As stated before, he had a distributed short circuited secondary winding adapted for averaging the torque conditions, although not of a type desirable for later machines; he had an odd or hunting tooth in the secondary to

lessen magnetic locking; he also tried the skewed secondary construction; he had a relatively small air gap; and he had a well laminated primary structure. In general appearance, the motor was not unlike some of the induction motors of today, see Fig. 3. This was a prideworthy result, considering that it was developed largely by "cut and try" methods.

In 1890, this induction motor development as a whole, was dropped by the Westinghouse company and was not taken up again actively for about two years, although some slight experimental work was carried on meanwhile.

During 1890 and '91, slotted type armatures for railway motors and direct-current generators were developed by the Westinghouse company to supersede the older surface-wound types. In carrying out this work, the writer considered the use of similar types of windings for alternating-current machinery and even built a slotted type single-phase alternator armature, as early as 1891, this having a large number of slots per pole. These developments led to the consideration of the use of a direct-current type of slotted armature winding for generation of *polyphase* alternating current and it was recognized that the mere addition of polyphase collector rings to the armature winding of a direct current machine would allow it to be operated as a polyphase alternator. This was principally in connection with the possibilities of building synchronous converters. This work also led to the consideration of similar types of windings on induction motors. This led the writer to take up the induction motor problem, in his idle moments, and in working out the idea of a distributed polyphase winding of the above type, he realized that the magnetic conditions set up by such a winding would be far superior to those of the early Tesla motors. He explained this matter to Mr. C. F. Scott, who was very much interested, and it was then suggested that the writer take up this work, at the first opportunity, with a view to building such a motor. Mr. Albert Schmid, then superintendent of the company, was also so much interested that he soon authorized building such a motor experimentally This was undertaken about 1891. The induction motor situation looked more promising at that time, for in 1890, it had been decided, after careful consideration, that a new standard frequency, much lower than 133 cycles, should be adopted by the Westinghouse company. Mr. L. B. Stillwell, who was giving this matter active attention, finally, after considering all sides of the question, recommended in favor of 60 cycles, and, in 1891, this was making some progress. This, therefore, indicated that one handicap on the induction motor would soon be removed. It is true that polyphase circuits had not yet come, but we were hopeful in those days that this would be one of the next advances.

This first motor with distributed windings, was tested in 1892. This motor had both distributed primary and secondary windings, with a number of secondary slots prime to the field slots. The secondary winding was of a polyphase type, short-circuited on itself at the polyphase terminals. The stator was the primary and the rotor was the secondary. In fact, this motor resembled very much the modern induction motor.

On test, this motor gave very surprising results, compared with anything which had gone before. Its pull-out torque was very large and its starting torque was very much better than expected. In fact, we felt that we had here practically a commercial motor. The interesting feature was that the current capacity of this motor was materially larger than anticipated, probably due to the effect of the distributed winding in dissipating the heat. Taken all in all, this motor was most satisfactory in showing that very good induction motors could be built when the proper time came.

An interesting test in connection with this motor was in determining the effect of short-circuiting the secondary winding from coil to coil, instead of the usual polyphase terminals. In the final test, the insulation was scraped or burned off the end windings of the secondary, exposing the bare copper, and the ends were then thoroughly soldered together, thus making a continuous ring of metal at each end. In other words, this was practically a modern type of cage winding. On test, this showed even better results than before and proved conclusively that short-circuiting of all the end windings together was, if anything, much better than simply short circuiting the groups of windings on each other. In other words, this was an early proof that the cage type secondary was a most effective type where the starting conditions would permit. However, the cage type secondary had been tried in Europe at a still earlier date.

For a year or so, the induction motor development lagged due principally to the fact that there were yet no supply systems. In the latter part of 1892, however, the Westinghouse company prepared designs for a large induction motor to be used in connection with the World's Fair exhibit at Chicago in the following year. This motor was actually built and put on exhibition and a description may be of interest as it was apparently the first quite large induction motor put in operation in this country.

The World's Fair lighting system, as laid out and installed, was 60 cycles, single phase, 2200 volt. However, in the early stages of the development of the lighting machinery, Mr. Westinghouse suggested that this would be a good opportunity to illustrate the possibilities of the polyphase system, and, therefore, he proposed that the generating units, of 1000 h. p. each, be made with double fields and armatures, that is with two 500 h. p. machines side by side on the same shaft, but with the single-phase armature windings of the two units displaced 90 deg. from each other. His idea was that the general lighting of the exposition would be from single-phase circuits, as was the usual

practise in those days, but by bringing two out-of-phase circuits to the same locality, polyphase current would be available for operating polyphase apparatus. This arrangement was adopted and, therefore, this Chicago exposition represented the first large installation of polyphase generating machinery in this country.

On account of the availability of polyphase current, a special polyphase exhibit was then devised for the Electricity Building at the Fair. In this exhibit was a 300-h. p., two-phase 220-volt induction motor, to be operated from the polyphase lighting circuits. This motor in turn was belted to a 500-h. p. a-c.-d-c., 30-*cycle*, generator for delivering 550 volts direct current and approximately 390 volts, two-phase, from its collector rings. The low-frequency current from the a-c. side of this a-c. - d-c. generator was then carried, through step-up and step-down transformers, to the collector rings of a machine of corresponding size, used as a synchronous converter, to deliver direct current at about 550 volts. This synchronous converter was started by means of an auto-transformer on the a-c. side, with five voltage steps. In addition, a synchronous converter of about 50 to 60 h. p., giving about 60 volts d-c., was also operated. It can thus be seen that this was a true polyphase exhibit and it was very much ahead of its time, as neither induction motors nor synchronous converters were yet on the market. Moreover, the 300-h. p. induction motor was apparently far ahead of anything yet built, in regard to capacity. This motor had a rotating primary with stationary secondary. It had twelve poles and the distributed primary winding was of cable threaded through partially closed slots, this construction being adopted in order to decrease the primary magnetizing current, thus indicating that even at that early day this feature was quite fully appreciated. The stationary secondary also had partially closed slots with one conductor per slot, these conductors being connected to give two secondary circuit 90 deg. apart. When the motor reached full speed the secondary circuits were short-circuited, but during starting they were closed through a series of long heavy carbon rods, placed in a basement beneath the exhibit, these rods being used for starting resistance. Not much was known about starting resistances in those days, and, as this carbon starting outfit would sometimes get red hot while the motor was being brought up to speed, it was not considered desirable to let the public see it. However, the arrangement was quite effective and, although crude, nobody knew anything better. This exhibit was started about the first of July, 1893, being late in delivery due to the many new features involved. When this exhibit was first started it created quite a commotion, as many of the neighboring exhibitors had concluded that the apparatus was never intended to run. It made enough noise to attract an undue share of attention and, therefore, was quite successful as an exhibit. The writer was present during the starting and the first few days of operation of this exhibit and noted many amusing incidents. For instance, one morning he observed a very intelligent looking man staring quite intently at the large induction motor. Upon being asked if he wanted to know something about it, the man said that he wanted to know what kind of a machine that was. Upon being told that it was an induction motor of 300 h. p. capacity, he blurted—"My Lord! I didn't know they made them that big." He then explained that he was a college professor from a southern university, and was quite interested in induction motors, but thought that they were built mainly on paper and didn't know that induction motors had been made which would run and carry loads. This is an instance of the kind of attention the apparatus attracted.

Something should be said here concerning other polyphase exhibits at the Chicago Fair. The A. E. G., of Berlin, had an exhibit right across an aisle from the Westinghouse. . This exhibit while much smaller and less pretentious than the Westinghouse, was quite interesting as it contained a small polyphase generator, of about 100 kw. capacity, and an induction motor of about 75 h. p. This exhibit was in the charge of a young engineer who was apparently concerned simply with technical matters, while the daily operation was in the charge of an older man. A few minutes after the writer first called at the Westinghouse exhibit, he was informed of the A. E. G. exhibit across the aisle and immediately visited it. Upon examining the A. E. G. generator and noting its *distributed* armature winding, he asked the young engineer who was present, how the regulating characteristics of the distributed armature winding compared with those of the toothed type. The German engineer looked at him and replied—"Ah, you are from the Westinghouse company", and he volunteered nothing further. An interesting thing about this A. E. G. induction motor was the use of a water rheostat in the secondary, for starting purposes. One evening when the jury on electrical awards visited the A. E. G. exhibit for inspection and report, the motor was started and a fire resulted in the starting apparatus, which created excitement and brought the fire engines. It was found that the water rheostat had caught fire, which fact in itself was considered quite a joke among the Westinghouse engineers. This A. E. G. exhibit was interesting in showing that Europeans and Americans were independently developing polyphase apparatus along very similar lines.

In the Schuckert exhibit, also in the Electricity Building, there was a polyphase induction motor of small capacity with distributed windings. This, however, was not operated as there was no suitable supply circuit.

If the writer remembers rightly, the General Electric Company also had certain polyphase apparatus on exhibition. A synchronous converter of about 75

h. p. capacity was shown. However, no polyphase apparatus in operation was observed.

It was in 1893 that the induction motor business in this country really got into motion. It was about this time that the question was taken up, in a conference in the Westinghouse company, as to how to get this motor on the market. After various plans had been discussed, the suggestion was advanced by the writer

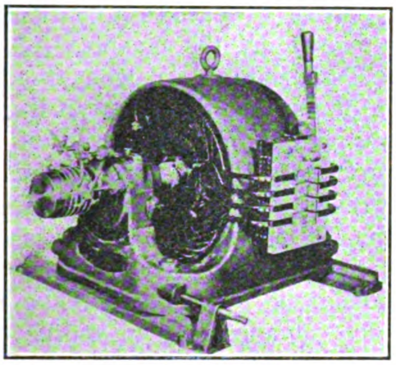

FIG. 4

that if we would make a "fad" of polyphase generators, so that everybody would buy them, the motor question would soon settle itself. This suggestion apparently was considered a good one, for instructions were given immediately to get out a standard line of polyphase generators and push them on any and every occasion. This was done and it was remarkable how quickly the public actually took to the polyphase generator. It became a real fad and soon developed into standard practise. The development of a standard line of induction motors

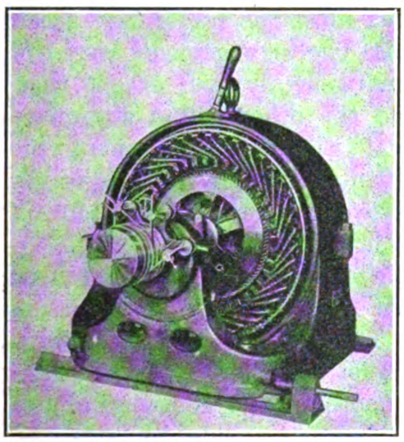

FIG. 5

was also authorized, and, to illustrate how quickly the commercial demand came, it may be said that customers' orders were taken for the motor quite a long time before any of them were ready for the market. In consequence, we had to rush the first line of motors on the market, even before we had much chance to do any development or experimental work. In fact, most of the experimental data had to be obtained from motors on customers' orders. However, this was common practise on most machinery in those days, and we got our data piecemeal, from several orders, rather than from complete tests on any one piece of apparatus. This first line of motors was for 60 cycles. Work was started on it sometime in 1893, and in 1894 motors were being completed for the market.

These first Westinghouse commercial motors, were of the rotating primary type with stationary secondaries. This construction was largely because the secondaries of these early motors were made with a number of comparatively large bar conductors with correspondingly low voltage and heavy current. As starting resistance was used, this meant that the problem of handling the current by collector rings and brushes was a quite serious one, and, therefore, by placing the secondary winding on the stationary element and the primary on the rotor, the collector ring and brush problems were much simplified. The primary winding was always of considerably higher voltage, with comparatively small currents which thus could be handled much more easily.

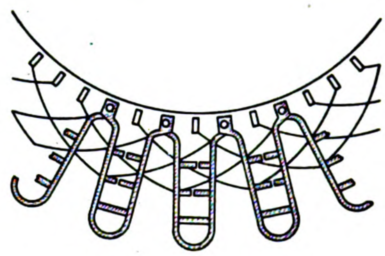

FIG. 6

On these first motors, "closed-coil" two-circuit types of secondary windings were used, with four leads carried out to a pair of switches on the frame of the machine. A cast iron resistance grid was connected permanently across each phase and the switches simply short circuited these grids after speed was attained. This was a relatively crude arrangement, but simplified the problem of putting these early motors on the market. We would make these iron grids with "bridges" in them and on test we would simply saw out bridges until we got the desired starting characteristics.

On one of these early motors the writer made some tests to determine whether two-phase short-circuiting of the secondary winding gave as effective results as three-phase. He brought out leads from the stationary winding to make a number of combinations and he made a very interesting discovery. It was found that when the closed coil winding was short-circuited at three points, representing three-phase, a certain pull-out torque was developed. Short circuiting at four points, representing the socalled two-phase, but in reality four-phase, a higher pull-out torque was developed. Short circuiting at six points, a still higher torque was developed and at eight points,

etc., up to twelve, there was improvement. Beyond twelve points short-circuited there appeared to be but little gain. Furthermore, it was noted that the operating characteristics of the motor as a whole were considerably improved with more short circuits. This further verified earlier conclusions that from the running standpoint a complete cage winding was the most effective type. This then led to the development of an improved secondary winding which combined resistance starting with the effects of a cage winding at full speed. A closed-coil, two-circuit or "series" type of winding, of low voltage, was used in the secondary, with a large number of iron grids connected *between adjacent coils*, sufficient in number to span, all told, practically one pole pitch of the secondary winding, see Fig. 6. This gave very effective starting conditions. As full speed was attained, a short circuiting ring, surrounding the secondary winding, was shifted circumferentially to bring it into contact with the secondary bar end connectors at a large number of points, thus changing the winding virtually to a cage type,

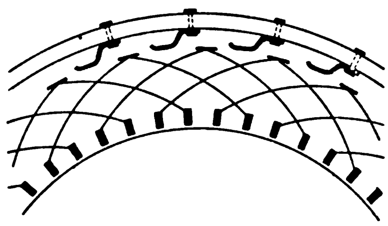

FIG. 7

Fig. 7. Thus the advantages of resistance starting and cage running were obtained. This was designated as the type B motor to distinguish it from the earlier motors gotten out by the Westinghouse company. The above construction was quite effective and motors of this type gotten out at this time and during the next year or so, are still in operation. This motor was so successful that a number of Westinghouse people said it was no use trying to beat it, as it was too near perfection. However, it was unduly expensive in construction and had certain inherent limitations which promised eventually to be troublesome. The rotating primary was all right for 200 and 400 volts, but for materially higher voltages, which showed promise of coming, it did not look so well. Also at this time, motors of one h. p. and smaller were being built with stationary primaries and with rotating cage type secondaries, and these indicated possibilities which were well worth following up.

It should be stated also that about the same time that the Westinghouse polyphase development opened up, a corresponding development took place in the General Electric Company and it began to put out polyphase motors with distributed primaries. Apparently this development was entirely independent of the Westinghouse company and arose primarily from analysis of the true conditions required for a successful induction motor. However, on account of the patent situation, the General Electric Company soon brought out what was called the "monocyclic system", with a view to avoiding the Tesla patents This was really a form of unbalanced polyphase system, in that it had one main phase and one auxiliary or "teaser" circuit for furnishing, principally, magnetizing current to the motor. The energy supplied to the motor was largely single-phase, but the magnetization was polyphase, at least to a considerable extent. This was supposed, by the inventors of the system, to avoid the Tesla patent, but when one looks at the problem from the present viewpoint, it is quite evident that this was simply a special case of the general polyphase problem. The General Electric Company developed excellent motors to operate with this monocyclic system. In fact, it was almost a case of necessity to use good motors with such a system, and, therefore, the monocyclic system may have been partly responsible for advancement in motor designs and construction. A motor which would work well on the monocyclic system would work extra well on a balanced system. One of the leading types of motors gotten out by the General Electric Company, either in this period, or at least quite early, was one of a rotating secondary type, with low resistance secondary windings, with iron or alloy grid resistance inside the rotor connected permanently to the windings, and with a mechanical means for short circuiting such resistance after the motor had accelerated to a certain point. In the Westinghouse type B motor, as already described, grid resistances were permanently connected to the low resistance secondary winding with provision for mechanically short-circuiting the windings at a number of points after the motor had accelerated. Obviously, these two arrangements were very similar in principle and general type, except that one had a rotating and the other had a stationary secondary. The General Electric arrangement presented one distinct advantage in having a stationary primary, which has proved to be the preferred form for induction motor work in general.

The Stanley-Kelly Company also put on the market an induction motor which, it was assumed, did not infringe the Tesla patents, because it did not produce a rotating magnetic field in the usual sense. The primary in this motor, really consisted of two polar type single-phase primaries side by side, but with the two sets of poles displaced 90 deg., and excited by currents 90 deg. out of phase with each other. These two single-phase fields acted upon a common secondary core and winding. The pole tips were slotted and contained a special distributed type of damper winding for lessening the armature reactance.

Due to the fact that the two magnetic fields set up were assumed to be simply alternating in space and not rotating, it was believed that this Stanley-Kelly motor, therefore, did not possess the rotating field of

the Tesla motor, and thus avoided the patent. However, the chances are that any modern designer who would analyze this machine, would say at once that it was simply a special form of the Tesla motor and obeyed the general laws of such apparatus. These motors were put out in considerable quantities, during the 90's, and were built very largely for two-phase, as the structure was better adapted for this. If the writer remembers rightly, the Stanley-Kelly Company also put out some split phase motors, using condensers and reactances to get the desired phase relations. These attracted considerable attention at first, but eventually they dropped out of sight, as was the case with practically all induction motors using condensers for phase splitting. Apparently the inherent difficulties in the early condensers themselves were an undue handicap. Practically all companies which built induction motors tried, at some time, the condenser method of phase splitt ng. The General Electric Company tried this scheme on a relatively large scale. The Westinghouse Company tried the scheme experimentally to a considerable extent, but put out very few motors, principally because it did not have a sufficiently good condenser.

By 1895, the polyphase motor had become pretty firmly established as a commerical device and was making great progress. Except in very small sizes, resistance starting was used exclusively. The cage type secondary was well known, but was used only in connection with small motors or for small starting torque, as it was considered that this type of machine inherently had insufficient starting torque for heavy motor service. This notion was overthrown through a radical development which will be described later.

While the polyphase motor was being developed, the single-phase induction motor was also given much consideration. In fact, in the very early Tesla work, in 1888 and '89 when single-phase circuits of 133 cycles and 125 cycles were the only ones available, various attempts were made to construct single-phase motors, operated through phase-splitting devices. This was usually on a basis of two-phase circuits on the motors themselves with unequal reatcance in the two circuits. However, this did not prove successful even for fan motors.

It was discovered, quite early in the game, that the two-phase induction motor of the early Tesla type would operate quite well on single-phase by opening one phase after the motor was up to speed. It was also discovered that if the motor was at standstill it could be started up in either direction by giving it a little push at the pulley. Moreover, it was noted that with the secondary set in certain positions with respect to the primary, the motor would start itself, with current thrown on one primary phase only. It is thus evident that certain phenomena of the single-phase induction motor were recognized as early as 1888 and '89.

From 1890 to '94, the Westinghouse company built for commercial purposes, a number of single-phase synchronous motors which were used in connection with certain western mining power work. These single-phase synchronous motors were not capable of starting themselves and, therefore, the practise, was adopted of starting them by means of induction motors. The writer acquired considerable experience in this work and succeeded in making some fairly effective split-phase motors for starting the synchronous type machines. In one instance, he took an early experimental motor and placed a distributed primary winding on the stator element and used a high resistance bar winding on the rotor, this bar winding being tied together at the ends by *heavy high-resistance alloy rings.* In the first trials, the motor started and accelerated the load all right, thus proving that satisfactory torque conditions were obtainable, but as the secondary bars were soldered in slots in the end rings the solder all melted and came out. A metal wedge arrangement was then adopted, instead of solder, with a view to obtaining good joints by mechanical means. It was soon found, however, that unequal expansion of the secondary bars, in the early period of acceleration, was sufficient to cause relative movement between the bars and the end rings at the wedged joints. Eventually threaded holes were tapped into the bars and rings and set screws were used to maintain the joints. This appeared to be fairly effective and the motor was then operated a large number of times without apparent injury. The experience obtained with this cage type of secondary winding was of value in the later development of cage secondaries as will be described. This experimental starting motor was the writer's first real attempt at a commercial split-phase motor. Previous to this, old Tesla polar type experimental motors on hand had been adapted for this starting work, under Mr. Scott's direction. In this particular case, the writer incidentally made some suggestions to Mr. Scott about the possible advantages of a distributed type of primary winding, such as we were working upon experimentally, and he accepted the suggestion so gratefully, that he immediately turned over to the writer the job of producing a starting motor, with the hope that he would produce something materially better than the former type. An interesting comment on this development, is that the customer's operators reported later that this new starting motor was by far the best one that we had yet put out.

In this earlier period, single-phase operation of the induction motor was thus fairly well understood, but it was only in infrequent and special cases that such method of operation was practised commercially. There had been a few cases where small exciters had been operated by single-phase induction motors, and such motors had been used for starting synchronous motors as described. However, it was not generally believed that the single-phase induction motor offered great promise commercially.

Later, however, there were occasional calls for special single-phase or split-phase induction motors, for various purposes. Some of these were so special that manufacturers did not think it worth while to undertake them. In other cases these special machines were built simply because they carried with them other business of a very desirable nature but which was not special. Apparently this was the experience of all manufacturers. In one particular case, which the writer calls to mind, a 25-h. p. high-frequency single-phase motor was wanted for some foreign installation. As the contract included a great deal of other apparatus it was agreed to build this motor.

The writer undertook to build this machine, using a standard polyphase frame and winding, with a special wound-secondary with collector rings, so that resistance could be used during starting. Phase displacement in the primary was obtained by means of reactance in series with one of the primary windings. On preliminary test this motor was most discouraging, as it barely pulled its rated load. Little improvements were then made here and there which helped it out somewhat. However, its overload capacity was relatively small and the machine seemed to be very sensitive at high torques. Its power factor was considered unduly low. However, after several months of effort, it was agreed to send the machine to the customer to meet his immediate needs, with the intent of taking more time and building a better machine for him. The motor accordingly was shipped, and work was begun on the designs for a new more powerful motor. However, before this got into manufacture, word was received from the customer that the motor sent him was very satisfactory in every way. He stated that he had many single-phase motors in regular service, but that this motor was by far the best of all. This, of course, did not mean to us that our motor was in itself an extra good one, but it meant that the other motors which he had must have been pretty poor, from our viewpoint. Possibly we had set our standard too high.

Even before the induction motor was invented, commutator-type single-phase alternating motors had been built and experimented with. The principles of both the series and the so-called "Repulsion Motor" were known back in the latter '80s, and it was also known that they could develop relatively high torques at standstill. Such motors, however, did not have the constant-speed characteristics of the induction motor.

As has already been mentioned, it was discovered in the early years of the polyphase induction motor that it would operate in either direction on single-phase, provided it was once started and brought up to speed, or even brought up part way. In other words its accelerating torque was zero at standstill and increased rapidly with increase in speed. On the other hand, it was known also that the series motor, in its various forms, had just the opposite characteristics, namely, it could develop an accelerating torque which was high at start, but decreased rapidly with speed. It was recognized quite clearly that a combination of these two characteristics would be very desirable for single-phase induction motor work. Prof. E. E. Arnold, of Karlsruhe, combined these properties in his type of motor, this type later being taken up by the Wagner company in this country. In this Arnold motor, the secondary or rotor was in the form of a direct-current armature with commutator and brushes, the brushes being short-circuited on themselves and set in such position with respect to the primary or field as to give the usual repulsion motor characteristics. When sufficient speed was attained, the armature would automatically short-circuit itself at a number of points, thus becoming the usual induction type of secondary. This type, the writer believes, was first put out in this country by the Wagner company, but since the expiration of the fundamental patents it has been built in various forms by many other companies.

In 1892, the writer accomplished experimentally very much the same results in connection with tests on an early synchronous converter. This converter was constructed from a direct-current railway generator, by adding a set of polyphase collector rings over the commutator, leaving part of the commutator exposed, so that direct current brushes could be used when the machine was operated as a converter. Among the various tests made on this machine, was one of self starting by connecting the armature and the series field of the machine in series and bringing it up to speed on alternating current, as a single-phase series motor. When full speed was attained the supply circuit was switched over to the collector rings and the machine operated synchronously with the line. This is simply an early illustration of starting by single-phase alternating current, by means of a commutator and shows that this general principle was well recognized even as early as 1892.

Eventually, various forms of commutator type induction motors were gotten out by different companies. A special type was built by the Westinghouse company but was not marketed, although a number of machines were developed. This consisted of a four-pole-eight-pole primary winding and an eight-pole parallel-wound direct-current type armature winding, with equalizer connections connecting points of equal potential on the armature. The machine was started on the eight-pole combination, with the armature and field in series and when it came up to speed, the field was switched, by means of a centrifugal device, from eight poles to four poles, and the armature automatically became a short circuited four-pole secondary, by means of the eight-pole equalizing connections. This type of motor operated quite satisfactorily on test, and the writer believed it could be made a commerical success. Certain objections were raised against it, such as relatively high first cost (which proved to be unfounded), and

the fact that *the brushes were not lifted from the commutator during normal operations.* This lifting of the brushes was claimed to be an absolute necessity, on alternating-current motors, regardless of the fact that on direct current machines the brushes remained on the commutator at all times. An interesting comment on the above is that recent practise on alternating commutator type induction motors has tended toward allowing the brushes to remain on the commutator. An inherent objection to the machine as constructed, was that it was of the *series* type during starting, and, therefore, was limited to voltages not exceeding 220. However, this type of machine could have been designed and used as a repulsion type, and thus would have been as adaptable for various voltages as any other commutator type induction motor. One advantage of this type was that no mechanical short circuiting device was needed on the armature.

Another type of single phase induction motor with commutator, which was brought out at a later period by the General Electric Company, is known as the repulsion-induction motor. This has a polyphase brush system, instead of single-phase on the secondary. This type of induction motor has been used to a very considerable extent in small sizes. It has no automatic short-circuiting device in its secondary, the circuits being closed through the commutator and the stationary brushes. In this motor the secondary current is commutated at all times unlike the preceding types, which have been described. Practically all these motors, except the Arnold type, belong to a much later period.

The induction motor had received very much study both in Europe and America, and many of the phenomena which are now the usual accepted knowledge, were first described in those early days. For instance, M. Leblanc in France had described and patented the use of resistance in the secondary for increasing the starting torque. Both European and American engineers had also discovered that an induction motor operated on polyphase primary, but with single-phase secondary would run at half speed. Also it was discovered, both in Europe and America, that cascade operation of two induction motors would give the equivalent of an increased number of poles, that is, a lower speed. The writer, with a view to making a polyphase railway equipment, designed and built a pair of two-pole, 25-cycle motors, in 1895, in order to obtain both cascade and multiple operation, for obtaining both half and full speeds. These motors were put on test and operated quite satisfactorily in cascade, and many interesting results were obtained. However, the work was carried no further on account of apparent limitations of polyphase trolley systems.

In the period between 1894 and '98, many odd "stunts" were tried with induction motors. In the literature of that time suggestions appeared, from time to time, regarding various possibilities or experiments and we were always inclined to check them up at the first opportunity. For instance, the half-speed operation obtained by operating the secondary on single phase was tried out, based upon a note which appeared in one of the European papers. The results, however, were not satisfactory due to the relatively poor power factor. Also, as early as 1894, attempts were made to obtain double speed by feeding the supply frequency to both the primary and secondary circuits of the motor. Double speed was actually obtained in this manner at no-load, but difficulty was encountered in attempting to carry any load and finally the test was abandoned.

In these early days it was also recognized that an induction motor, mechanically driven, could act as a frequency changer. The General Electric Company made some very early applications of this scheme.

Also in this early period, it was found that the induction motor would operate as a generator above synchronism. The first real experience of the writer. in this, was in 1894, when he was operating a 75-h. p. induction motor, driving a generator as a load. The motor was operated from a standard polyphase synchronous type generator which was motor driven. During these tests the driving power was purposely cut off the polyphase generator and it was observed that with the induction motor acting as a generator, and held at constant speed, the polyphase synchronous generator continued to operate, but as a synchronous motor, and at a somewhat lower speed than before. Measurements were then taken of the speed conditions and it was noted that when the synchronous generator was delivering full power to the motor, the motor had a speed of from two to three per cent lower than that of the generator; whereas, when the synchronous generator was disconnected from its power source and operated as a loaded motor, it ran at two or three per cent lower speed than the induction motor acting as a generator. This showed, therefore, that the induction motor was operative as a generator *above synchronism with its source of magnetizing current,* namely, the synchronous machine. It was known by the writer at even a considerably earlier date than this, that a synchronous motor could furnish "leading" or exciting current to its generator, and, therefore, it was obvious in this test that the synchronous generator, acting as a synchronous motor, was furnishing the necessary exciting current for the induction motor when the latter was operating as a generator. Quite elaborate tests were then made on this outfit primarily for the purpose of determining the general characteristics of a motor operated in this manner. This ability of the induction motor to act as a generator, was utilized experimentally shortly afterward, in connection with some electric hoisting apparatus which was being developed. The induction motor in these tests was used as a brake, when dropping the load, by operating it above synchronism.

The above illustrations are simply mentioned to

bring out the fact that many of the now well known actions of the induction motor were fairly well comprehended as early as 1894 and '95. In this earlier work there were two polyphase schools, so to speak, namely, the two-phase and the three-phase. The Westinghouse Company was known as the advocate of the two-phase polyphase systems, although it built both; whereas the General Electric Company was considered as favoring three-phase, although it also built both. The fundamental reason for the Westinghouse two-phase was principally in connection with lighting systems. When polyphase generators were first advocated strongly, for general purposes, practically all the service was lighting. With two phases it was considered that there was materially less complication in the smaller number, of feeders, than was the case with three phases, and this was true. It was recognized that the three-phase motor in itself was slightly better than the two phase, but it was felt that the disadvantage of the more complicated supply system considerably overbalanced the advantages in the three-phase motor and in the transmission. However, after a few years, conditions changed materially so that the needs of the polyphase transmission began to overbalance the advantages of two-phase distribution, so that there was a growing call for the three-phase system. It was about this time that the well known Scott two-phase-three-phase transformer system was devised, so that the advantages of the two phase and three phase systems could be combined. However, with the coming of true transmission systems and the further growth of the polyphase work, the three-phase system eventually dominated the market and the induction motor business became primarily three phase. This does not mean that the two phase system was a mistake, for it is probable, that, without this simpler system at the start, the polyphase system might have had more difficulty in making headway. It is simply one of the many illustrations in the electrical engineering field, where a simpler system, initially, has been driven out by a somewhat more complex system which contained greater possibilities in the end.

Nothing has been said yet regarding the 25-cycle frequency. This was inaugurated in 1893 in connection with the first Niagara Falls power installation and was quickly adopted, especially for synchronous converter work. The use of 25 cycles, however, did not have any controlling effect on the induction motor development in the earlier years, although it did have a bearing on certain of the later work, such as industrial plants and steel mill electrifications, as will be explained later.

By 1896, apparently the induction motor had settled down to fairly standard practise. As stated before, this practise covered the use of secondary resistance for starting except in the case of very small motors. The standard General Electric motor of this time was of the stationary primary type, while the standard Westinghouse had a rotating primary. Both motors were quite satisfactory machines, and, as mentioned before, there were people in the Westinghouse company who fully believed that the Westinghouse motor was 100 per cent perfect and could not be improved. However, the writer had his doubts. From time to time, as opportunity occurred, he had done considerable experimenting on cage type secondaries and was somewhat predisposed toward such a construction, provided the starting limitations could be overcome. This was one of the matters upon which he spent his spare time in analyzing and investigating, and finally as a result of his analysis of the characteristics of the motor, he saw a way to obtain the desired result. In those early days induction motors could be designed from calculations in a fairly satisfactory manner, and the effects of reactance, resistance, etc., upon the starting and pull-out torque were fairly well understood. Also crude methods were in existence for calculating the reactance. It was about 1895, while testing an experimental motor for hoisting purposes that the writer noted that, in this particular motor, very large starting torques were attained, although the motor had a pure cage winding in the secondary. Here was something worth following further, to find the fundamental reasons for this extremely good result. About this time the writer was working over the vector relations of the induction motor with a view to obtaining better methods of analysis and calculation. He found that by taking given motors and showing the various relations graphically, he could produce various points on the actual speed torque, current-torque and various other curves of the motor. This was a slow and laborious process, for a complete diagram had to be constructed for each point. After checking a number of machines and reproducing their characteristics, he then began to study special cases and among other things, he varied the reactance, *on paper*, over a wide range and found that if this could be reduced in a given machine, below a certain value, then not only good pull-out torques, but correspondingly good starting torques could be obtained *with permissible slips for constant speed work*. This was most interesting and several cases were checked up where unexpectedly high torques with cage windings had been found, especially in the case of some of the experimental motors already mentioned. The results showed that these were motors of small reactance, and they indicated, furthermore, that *sufficiently small reactance was actually obtainable in motors of commercial proportions with cage type windings*. This was most interesting as showing the possibilities for the development of a cage type motor for general power purposes. The writer then went into the analysis of reactance conditions most fully, and spent months partly in daytime, but mostly in the evenings, analyzing magnetic conditions, with a view to predetermining all the "leakages" or "stray fields", etc., and checking with existing machines. It developed, in time, that

he could reproduce, by calculation, the reactance conditions of practically all the existing machines. Also he took up the question of reducing the reactance fluxes to a point which would give relatively large starting torques with cage wound machines. In the early stages of this work he gave up the graphic method of solution, by transforming his diagram from graphics to a set of mathematical equations, derived directly from the geometry of the vector diagrams. With this set of equations he was able to produce quite quickly a complete set of characteristic curves of any motor. Also to obtain any desired starting and pull-out conditions, he could very quickly determine the limiting value of the reactance necessary. This work showed very definitely that it was entirely possible to produce a commercial line of polyphase induction motors with *pure cage type secondary windings with starting torques up to two or three times the rated torques* of the machines.

With these data available, it was decided to undertake to build commercial induction motors with cage secondaries. Motors of 20, 30 and 50 h. p. were first undertaken. All were brought through *from calculation* and all developed the expected starting torque conditions, namely, about two and one-half times the rated full-load torque and from three to three and one-half times pull-out torque. This was considered a most remarkable result at the time, as it had been generally held that cage motors could not develop, very high starting torques. In conjunction with this work, there was another fundamental departure from older practise, namely, in the use of voltage reducing transformers in connection with these motors. While these cage type motors could develop starting torques of from two to three times rated load, they also required starting or "line" currents of six to nine times full load current which was considered a prohibitive condition. Naturally the suggestion arose to reduce the starting current, and the starting torque proportionately, by the introduction of a small transformer at start, so that the motors would take not more than three times full-load current from the line when starting full-load torque, while at full speed they would be switched to the line voltage and would have the corresponding full-power characteristics. This was the origin of the auto-transformer or "compensator" method of starting.

Naturally the use of cage windings pointed directly to an inversion of type in the Westinghouse machines; that is, with the cage construction, the secondary or cage winding should naturally be placed on the rotor, in order to do away with all collector rings or other rotor connections, the stator winding being placed on the primary. These new motors were built in this manner and a few of them were put in service in 1896, in order to obtain some practical experience. Steps were taken immediately to carry the development below 20 h. p., in order to have a reasonably complete line. This line was gotten out in fairly complete shape in 1897 and was pushed actively during that year. At first this type of motor was received with a good deal of doubt, especially by technical people. Operators, however, especially in industrial plants, took to this type of motor on account of its substantial simplicity, and, in spite of many criticisms, they bought more and more of such motors until, in a short time, evidence began to show that this type was liable to take possession of the field. In fact many users of this motor would consider no other type. This line of cage-type motors was known as the Westinghouse type *C*. When first put out, it was criticised as containing a most palpable absurdity in the fact that no cage type motor could develop high starting torques, and yet here was a cage type motor with a reducing transformer for lessening the torque at start. What could be more absurd? A not uncommon statement at that time, in referring to the inadequacy of any kind of electrical apparatus, was—"It is as bad as the Westinghouse type *C* motor."

However, in time certain people awakened to the fact that this motor was able to develop the necessary starting torque, for the customers were thoroughly well pleased with it, and here and there it was used in places where the starting conditions were known to be very severe and yet it met these conditions quite satisfactorily.

However, while the real development in the cage-wound motor came as above indicated, yet there are numerous evidences of earlier work having the cage type of construction in mind. For instance, among the writer's specifications is one dated May 16, 1893, calling for an induction motor with a solid cast iron rotor core with 48 slots, and with the winding of "poured-in" copper, forming a complete copper cage.

Also as described before, in connection with a single phase motor for starting a synchronous motor, various types of secondary construction had been attempted. In building the high-torque type *C* motor described above, the secondary was first made with a simple bolted construction for attaching the secondary bars to the end rings. However, in the first 50 h. p. motor brought through, very severe starting tests were made, the motor being repeatedly started from rest under heavy torque, during many hours. At the end of this test it was noted that the per cent slip for large torques had increased considerably. The bolted secondary construction was then examined, and it was found to be defective in that expansion of the copper bars and end rings, due to changes in temperature, had actually stretched many of the bolts until the contacts were loose, and in some cases the bolts were broken. This looked like a most serious defect. However, one of the testing engineers, Mr. R. S. Masson, then made the suggestion that this trouble might be overcome by using heavy spring washers under the bolts, simply to take care of expansion and thus maintain good contact of the bars with the rings, regardless of tem-

perature. This was immediately tried, and the former test repeated, which resulted in no loose or broken bolts. This construction was then adopted as standard practise and was used for many years. However, it was difficult to get the manufacturing departments to understand the function of these spring washers, being prone to believe that they were purely to keep the nuts from turning loose.

Other companies also found it necessary to adopt this spring washer construction for maintaining good contact. This construction eventually went out of use in favor of cheaper types and not through operating defects in the bolted construction itself.

This cage type construction soon led to some very interesting developments and it was found necessary to obtain quite definite resistances in the secondary winding for giving the required torque, current and speed conditions. In consequence, as the secondary bars themselves were usually of copper, it was found necessary to vary the resistance of the end rings by using various alloys. Iron was tried, both cast and wrought, but usually with harmful results. Various bronzes, brasses, etc., were also tried, and in time quite a choice of materials became available for end rings. Moreover, it became usual practise to vary the resistance of the end rings of individual motors by slotting one or both of the rings radially to a certain depth, thus virtually lengthening the current path. This apparently did no harm and was quite effective in increasing the resistance of the rings, a range of possibly 100 per cent or more in resistance being obtainable in this manner.

This type *C* motor was not quite as efficient as later types, but it was of such sturdy construction and has such a high thermal capacity, compared with former constructions, that it obtained an almost undesirably good reputation in some ways. For instance in service, it could be pulled to standstill momentarily by a heavy overload and upon removal of the load, would immediately recover to full speed with no apparent injury, except in extreme cases. This was because the motor at standstill, on full voltage, had a starting and accelerating torque of two or three times the rated load. On account of these interesting, and, at that time, unusual properties, many people obtained an exaggerated notion of the motor's capabilities. For example, some of the Westinghouse people wanted to advertise that the type *C* motor could not be burned out, based upon certain experiences of the above nature. The writer, however, warned repeatedly that this was not a fact, but that the motor could be burned out just as surely as any other type of machine *if overloaded for a sufficient length of time.* He insisted that this motor, while a very good one, could not accomplish the impossible and that any claims that the motor could be overloaded to any extent without injury were dangerous and liable to react upon the manufacturer sooner or later.

These type *C* motors, in some cases, had pull-out torques of four times their rated capacity, and starting torques of three times their normal running torques. In consequence, due to the general shape of the speed torque curve, a sudden application of very heavy load would not easily jerk them out of step, so to speak, as was the case with the earlier types. In many of the motors of that time, a drop in speed of ten to fifteen per cent, due to sudden heavy overload, would bring the motor down to a decreasing torque so that it would very quickly pull down to rest. This condition is illustrated by Fig. 8.

Partly on account of the shape of the speed torque curve and partly due to the great thermal capacity of the type *C* motor, it acquired a reputation for sturdiness, reliability and capacity, held by no other motor before or since. This was a very good thing in those early times, when this type of motor was establishing itself, but in later years it has been recognized that some of these characteristics can be partly sacrificed to advantage, in order to favor other characteristics, such as efficiency, power factor, reduced dimensions, etc. In consequence, while the general characteristics of the type *C* motor have been retained to a greater or less extent in all general purpose cage motors of later times, yet a compromise has been made between the various characteristics, in order to give the most satisfactory all around results, with our later more accurate applications of motors to their service.

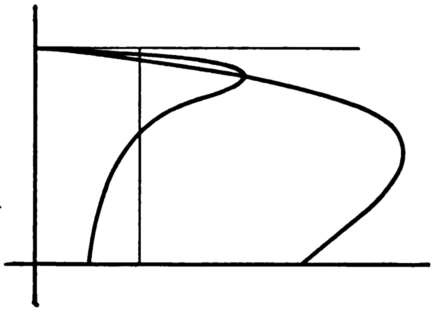

Fig. 8

It was not long after the cage-wound motor was put on the market until rare instances were noted where the motor, when used where speed reversal was necessary, would not reverse, but would continue to run in the same direction as before, (but at a much lower speed) when the primary terminals were reversed. The reason for this was not understood at the time, but investigation showed that, in each case of this sort, both in numerous shop tests and in outside instances, the relative resistance of the secondary end rings, compared with the secondary bars, was low. As a direct result of this, the end rings of such motors were slotted to increase their resistance compared with the bars; and in every case where this was done the motor would then reverse in a satisfactory manner.

This effect was noted as early as 1897 and '98 and is now recognized as due to the well known "cusps" in the speed torque curves of such motors, as shown in Fig. 9, but, at that time, the whole matter was more or less of a mystery. The writer recalls that in 1900 a prominent European engineer mentioned to him that the A. E. G., of Berlin, had claimed to have encountered cases where induction motors failed to reverse, but he said that he believed it to be theoretically and practically impossible. He was then informed that we had encountered similar difficulty in a number of cases and that there was no question about it,—it could happen. It was also explained to him that all cases of this sort, which we had investigated, were of the cage type and the relative resistance of the end rings in such cases was considerably less than that of the bars, the trouble being corrected by increasing the end ring resistance. He then remarked that as we said so he believed it, but he did not understand how it could be.

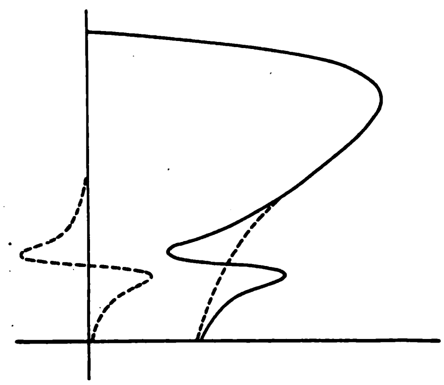

Fig. 9

In the analysis of the magnetic conditions, leading up to the development of the cage type of motor, as already described, the writer did much work in, plotting and analyzing the flux distributions and obtaining the magnetic "field forms" in the induction motor, during the cyclic changes. He investigated the effect of "chorded" or fractional-pitch windings and found their influence upon the magnetic distributions, reactances, etc. and incorporated expressions in his formulas for covering such windings. He determined that more uniform magnetic fields could be obtained by the use of such windings and that the most uniform effect was obtained when the span of the coils was shortened by an amount corresponding to half the width of one phase belt. Also the advantage of chorded winding, in giving the equivalent of a fractional number of wires per coil or slot, was worked out at that time and this feature has been used since to a very great extent.

The use of a fractional-pitch winding had been proposed and patented by the writer, in connection with commutation of direct-current machines, but in this the function of the chording was to reduce the reactance of the coils undergoing commutation. In the induction motor a somewhat similar reduction in reactance was accomplished, but this was not considered as the primary object in chording. The saving in the length of the coils, better flux distribution of the main field and the ability to obtain the equivalent of a fractional number of turns were all considered of more importance. This improvement in induction motor windings was also patented about this period.

It was along in the period from 1894 to 1898, that the writer actually constructed multispeed motors, by changing the number of poles in a given frame, as distinguished from cascade-parallel operation. This had been talked about a great deal, at different times, but there had been no occasion to build such motors. However, in some preliminary considerations for electrifying a certain large railway, the possibilities of polyphase current were taken up. Mr. Westinghouse suggested that a pair of induction motors be built with a view to determining whether satisfactory characteristics were obtainable for railway work. In order to simplify the outfit, motors with cage secondaries were considered and two large motors were built for four poles and 25 cycles. These motors were made with very high starting torques,—about six or seven times full load, the reactance being made purposely very small, so that the motors could have relatively small slip at full load and yet develop very high starting torque. It was the intention to control the speed during starting by varying the voltage supplied to the motor, an induction regulator being used for this purpose. Two motors and a regulator were built, but the system was found to be quite unsuitable for the purpose, partly due to the fact that only one speed was available. To overcome this, the writer then devised an arrangement for recoupling the primary winding to give eight poles as well as four. This was then tried out and it was found that both the four and eight pole speeds were quite effective. As far as the writer remembers, this was about the earliest large work in pole changing.

Among other objections raised against this proposed a-c. railway system, was the use of two trolley wires. The suggestion was made that such a system should really be single-phase. With this in view, as an experiment, the writer then operated one of the two special railway motors across *one phase of the supply circuit* and from it, as a phase converter, fed polyphase current to the four-pole-eight-pole motor. The tests showed that this latter machine, operating as a polyphase motor, acted quite satisfactorily on both the four-pole and eight-pole combinations. This, therefore, was an anticipation, experimentally of the split-phase traction system, which came out many years later. This feature of transforming from single-phase to polyphase by means of an induction motor, however, was not new or unknown at this time; for it had been brought

out very clearly by the General Electric engineers, in connection with the monocyclic system already mentioned, that if the monocyclic supply system could once get a large induction motor in the system up to speed, this motor would be of direct assistance in the starting of other motors, due to its phase converting qualities. It had even been claimed that with one induction motor up to speed, the "teaser" circuit of the monocyclic generator could be cut out, and the induction motors themselves would maintain the polyphase characteristics, provided all the phases were tied to the circuits. Thus it was known very early that the induction motor possessed these "phase-splitting" characteristics. The above tests for phase splitting with a polyphase railway motor are interesting merely as an attempt to obtain railway operation in this manner and also as early anticipation of much later practise.

The introduction of the cage type secondary, had a considerable bearing on the development of multi-speed motors, for a properly proportioned cage secondary could operate fairly well with various combinations of poles; whereas with the "polar" type of secondary, one winding was suitable for only one speed, without considerable reconnection, which was not convenient in practise with the relatively small motors in common use in those days.

Shortly after the above experiments with the two sets of poles on a railway motor, the writer designed various two-speed and three-speed induction motors for special purposes, some of which are in operation at the present time, after more than twenty years. An interesting and curious incident occurred in connection with one of these early commercial motors. A two-phase two-speed motor for four and eight poles was designed and built, using a single primary winding which was recoupled for change in poles. On this motor some mistake was made in the primary connections and it was discovered that, under certain conditions of switching, an effective twelve pole speed was obtained. This was not on the program, and was considered quite interesting and an attempt was made toward investigating the reasons for it. It was realized that this result was due to some mistake in the internal grouping of the coils and the writer set about determining the cause. However, before a proper examination of the winding itself was made, the winding department men got hold of the machine, and, knowing that there was a mistake somewhere, they disconnected the winding completely and reconnected it. Thereafter the machine would not show the twelve-pole speed, and neither could the shop men give any explanation as to what changes were made. Thus we were unable to make any complete tests or any investigation in the actual machine to find the reasons for this curious speed combination, and, furthermore, we were never able to work out a possible combination which gave the three speeds, as shown in the preliminary tests. Here, therefore, was a lost characteristic or combination, which might have proved useful, but which, on the other hand, on more complete tests, might have proved unsatisfactory. The writer took up the study of this problem at odd times during the next year or two, but eventually gave it up. It, therefore, stands on his records as one of the mysteries or unsolved problems in his engineering work.

The period from 1894 to 1900, might be called the "Golden Age" of induction motor development. Nearly all the things that have been developed since, originated or were first put into practical use during this brief period. During this time the induction motor business was practically revolutionized by the introduction of the cage winding with high starting torques. In this period the polyphase motor became so thoroughly established as a commercial device that it was already taking the offensive against its d-c. rival. During this time the theory of the induction motor was worked out and applied in practical forms of calculation, and the methods of calculation, developed in that time, hold with slight modification until today. The method of analysis and calculation derived by the writer in connection with the development of the cage tyye motor, as already described was used throughout the following years by the Westinghouse engineers and is the basis of their present methods. In the General Electric Company the methods devised by Dr. C. P. Steinmetz, during this period, are also used very generally throughout that company. These methods are naturally closely related to each other, although expressed in somewhat different form. The writer's paper "The Polyphase Motor," presented in 1897 at the convention of the N. E. L. A. at Niagara Falls, which is a non-mathematical exposition of the subject, was a direct outcome of his work on the cage type motor and his methods of calculation, and many of the curves shown in that paper were derived directly from his formulas.

Among the early analysts was Mr. B. A. Behrend, leading technical expert of the Bullock Company and later of the Allis-Chalmers Company. His early book on the induction motor was an exposition of fundamental principles and practises well worthy of study now, after twenty years, even with the great advances and developments in the art.

Indeed, this period might be called the "Age of Induction Motor Analysis," as well as development, for practically all the modern analysis is based upon fundamentals developed during this time. All the analytical work was not published, but the methods of those times were carried into the practical fields, with marvelous results, and it may be said that the methods of today are largely refinements of those of twenty years ago. These refinements in methods

have led to refinements in the machines, but not to any new principles which have allowed any radical departures in types.

By 1900, the induction motor had become pretty thoroughly established, with the cage type of construction far in the lead of all others. In fact, the enthusiasm for this type was so great that in some applications it was used where the wound-secondary type would have been superior. It took time, however, to determine its true limitations and its handicaps.

The period beginning about 1900, was one of application rather than of new developments of the induction motor. In Europe, the Ganz Company was applying the induction motor to locomotive work, in Italy. Eventually Mr. Westinghouse bought the American rights of the Ganz patents, but never used them. However, in this country one early attempt was made at electric traction by polyphase current, namely, on the Miami & Erie Canal near Cincinnati, by substitution of small locomotives for mules for towing the canal boats. A track was laid along the banks of the canal and two overhead trolley wires were installed. The locomotives were of comparatively small capacity and each was equipped with two three-phase motors adapted for cascade-parallel operation. The overhead voltage was 2000 and step-down transformers were placed on the locomotives.

In operation these polyphase electric locomotives did all that they were expected to do, and yet the installation was a failure, due to reasons outside of electric operation. In the first place it was intended that each locomotive should pull a series or "train" of canal boats, but in practise this was not feasible, at least on this particular canal. As the engineer on the job reported, the first boat of the train "piled up" the water ahead of it, thus lowering the level behind, the second boat did the same, and the fifth or sixth boat, in consequence, was dragging in the mud. In other words, the train of canal boats acted somewhat like the old fashioned chain pump.

A second trouble reported, which, however, was not necessarily a fatal one, is amusing in showing how the effects of little things sometimes are unforeseen. In the days of mule towing, the mules kept the grass down, along the tow path. However, with electric towage the grass grew so high that the locomotive pushed it over on the rails where it acted like a good lubricant so that, in some instances, the traction diminished to almost nothing. This trouble, however, could have been overcome, in case that the boat-towage had been more successful. After operating this system for a short time it was abandoned as impracticable.

Some years later, the General Electric Company installed polyphase locomotives in the Cascade Tunnel of the Great Northern Railway. These were three-phase, 25-cycle, 1200 to 1500 h.p. equipments and were used primarily for hauling trains through the tunnel. A single speed, with rheostatic control, was used on this electrification. An interesting feature was the use of 6000 volts on the two overhead wires.

At a still later period, three phase locomotives were installed by the General Electric Company along the Panama Canal, for towing purposes. This latter is the largest application of polyphase current to traction in America.

Beginning about 1896 and '97, steps were taken to apply induction motors to crane and hoist work. Among the earliest crane applications, were cage-wound induction motors with high-resistance secondaries and with means for supplying variable voltage to the primary windings for obtaining speed control. Quite a large number of crane equipments of this type were installed and the writer believes that some of them are still in operation. However, in general the polyphase motor for crane work has never been considered as fully competitive with direct current, due to the greater complexity required in polyphase crane trolley systems.

In the same way early attempts were made to apply induction motors to hoisting work. Both cage type motors and wound-secondary types were tried out and in some cases both were successful, in other cases both were failures, due, however, to misapplication in some instances. In later years more success attended such application due to a better understanding of the problem.

Induction motors quite early were applied to elevator service, especially for freight elevators. In the early days a high-resistance cage secondary was the preferred type and, in many cases, for low-speed service, such motors were thrown on and off directly without any control apparatus. Gradually, however, the opinion grew that the cage type motor did not fit such application as generally as the wound type. Quite recently there is a return to the squirrel-cage type, but with pole changing for two speeds.

About 1900, the induction motors began to extend to quite large sizes. The self-starting synchronous motor had not come yet, to any extent, and, therefore, practically all large power applications were through induction motors. These began to appear in 500, 1000 and 2000-h.p. sizes, sometimes of the cage secondary type, but quite frequently with wound secondaries; for the starting problem was recognized as of more or less controlling importance in these large motors. It must be remembered that in this period the present huge power plants were not even dreamed of, and generators of 2000 or 3000-kv-a. capacity were considered quite large. In consequence, the starting of a 2000-h. p. motor, especially if it was necessary to develop considerable torque, was a matter of much importance, for the reactive effects on the generator were liable to be serious, if not disastrous.

Power Factors

Almost from the first, it was recognized that the induction motor, in its normal form, would always have a power factor considerably less than 100 per cent, due to the fact that its magnetization was represented by

a reactive current drawn directly from the supply system, and, therefore, at full voltage and full frequency. It was also known quite early that the so-called magnetic leakages or stray fluxes gave reactive e. m. fs. which affected the power factor. However almost as soon as the designers began to calculate the induction motor characteristics, it was noted that the smaller the number of poles, the lower would be the magnetizing current. In fact, this was obvious from their knowledge of direct-current design. Consequently it was soon recognized that 25-cycle motors with their smaller number of poles, would require less magnetizing current than 60-cycle motors, and, therefore, such machines would naturally show higher power factors, due both to the smaller magnetizing current and the low reactance voltages. Consequently, in the earlier days the 25-cycle motor was looked upon quite favorably, due largely to its better performance This was particularly true where low speeds were desired, requiring motors with a relatively large number of poles. In the early days, in many of the larger applications, direct connection was considered as most desirable and, in consequence, relatively low speeds were required. In consequence, the frequency of 25 cycles was favored for industrial plants, due to the more suitable characteristics of the induction motors. In fact, this had a predominating influence in fixing the steel mill standard of 25 cycles, which was adopted nearly twenty years ago, after careful consideration by the steel mill engineers. In those days, many of the heavier steel mill operations called for speeds of less than 100 rev. per min. on the motors and this was considered prohibitive for anything but 25 cycles. Largely on this account, but also for other reasons, this frequency was adopted as the standard. However, at the time, this seemed to be very much in line with other practise, for central stations, transmission systems, railway systems fed from synchronous converters, etc. were all tending toward 25 cycles.

In steel mill work, in those days, heavy gears were looked at askance. However, in time, cases came up where gearing was desirable and with the need came the development of good reliable gears, so that in later years there has not been the same necessity for the low-speed induction motor as was formerly the case. In consequence, the tendency has been toward higher speeds with proportionately smaller number of poles, and, therefore, toward conditions which could be well met by 60 cycles. Furthermore, due to various causes, particularly the development of the 60 cycle synchronous converter, the general trend of the power systems throughout the country has been toward 60 cycles for both generation and transmission. In consequence there is some question today whether the old steel mill standard is not becoming obsolete. The interesting point, however, that it is intended to bring out, is that this choice of standard for mill work was fixed very largely by the induction motor design itself.

While the power factors on the early induction motors were quite good, yet when the type *C* motor came out, the quite remarkable results in power factor obtained with 25 cycles, was a subject for doubt and criticism at first. For instance, in a paper on the polyphase motor, delivered in 1897, before the N. E. L. A. Convention at Niagara Falls, the writer showed power factors as high as 95 per cent on certain 25 cycle polyphase motors. After the meeting, certain designing engineers, privately discussing the matter with him, said that this high power factor looked well on paper, but could not be obtained on actual test. The writer replied that the published results were obtained from actual test, and that they checked with the calculations. The critics then stated that if such was the case, they would accept the results as actual facts, but they considered them most marvelous.

In those days, power factors were not usually looked upon as simply representative of certain reactive components, and naturally it was not recognized by most people that a 95 per cent power factor represented a 31 per cent reactive component, whereas a 90 per cent power factor represented only 43½ per cent or only about 40 per cent more. A jump from a 90 per cent power factor, which up to that time had been considered quite good, to 95 per cent did really seem a marvelous and almost unbelievable result and yet, in fact, did not actually represent a very great reduction in the total reactive component. Even today many people think too much in terms of power factor rather than reactive component and are misled accordingly in many matters of importance.

Naturally, engineers quite early turned to the question of eliminating the reactive component in the induction motor. The possibility of reducing the magnetizing current quickly forced manufacturers to very small air gaps. In the very early motors a total gap of ⅛ in. ($^1/_{16}$ in. on each side) seemed extremely small and the manufacturing departments grudgingly accepted such narrow limits. However, before very long, and with more manufacturing experience, the air, gaps began to diminish until $^1/_{32}$ in. clearance on each side was considered quite satisfactory even in moderately large motors.

One of the first engineers to attempt to reduce the reactive component supplied from the line, was M. Leblanc, the well known French engineer. He proposed to supply the magnetizing current to the secondary of the motor instead of the primary, by generating in an auxiliary machine in the secondary circuit, suitable out-of-phase e. m. fs. which would circulate exciting currents in the secondary winding of the motor. Heyland, in Belgium, accomplished similar results by means of a commutator on the secondary circuit of the motor itself, by which the primary frequency could be converted to the secondary frequency at very low voltage, compared with the primary. Neither of these schemes, however, persisted for any length of time in Europe and neither of them were adopted

in America, at least not until many years later. Both of them involved the commutation of alternating current and, in the early days, this was considered a more serious problem than the reactive component of the motor input. In later years, many attempts have been made, and many schemes devised, in connection with correction of power factor of induction motors, but none of these have as yet come into general use, for they all involve the commutation of alternating current. This means complexity in the design of the induction motor, which apparently has not yet been accepted by the public in general. Gisbert Kapp, and Miles Walker, in England, have developed practical types of "phase advancers." Kapp's device has been tried out experimentally in this country by the Westinghouse company, while Walker's was built by the British Westinghouse company. The General Electric Company has tried out a form of the Leblanc phase-correcting device.

Developments from 1900 to 1910

The decade following 1900 was very largely one of growth as distinguished from development. In other words, the induction motor came in so rapidly and business was relatively so large that the manufacturing companies were busy extending standard lines rather than producing new types. This was a period of growth in size as well as in quantity. Also, due to greater refinements in application, etc., manufacturing companies were getting ready with new lines of apparatus, having improved characteristics, less weight, etc.

During the period from 1895 to 1905, the Westinghouse company, as well as other companies, had built many alternators with partially closed slots. In consequence, this construction was also carried into induction motor primaries and secondaries, so that the merits of partially closed slots were well known in the way of decreased losses, improved power factors, etc. However, practically all the moderate size and smaller induction motor primaries had been made with open primary slots, the "closed-in" slot construction appearing only on the larger machines. In attempting to obtain the merits of the partially closed slot machines for moderate and small size machines, the Westinghouse company developed a new line of motors called the type *CC*. This type had form-wound coils, without insulation except on individual wires, which were fed in through openings at the top of the slot. The insulation in the slot was a special cell. The end windings were then taped after being placed on the core.

This line of machines was about ready for the market when it became apparent that a somewhat lighter and smaller machine was desirable. In consequence, almost at once this new type was reconstructed, both mechanically and electrically, to form the type *C C L* line, which was then put on the market. This was the first radical departure from the type *C* line. It had many of the characteristics of the type *C* motors, but its efficiency and power factor were materially better. This line was on the market for a number of years, but it was found that many customers did not like the dropped-in type of winding, with partially closed slots, as repairs were more difficult than with the former open slot construction such as the type *C*. Moreover, when exposed to severe conditions of moisture, dirt and other foreign materials, the insulation on the end windings was assumed to be less satisfactory than the type *C* with its competely insulated coils. This condition, however, later was improved materially by dipping the end winding into insulating gums and varnishes. However, after a few years, with this type of winding, it developed that the operating public in general would be willing to sacrifice certain characteristics, to a slight extent, in favor of easier types of construction requiring less expert skill in repairs. In consequence, the open type of primary slot then came into general use in later constructions. This is not true, however, of the small sizes, for here the gains, due to partially closed slots, have been so great that they have apparently much more than offset the problems of repair, so that the trade in general has accepted the partially closed slot for the smaller motors.

In attempting to combine the advantages of the partially closed slot with those of the open slot construction, many manufacturers of induction motors, including the Westinghouse and General Electric companies have sought to develop and use some form of magnetic retaining wedge, which would serve to hold the primary coils in place and, at the same time partially close the slot magnetically. During the past ten years, many forms of wedges have been devised and many motors have been built with such wedges, and, within their limitations, several forms of these have given quite satisfactory results. In fact, this is still one of the active development problems in several of the manufacturing companies.

Speed Control of the Induction Motor

In applying the induction motor to steel mill work, many new problems have come up, and many new and unusual developments have occurred. Among the problems involved was that of obtaining speed adjustments, or variations, in an economical manner. Inherently the induction motor is a constant speed machine and has been recognized as such almost since the first. This being the case the motor has been applied with this limitation in mind, and, in consequence, there have been certain classes of service where the induction motor inherently does not fit well. Adjustments in speed in such cases must be obtained either by the use of some other kind of motor or by some mechanical means. However, in steel mill work, where large powers are involved, these indirect means have not been applicable, in many cases. Direct-current motors in large sizes are not desirable on account of voltage limitations, and

mechanical speed-changing devices on a large scale do not appear to be applicable or feasible. In consequence, pressure has been brought, by the needs of the situation, to develop means for obtaining the necessary speed adjustments or variations with induction motors.

Adjustable speeds, of course, are obtainable with induction motors by varying the supply frequency, but this is not a general solution as it involves means for obtaining variable or adjustable frequency, which usually contain the same difficulties as speed adjustment in the induction motor itself. Speed control is also obtainable by varying the number of poles in the motor, but obviously this is limited to a relatively small number of combinations, and fine graduations in speed are not obtainable. Speed control is also possible by means of a resistance in the secondary circuit, but speed changes obtained in this manner are uneconomical and the speed varies with changes in torque. However, if instead of expending energy in resistance in the secondary circuit, such energy is expended in some useful way such as in a motor, or other devices which can either utilize it or return it to the system, then economic speed control becomes possible. However, with each change in speed in the secondary circuit of the motor there is a new frequency and a new voltage and, consequently, any means for absorbing the secondary energy must be of a kind which is adapted for adjustable frequency and voltage. Obviously, therefore, we have simply transferred the variable frequency problem from the primary to the secondary, with this difference, however, that the secondary frequency is proportionate to the slip, and, therefore, for moderate slips on either side of synchronous speed the frequency involved will be relatively low. This is of direct importance, because a number of the practical means for furnishing low frequency are dependent upon alternating-current commutation, which, in general, holds certain relations to the frequency.

In some of the earlier mill work, where only two speeds were called for, either cascade operation of two motors or pole changing in one motor was resorted to. In 1906, the Westinghouse company installed a relatively large cascade set in the Illinois Steel Company, at Chicago. This set had twelve poles in one frame and twenty-four poles in the other, and was adapted for operation at speeds corresponding to 24 and 36 poles. This set is still in operation after fourteen years.

However, the cascade arrangement proved to be expensive compared with the use of two combinations of poles on one frame and in later work, requiring two speeds, single frame motors were installed as a rule, with their windings adapted for giving two sets of poles. Some very large motors of this type were installed in steel mills by both the General Electric and Westinghouse companies.

However, it gradually developed, both in Europe and in this country, that finer gradations in speed were necessary and, therefore, various methods were developed for obtaining close speed adjustment. Most of these methods were tried commercially in Europe before they were undertaken in this country, but, in recent years, practically all the available methods have been tried out commercially in one form or another in this country. The methods of speed control by utilizing the loss in the secondary may be considered as primarily three in number; (1) by converting the secondary frequency and power to direct current; (2) to mechanical power; and (3) by converting the variable secondary frequency to some definite constant frequency, such as the primary, by means of a frequency changer.

The first of these methods, utilizes a synchronous converter in the secondary circuit, converting to direct current, but at a variable voltage. This power can then be utilized by an adjustable-voltage d-c. motor. This method usually known as the Kraemer, had been much used by both the Westinghouse and General Electric companies.

The second method involves the use of a variable frequency motor, which of necessity is a commutating type a-c. machine. The variable-frequency secondary power is thus converted directly to mechanical power, in which form it can be utilized in various ways. This arrangement, known as the Scherbius, has been used quite extensively by the General Electric Company.

The third method involves the use of a frequency changer, which is also a commutating type machine. This method is practically the equivalent of the first method above, except that it transforms from one frequency to another instead of to zero frequency (direct current). This third method has been used recently by the Westinghouse company.

It may be noted that all these methods involve the use of extraneous devices for regulating the speed and, therefore, it may be said that this development should not be classed with the induction motor problems, but is really a control problem. In consequence, it may be said that this need for adjustable speed has not really affected the induction motor development itself, but has simply extended its field of operation, and has given to it some of the flexible characteristics of the direct-current machine, but at the expense of considerable complication.

Heavy Power Applications

Steel mill work is a good illustration of what happens in extending electric power application into heavy work. Originally the steel mill applications were largely direct-current, which presented the greatest flexibility in the motors themselves. However, before long, it was seen that the power requirements in general would overtax the direct-current type unless abnormal

voltages were used, and, in consequence, the trend was soon toward the alternating current, simply because of its capabilities in large powers and its flexibility as regards voltage. This had been the trend in many other lines, such as power station work, railway work, etc. Long ago the direct-current power station for railway work became obsolete and alternating current generation, with synchronous converters in distributed substations, took the place of the former direct-current power generating stations. In central station work, in general, the alternating-current system had driven out the direct-current type so long ago that the present generation knows practically nothing else. In direct-current generator work, machines of from 3000 to 5000 kw. have been considered as monsters, but in the alternating current work, single generators of 30,000 kw. are not uncommon. Therefore, the direct current system with its greater flexibility in speed control, etc. has not been able to hold its own against the alternating system with its greater flexibility in voltage transformation. This trend followed naturally into the steel mill business, for here motors up to 6000, 8000 and 10,000 kw. came into use many years ago and the need for such huge capacities has forced the situation to the alternating-current system throughout. When these huge horse-powers are referred to, it must be borne in mind that, in some cases, these also represented very low speeds, such as seventy-five revolutions. An 8000-h.p., 75-rev. per min. mill motor, represents almost the acme of design in induction motor work. Here the mechanical problems of construction may dominate the electrical. Such machines not infrequently have been made with purely engine type frames, similar to engine type alternators, which construction necessitates relatively large air gaps compared with other kinds of induction motor work. A total gap of ¼ in. could seem prohibitive in induction motors, yet such gaps and even larger have been used in some of these huge steel mill motors, as constructed by the larger manufacturing companies. Such machines are especially interesting when constructed for two speeds, usually involving two sets of windings in both the primary and the secondary elements.

Induction Motors in Railway Work

As already mentioned, the General Electric Company applied the induction motors to railway work in connection with the Cascade Tunnel on the Northern Pacific Railway. A much more recent application of such motors to railway work is the Norfolk & Western application at Bluefield, West Virginia. Here the induction motor appears in two radically different functions; one as a generator of power, in the main locomotive motors themselves, and the other as "phase generators" in the so-called "phase converters" which serve to transform from the single-phase trolley system to the three phase circuits for the motors.

As mentioned before, even back in the days of the monocyclic system, induction motors were used for "balancing" polyphase circuits. It was found in the very early days of the induction motor, (the writer does not know who first made the discovery) that when an induction motor was operated at full speed, on one primary phase from the supply system, polyphase circuits could be taken from the machine by simply tapping in on all the primary phases of the motor. In other words, if one phase or terminal of the motor should be disconnected from the line, that phase or terminal would still be active as far as voltage and phase generation was concerned. This principle has been applied many times, and in various ways, within the past twenty or twenty-five years. As mentioned before, the writer tried this method experimentally for operating a polyphase railway motor from a single-phase circuit, in the later 90's. Alexanderson also proposed this general scheme for railway work about twelve years ago, and the General Electric Company made elaborate tests on an experimental equipment. The scheme used on the Norfolk & Western locomotives

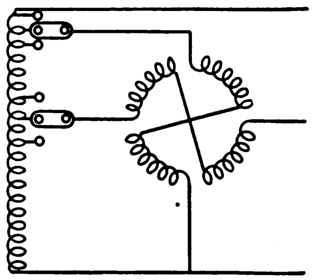

FIG. 10

is based on the same principle. In these locomotives, the phase converters are simply high-capacity induction motors connected to the circuit in such a manner as to transform from a single-phase supply system to a practically balanced three-phase motor system. The phase converter has a two-phase primary winding with a cage secondary. One of the two-phase windings connects across the secondary circuit of the step-down transformer, while the other phase has one terminal tapped to a mid-point of the transformer, thus forming the equivalent of the Scott transformer system. The two terminals of the transformer and the remaining terminal of the phase converter thus form a three-phase system, the proportions of the two windings on the converter being such as to give practically balanced three-phase relations. To compensate for unbalanced conditions with change in load, the tap at the middle of the transformer can be shifted back and forth a certain amount.

Induction Motors in Ship Propulsion

Another huge application of the induction motor, of quite recent date, is in the propulsion of battleships. This started only a relatively few years ago with the electric propulsion of the collier *Jupiter*,

by the General Electric Company, under the supervision of Mr. Emmet. This it might be said was an experimental equipment in the sense that its purpose was to find whether electric motors were suitable for the propulsion of large vessels. Based upon these results the Navy went into electric ship propulsion on a large scale so that at the present time there are nineteen large battleships and battle cruisers under contract for propulsion by electric motors, ten of these being built by the General Electric Company and nine by the Westinghouse. Only one of these has been in extended service as yet, namely, the *New Mexico* with General Electric equipment, this being the first battleship contracted for. A second battle ship, the *Tennessee,* with Westinghouse equipment, has only recently gone into service. The equipment of these battleships in general, may be of interest as showing special features of speed control.

In this battleship drives the main propulsion motors form the only load for the generators. In consequence, the frequency can be fixed by design conditions, such as the desired speed for the generators and propelling motors and this frequency can be varied up and down over a wide range by simply varying the speeds of the driving turbines. Thus speed control is primarily by means of primary frequency, this being one of the few instances where this is practicable.

As the desired steam economies can not be obtained at the lowest required speed with this arrangement, a change in speed by means of pole changing, or its equivalent, in the motors themselves is obtained. For example: The motors on the *New Mexico* and the *Tennessee,* and a number of other battleships, are designed for twenty-four and thirty-six poles. In the battle cruisers, however, a different combination is used as will be mentioned later.

In ship propulsion by electric motors such as the above, there are several conditions which are very favorable to the electrical equipment, and which make the whole operation relatively simple and easy compared with other kinds of motor operation. In the first place, the motor is not tied rigidly to its load, as is the case, for instance, in locomotive work. In other words, the motor can start and come up to speed long before the ship has reached its full speed. On this account the secondary losses, rheostatic or otherwise, can be made very low, for the motors come up to speed in a very short time, while the boat may take many minutes to obtain full speed. If it were not for this feature, the rheostatic loss in starting and accelerating would be enormous, unless all such starting was done by means of speed adjustment of the turbine. As it now stands the propeller acts as a slipping clutch which gradually pulls the motor up to full speed without undue load on the motors themselves and with principal expenditures of power at the propellers themselves, which produces no harmful heating.

In the second place, the switching of the motors can be done without power. In other words, the excitation can be cut off from the generator when it is desired to switch the circuits, such as for pole changing or for reversing, for it is not necessary to maintain the driving torque at all times, as is the requirement in locomotive work. When drawing a locomotive up a grade, for instance, the tractive effort must be maintained during the operation of switching and this is one of the features which makes the problem difficult. In ship propulsion, on the other hand, this condition is absent or is of minor importance.

A third favorable condition in the ship propulsion problem is that there is no need for parallel operation of the generators.

In the *New Mexico* and the *Tennessee,* there are two generating units and four motors. For the higher speeds two motors are operated from each generator and, for lower speeds, four motors are operated from one generator. In the larger units, such as the battle cruisers, there are four generators and four pairs of propeller motors. At the highest speed there is one pair of motors on each generator. At intermediate speeds there are two pairs of motors on each of two generators, while at the low speeds there are four pairs of motors on one generator, but at no time is there any occasion for paralleling any of the generators. This simplifies the whole proposition materially.

On account of the huge capacities of the propelling equipments, not only is alternating current required but relatively high voltages. On the *New Mexico,* the *Tennessee,* and vessels of the same class, there are four main motors of about 7000 h. p. each, operated from two generators of suitable capacity. The size of these equipments necessitates a maximum operating voltage of about 3500. This voltage, of course, decreases with reduction of frequency in speed control.

In the battle cruisers, however, where there are four pairs of motors, each pair consisting of two 23,000 h. p. motors on one propeller shaft, the power of the motor is such that a maximum operating voltage of about 5500 is needed. Considering the possibilities of salt spray, etc. some very difficult problems are involved in the use of such voltages on sea-going vessels. On the battle cruisers a two-to-one combination of poles is desired instead of three-to-two on the smaller vessels. In consequence, here either pole changing or simple cascade arrangement of the motors is permissible.

On the speed control of the motors themselves, during starting, two radically different arrangements have been put out by the General Electric and Westinghouse companies. In the *New Mexico,* equipped by the General Electric Company, the two-phase motors are of the double cage secondary type, that is, the secondaries of the motors are equipped with two cage windings, the outer one, that is the one next the air gap, being of relatively high resistance for starting and accelerating and the inner one being of relatively low

resistance. Between these two windings is a sort of magnetic bridge for introducing a certain amount of reactance for the bottom winding. During starting and acceleration, the high-resistance winding furnishes a considerable part of the torque, whereas at full speed the low-resistance winding becomes effective. These two windings are proportioned to give the required torque results with both the 24 and 36 poles. Many problems of expansion, etc. came up in the development of this cage winding and, in fact, the end rings of the secondary contain what might be called "expansion joints."

In the contract for the *Tennessee*, which came later than the *New Mexico*, the Westinghouse company designed their motors for three-phase current, using two primary windings, one for 24 poles and the other for 36. The secondary winding is of the wound type and is connected to the collector rings in order that a starting resistance can be inserted. Certain cross connections on this 24-pole winding automatically act as short circuits when the primary is thrown to 36 poles, so that the secondary automatically becomes short-circuited under this condition. The rheostat is, therefore, inserted only for control on the 24-pole combination, the 36-pole being simply a running speed.

In later equipments of the *Tennessee* and *New Mexico* types of ships, the General Electric Company arrangement is somewhat different from the above, according to the information which the writer has received. Here there are apparently two windings on the secondary, one being a high-resistance winding equivalent to the cage type, while there is a 24-pole winding of the distributed type, which is inoperative on 36 poles, but which is short-circuited on 24 poles. The high-resistance cage winding is in circuit on both 36 and 24 poles.

While this arrangement, on the face of it, does not look as simple as the double cage of the *New Mexico*, yet it is intended to give better speed-torque and power factor characteristics.

On the battle cruisers the writer does not know what motor combinations are used by the General Electric Company, but in the Westinghouse, a special cascade arrangement is used to give half speed and lower. As the motors were laid out with wound secondaries, this cascade arrangement involved little or no additional complication for cascade operation.

In the super-dreadnoughts, which were contracted for after the battleships and battle cruisers, four motors of about 15,000 h. p. each are required with two generators of necessary capacity. The general arrangement is, therefore, quite similar to the battleships, except that the power requirements are practically double. In the Westinghouse equipment, the motors are for 24 and 36 poles, each motor containing two primary and two secondary windings, each secondary winding being suitable for starting on resistance.

It may thus be seen that this electric propulsion of large ships is not a radical undertaking. The motors are huge in capacity, but their speeds are such that from the mechanical standpoint they are not nearly as large as some of the steel mill motors which have been in operation for many years. One of the principal problems has been in the ventilation, for the equipment has to be installed in confined spaces and, therefore, artificial cooling has been resorted to in all cases. In fact, this has been possibly the most difficult problem in the whole design of these huge equipments.

This brings the induction motor up to the present. Its history has been a most interesting one to those who are at all familiar with it. To a certain extent this type of apparatus stands apart, in that its development has been due, almost entirely, to the analytical engineer. It is almost impossible to conceive that the induction motor could have been developed to its present high stage by ordinary "cut and try," methods. Some good motors might have been obtained in that way, but they would have been accidents of design, instead of the positive results of analysis, as the art now stands.

New applications are continually leading to new developments which are worked out by the analytical designer with an assurance of success not exceeded in any other branch of the electrical art. And the result of all the elaborate theory and complicated analysis and calculation is a practical machine of almost unbelievable simplicity and reliability;—a standing refutation of the too common idea that complexity in theory leads to complexity in results.

AUSTRALIAN STEAM-ELECTRIC PLANT TO USE 50-CENT COAL

Construction is to be started April 1 on a 125,000,000 kw. steam-electric plant, 112 mi. from Melbourne, Australia, according to announcement from Australian government offices. This is a governmental undertaking, to be carried out by the Victoria Electricity Commission, which proposes to develop extensive coal deposits at the plant sites, use the coal for generating electrical energy and transmit the power electrically to Melbourne and other industrial centers. Included in the project for which immediate construction is planned are a total of 1800 mi. of high-tension transmission line and three terminal substations. The trunk line voltage will be 132,000.

The coal deposits are said to be very extensive, . . . The coal can be delivered to the power house for about 50 cents per ton the report states. Condensing water is supplied by a river alongside the power house. . . . . .—*Engineering News-Record.*

Some Phases of Railroad Telegraph and Telephone Engineering

BY STANLEY RHOADS

Telegraph & Telephone Engineer, New York Central Lines

Statement of size of N. Y. C. Lines telegraph and telephone plant and variety of engineering problems involved. Telephones used almost exclusively for train dispatching, not so general for message work, but growing. Automatic telephones used. Extensive local and long distance lines and switchboards. Telegraph system reaches all stations. Pole line is basis of plant, increasing in strength to meet safely the loads to which subjected. Railroad employs wire chiefs.

Problems include electric protection, inductive interference, electrolysis, transmission, traffic, necessitating continual experiment and investigation. Telegraph answer-back used with selectors. Phantom telephone circuits used. Single wires for railroad telegraph obsolete; all wires used in simultaneous telegraphy and telephony. Extra high impedance telephones used for train dispatching. Iron wire joints welded. Battery consumption data; unit type switchboards designed, supplant dry battery for main selector ringing battery; chemical rectifier also used. Oscillograms of single-line telegraph current waves, when line insulation varies. Railroad long-distance lines can be loaded.

Telephone selector current waves given. Gill local bell selectors used with repeat coil signaling to obtain low-resistance simplex. Duplex telegraph used on about 10,000 miles of circuit on N. Y. C. Lines. Polar duplex is approximate three-wire circuit. Self-balancing duplex designed, especially adaptable at unattended repeater stations; oscillograms illustrating results in better balance of duplexes. No. 5-U retard coil of standard bridging duplexes and quads is auto-transformer as well as retard coil; is useful as retard, detrimental otherwise. Polar relay armature of differential duplex and quadruplex has more force than in bridging. Differentially connected relays are transformers to some degree. Inductive effects of differential sets. Standard quadruplex, common side, is too sluggish for hand-operated sending machines. Defects of quadruplex discussed. Limiting practicable lengths stated for various kinds of wire for telegraph and telephone circuits.

THE railroad telegraph and telephone department entered a new era when telephone train dispatching was adopted 13 years ago. In the last five years electrical engineers have been employed in this department in increasing numbers, and the development has become more rapid. Previously the telegraph and telephone departments of the railroads were content to depend on outside interests for ideas, equipment, methods of operation and development, and as a result the development was slow. The staff of one railroad telegraph department, with engineers continuously employed, has procured considerable advancement in the railroad telegraph and telephone plant in a space of four years, perhaps as much as was accomplished by all railroad telegraph and telephone departments in the four years previous to the period mentioned. This is attributed to the intensive application of electrical engineers to practical problems and obvious requirements of railroad service.

A difficulty confronting the engineer in the investigation of a problem, is to learn the state of the art in relation to the particular problem in hand. It is somewhat with the idea of presenting some data on the state of the art, as applied to railroad telegraph and telephone systems, that data and results of investigations are given here. It is hoped that any incomplete investigations can be continued by the engineers of the New York Central Lines and others; that any false conclusions can be pointed out, and that the data here presented may suggest investigations along other similar lines and on related problems.

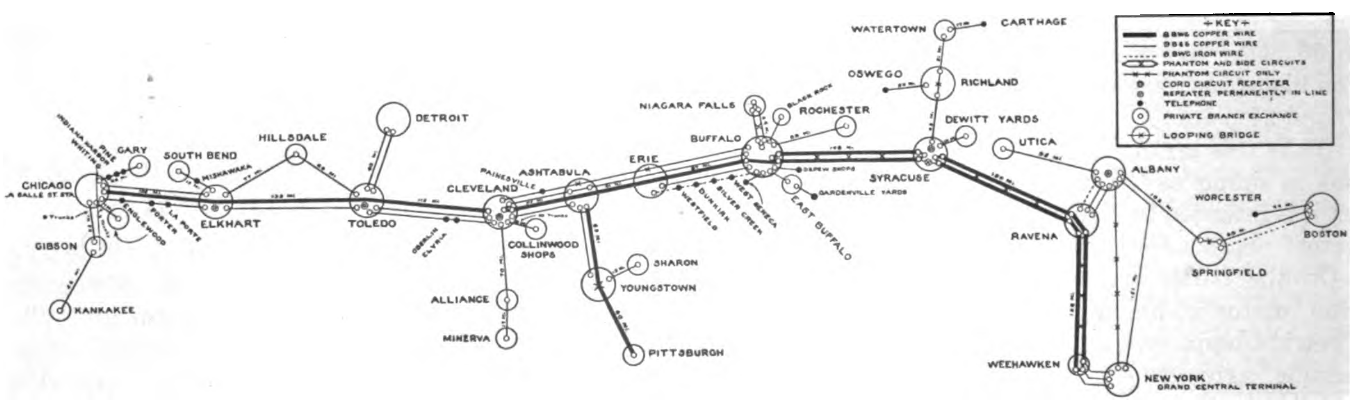

FIG. 1—NEW YORK CENTRAL LONG-DISTANCE TELEPHONE LINES

In order to interest others than railroad engineers in these problems, it can be said that the railroad telegraph and telephone engineer, particularly of the

Presented at the 9th Midwinter Convention of the A. I. E. E., February 16-18, 1921.

larger railroads, has problems of a variety that includes a little of about everything confronting the plant and traffic engineers of the large telephone and telegraph companies that have nation-wide service. The extent and distribution of the plant are the chief differences. This variety gives absorbing interest to the work. As the staff of the telegraph department is small, its engineers are obliged to handle any problem that arises as best they can.

New York Central Lines Telegraph and Telephone Plant

The plant under the supervision of the New York Central Lines Telegraph Department comprises 6 per cent of the total Western Union pole line and 12 per cent of the wire, and includes 12,000 miles of pole line with 80,000 miles of copper

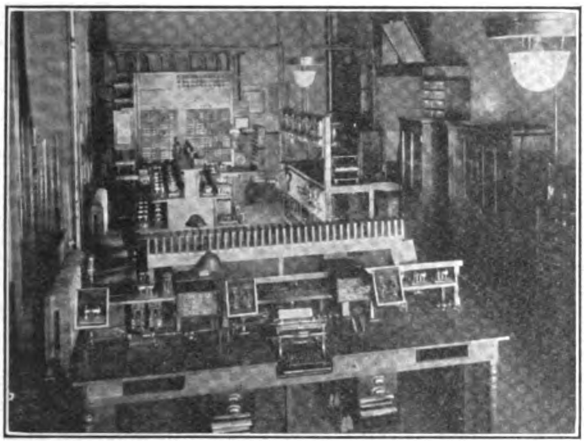

Fig. 2—C. C. C. & St. L. Ry., St. Louis Div. Headquarters Relay Telegraph Office

wire, of which 40,000 are used by the railroad; 76,000 miles of iron wire, of which 25,000 are used by the railroad on 12,000 miles of rail line. This includes a New York-Chicago long-distance telephone line, shown in Fig. 1, which has telephone repeaters, composite equipment, phantom circuits, and loaded cable. Practically all other important points from New York and Boston, to St. Louis and Chicago are connected in the network of service. Vacuum-tube telephone repeaters are installed at Albany, Syracuse, Cleveland, Toledo and Elkart, with one or two additional stations soon to be installed. These lines connect railroad telephone exchanges in some cases larger than required to serve the public in small cities. The total number of long distance calls handled is about 5000 calls per day. New York and Chicago have 12 position boards, and others are in proportion to the amount of business done. The New York Central Lines have about 5500 telephones on P. B. X. boards and 4000 direct exchange lines. The number of local calls is enormous, but is not kept count of ordinarily. City calls are counted by the telephone companies in order to make the billing where this is on measured rates. These boards are operated by the railroad, but furnished and generally maintained by the Bell telephone companies. The railroad offices in large cities have numerous one-position sub-boards in various departments.

The railroad telegraph service with its network of 40,000 miles of copper and 25,000 miles of iron wire in its own service, reaches 3700 offices. The centers of operation at headquarters of the general staff of the railroads have large offices called general telegraph offices. The division headquarters telegraph offices are called relay offices. Such an office at Mattoon, Ill., is shown in Fig. 2. This office serves two telephone dispatching circuits, four telephone message circuits, two phantoms, four yard lines, two Western Union way Morse wires, four railroad single-line Morse wires, two of which are connected through repeaters, three duplex Morse wires, two of which are connected through repeaters. New York has a force of 20 telegraph operators, Indianapolis 18, Detroit 16, Chicago 14, Cleveland 13, and other cities in proportion.

The telegraph service is more extensive than the telephone long-distance system, because it must reach every station and office on the system; whereas, the telephone long-distance service is limited to the officers and employes who have Bell telephones that connect to the railroad telephone exchanges, and the way stations in general do not have access to the long-distance lines.

Direct through service is maintained between the important centers and in nearly every case between adjacent division terminals. For example, New York has a direct Cincinnati wire, also one each to Chicago, Detroit, Cleveland, Buffalo, Rochester, Syracuse, Watertown, Corning, Albany and Boston. Single Morse has the greater total mileage, duplex Morse next, but only a small amount of quadruplex is used because of its limitations.

The thirty New York Central Lines relay telegraph offices handle about 55,000 railroad telegraph messages per day. No attempt is made to count the messages handled by one way station with another, unless they are relayed or sent or received by the general or relay telegraph offices. The way-station operators receive and transmit Western Union commercial messages in addition to the railroad messages.

Some printing telegraph service is employed between relay offices. At present, this is limited to New York to Albany and Cleveland to Toledo. The operation is duplex, single channel, Morkrum type in both cases. In the hand operation, single, duplex and quadruplex service is employed.

The telephone is used almost exclusively for train dispatching on the New York Central Lines, consisting of 108 circuits, with 3020 selectors on 10,271 miles of railroad. It is also being extended for way-station message service on dispatching divisions, but is at present in use on 48 circuits with 1464 selectors, less

than half the total New York Central Lines mileage. When business returns to normal it is expected that this service will rapidly extend until the railroad is on a complete telephone basis. Several different types of selectors and telephones are in use for these dispatching and message circuits.

Two railroad automatic telephone systems are in service, one at Detroit and one at New York in the electric division, neither of which is connected to the Bell telephone system. The New York installation comprises five interconnected exchanges, with 600 stations. The system centers in Grand Central Terminal but has exchanges connected by trunks, at West 72nd St., Mott Haven, Harmon, and White Plains. The latter two are each about thirty miles from New York. An immense volume of traffic is handled on this system. The Grand Central Terminal board handles about 2000 local calls per day, 500 incoming trunk calls, and 700 outgoing to and through Mott Haven. The high hourly load is between 3 and 4 p. m., during which period about 600 local calls are handled daily.

The privately owned telephone cable plant is gradually extending. It now extends nearly twenty miles out of New York on both the Hudson and Harlem Divisions, and will extend eventually thirty miles on each. In other cities the private cable plant is growing in proportion. In the New York territory loud-speaking telephones are used for train dispatching, also for train announcing between interlocking towers in the vicinity of Grand Central Terminal. "A" tower on the upper level of Grand Central Terminal has in use almost all practicable methods of wire communication, including, Bell and automatic telephones, telautograph, loud speaking telephone circuits, lamp signal annunciators, bell annunciators, private line telephones, and selector telephone train dispatching and message lines. Private line telephone connection is provided between ticket sellers at the stations in the larger cities and the Pullman reservation departments in the same cities, over which reservations are handled. The telephone system is specially designed for this service. Some lines are provided from the reservation desk to the regular telephone switchboard. Special boards or tables are provided for passenger train information at the larger terminals, connecting with the regular telephone switchboard, as well as direct to the Bell city exchange.

The construction and maintenance of the pole lines, except some private line and cable, is under the supervision of the telegraph department in accordance with the contract with the Western Union Telegraph Co. and under the specifications of the latter after approval by the railroad. The installation and maintenance of the inside telephone plant is under the supervision of the telegraph department and is performed under the railroad's own plans and specifications. The telephone companies install and maintain the rented telephones and switchboards. The inside telegraph plant is installed and maintained by the railroad chiefly under Western Union Telegraph Company specifications under the contract between the two companies.

The pole line is the backbone of the telegraph and telephone plant. Railroad pole line construction in the past has been very largely based on the average-strength plan, which for a given load of wires provides that the class of poles shall be the same regardless of the extent of the exposure to ice and wind. No estimate is available to indicate how much of the average-strength type of line is too weak, too strong or just strong enough. Lines that are stronger than necessary have cost the

Fig. 3a—Line Replaced Modern Pole Line

railroads more than was warranted for their construction, while those that are too weak will require large expenditures for maintenance, particularly after severe storms when stretches may be laid flat. Additional losses result from service interruption. Such interruptions not only consist of the loss of wire service, with the consequent train delays, but may result in a blockade when poles fall across main tracks, as has happened frequently.

In order to reduce the pole line damage and traffic interruptions to a minimum, railroad telegraph and telephone engineers have worked out an exact strength

Fig. 3b—Way-Station Installation

of line with an allowable factor of safety based on wind and ice data for the localities in which the lines are located or are to be built for use in construction and reconstruction work. Wind and ice data may be determined readily in any locality so that railroads can construct lines on an exact strength of line basis with a proper factor of safety which should result in economy.

The reconstruction of pole lines along the New York Central Railroad is now being handled on this basis.

The desirable line consists of a cable and not more than two arms of open wires. Fig. 3A shows this type of line at Cleveland, Ohio, built on the factor of safety or exact strength design, also the old type of line which it replaced.

The type of telephone and telegraph installation now approved for way offices includes a metal box unit containing electrical protection, cross connections and terminal blocks; metal box units with porcelain panels and very substantial jacks, for patching and testing circuits; factory made cables; caustic soda primary battery common to transmitter and selector bells; and conveniently located table apparatus Such an office is shown in the two views of Fig. 3B, in which the door of the metal box containing the electrical protection, is open.

The wire testing is performed by an organization of railroad wire chiefs, each testing office having about one operating division to supervise, which is, roughly, one hundred and fifty miles of railroad. Many of these points have three "tricks," that is, a wire chief is on duty at all times. Others have but two men per day and some have but one. Wheatstone bridge testing methods are used; also the voltmeter and milli-ammeter. The station linemen maintain both pole lines and station equipment on most of the New York Central Lines.

Problems arising from the construction, maintenance and operation of the railroad telegraph and telephone plant include electrical protection, inductive interference, electrolysis and telephone and telegraph transmission and traffic. Investigations and experimental work are continually necessary in various phases of the engineering. The oscillograph of the Electrical Engineering School of Purdue University has been available for about five years in these investigations, the major part of which has been made on actual working lines.

Telegraph Traffic Problems

Telegraph censors are employed on two of the New York Central Lines for the purpose of reducing unnecessary telegraphing and telephoning and reducing the number of words in necessary telegrams. A large part of the duty is educational in giving other departments an idea of the proper use of the telegraph. The results accomplished are more than enough to justify the expense. One failing that has been reduced is the tendency to let messages stay in the originating office until closing time at night, sending them to the telegraph office at the same time the train mail is sent to the mail-room. This overloaded the telegraph office at a time when outlying offices were closing for the day and many such late messages would be held over until the next day. The telephone traffic is more difficult to censor, as no record of subjects of conversation is made—an unnecessary message must be caught in the act of transmission. Rules are in effect which prevent unlimited use of the long-distance telephone service, calls for the higher officials being given preference.

No charge is made against any department for the railroad telegraphing done by it and no records are kept for that purpose, but a numbering scheme is employed to give a check on the volume of business and the cost of handling it. The railroads have quite generally adopted a numbering scheme for telegraph messages based upon counting one number for each message of three lines or less, an additional number for each additional three lines, and an additional number for each additional address if addressed to more than one person. Ten words are counted as a line; extra numbers are allowed for reports which are termed "make ups." Only the larger offices keep such a record; that is, way stations do not. The division relay offices make a daily and monthly record of messages handled, which, on the New York Central Lines, are compiled and presented graphically as shown in Fig. 4, which shows total messages handled per month, the cost per message and the average number handled per man per hour.

An analysis of the messages handled on three different circuits is interesting and is tabulated below:

TABLE I

	New York-Albany Morkrum printer	New York-Chicago operator	Big Four Route operator
a. Number messages reported...........	441	391	348
b. Correct number messages..........	367	387	357
(Difference between a and b is operators' error in recording numbers handled.)			
c. Actual number pieces paper.............	259	245	261
d. Actual minutes required	165	379	328
e. Number per minute..	$\frac{367}{165} = 2.22$	$\frac{387}{379} = 1.02$	$\frac{357}{328} = 1.09$
f. No. per man per hour	66.72	61.25	65.25
g. Possible number per 8 hours...........	1065.6	490	522

The above mentioned printer circuit is duplexed and the total number of messages possible in eight hours includes the total sent in both directions. One man only, at each end, is needed and each can send one-half the total, or 533 messages, in eight hours. On the ordinary Morse circuit it requires two men, one sending and one receiving, to handle this number of messages.

The printer receives with scant attention, and the possible 1065.6 would be reduced if the circuit were in trouble or failed to transmit perfectly. The evidence is plain that the printer will handle about double the load with one man at each end, that a Morse wire will

handle. Including all items of cost, operators will handle the business cheaper than the printer up to a total of about 400 numbers, including both sent and received, but this varies with rates paid operators, etc.

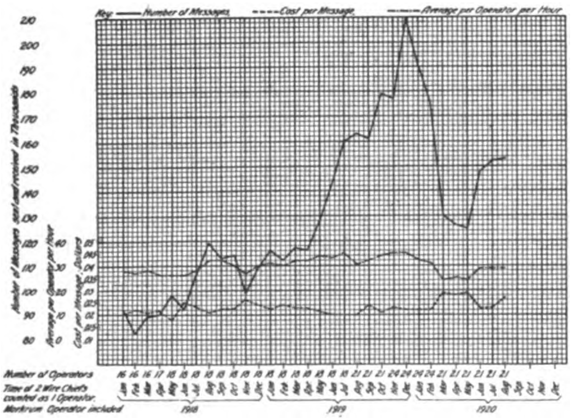

FIG. 4—TELEGRAPH TRAFFIC RECORD, "Q" TELEGRAPH OFFICE N. Y. C. R. R., NEW YORK

The averages of Table II indicate that nearly 35 per cent of railroad messages are one line or less; 35 per cent are one to two lines; perhaps, 15 per cent are two

TABLE II

	N. Y.-Albany	% of 259	N. Y.-Chgo.	% of 245	Big 4	% of 261
Actual number pieces paper	259		245		261	
1 line or less	88	34.0	93	38.0	68	25.0
1 line to 2 lines	98	38.0	79	32.2	91	35.5
2 lines to 3 lines	20	8.0	35	14.3	55	21.1
3 lines to 6 lines	45	17.0	31	12.7	38	14.4
Over 6 lines	8	3.0	7	2.8	9	3.5
Extra count for excess over 3 lines	66	....	49	....	79	....
Extra count for make-ups and joints	42	....	93	....	17	....
Total numbers	367	....	387	....	357	....

to three lines; 10 per cent are three to six lines and not more than 5 per cent are over six lines. This indicates that 85 per cent of the messages are less than

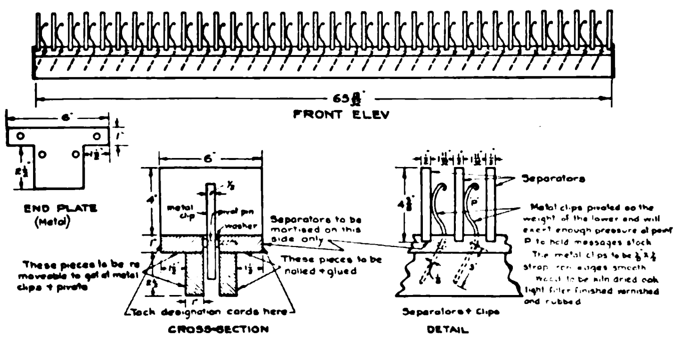

FIG. 5—OPERATORS' TABLE RACK FOR HANDLING MESSAGES TO BE TRANSMITTED

three lines and small error would result if only one number were counted per message regardless of the number of lines.

A mechanical device, which the railroad designed for assisting in prompt handling of outbound messages, is shown in Fig. 5. It can also be seen on the telegraph operating table in Fig. 2. It is a gravity clip

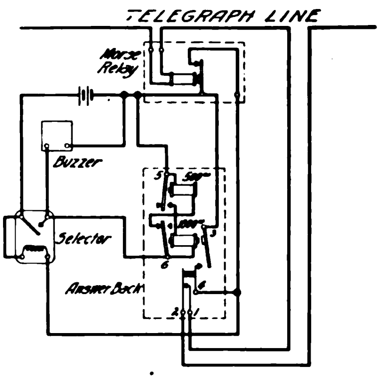

FIG. 6—TELEGRAPH SELECTOR ANSWER-BACK, TYPE A, FOR SINGLE MORSE CIRCUITS

message holder, from which messages can be reached from both sides of a quartette operating table. Each division of it has a designation card for some outlying office.

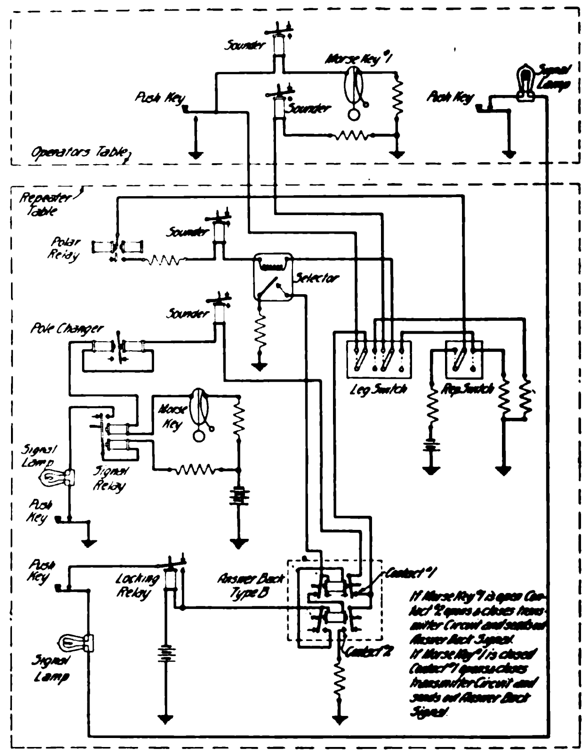

FIG. 7—TELEGRAPH SELECTOR ANSWER-BACK, TYPE B, FOR DUPLEX AND QUAD USE

TELEGRAPH SELECTOR AND ANSWER-BACK

The telegraph selector has been a growing factor in railroad telegraph traffic in recent years, until it is now considered an essential part of a modern relay office and is growing in favor for way-station use. It is quite generally used in conjunction with the lamp

signal concentration unit operating table for signaling offices. When the selector is operated by the distant station sending the proper code of impulses on the wire, it lights a lamp in the concentration unit. In concentration units many Morse wires are available to one or more positions of an operating table. Means of notifying the calling office that the selector had functioned was lacking until the telegraph selector answer-back of Fig. 6 was produced by the railroad. The fundamental idea is to cause the telegraph circuit to open and close at a speed corresponding to rapid dots,

FIG. 8—TELEGRAPH SELECTOR CALL CARD

which begin when the selector contact closes and continue until some one along the line opens the circuit; that is, the selector answer-back is under the control of any station. The two coils of the answer-back operate alternately to produce the speed of vibration desired at line contacts 1 and 2. Contacts 3 and 4 maintain the selector circuit closed while the Morse relay contact is released, which occurs when 1 and 2 open. The answer-back is also applied to duplexes as shown in Fig. 7 and will give a signal whether the key at the selector station is open or closed. The selector is operated in the local sounder circuit of the polar relay and the answer-back opens and closes the transmitter local sounder circuit to send the signals to the calling station. This device on either single line or duplex gives operators considerable satisfaction in knowing they waste no time in calling, and it promotes efficiency of service. The card sent out to notify stations of the combination and method of making it is shown in Fig. 8. The selector combination is placed on this with a rubber stamp, because, generally, only two or three score are needed and individual printing cannot be justified. It is found that the signal is easier to make with the combination printed in a vertical column, with one group of impulses below the other, than with the whole combination strung out in one line. At smaller offices where more than one selector is used but no lamp signal concentration unit is provided, a special design of visual signal box based on the railroad's design is used.

One of the best examples of the value of the telegraph selector is on the New York Central Lines on a telegraph train report wire extending from New York to Chicago and known as the "GX" wire. The wire is used for reporting the time that through passenger trains pass the several important points, to the recorder's office at New York. This office has a keyboard with Gill selector keys about the same as on a telephone train dispatching circuit. The selectors are distributed from New York to Chicago. The circuit has six sets of telegraph repeaters, which gave trouble in adjustment until the Chicago end was equipped with a selector and answer-back. This gives the recording office operator instant check on the repeater adjustment and continuity of the circuit. If he calls Chicago and gets the answer-back, it is evidence that the repeaters are fairly well lined up and that the circuit is unbroken.

RAILROAD SIMULTANEOUS TELEPHONY AND TELEGRAPHY

The railroad makes use of simultaneous telephony and telegraphy on practically all its wires, including station-to-station block telephone circuits, train dispatching circuits, message telephone circuits and long-distance lines. The station-to-station block telephone simplex is illustrated in Fig. 9 which indicates "single" Morse on the simplex, but this type of circuit is very successfully duplexed and has been quadruplexed with good results in some cases. This block telephone circuit is very seldom used in a phantom, because there is but one such circuit on any one pole line and this is looped in and out of every office, and further, being iron wire in nearly all cases, it would not give transmission up to the required standard, for the distances phantoms are required to cover in railroad service.

Dispatching and message telephone circuits are like Fig. 10 in general, if direct-current impulse selectors are used. This figure indicates the added resistance that is necessary with the simplex coils to prevent the coils short-circuiting the direct-current impulses which operate the telephone selectors. A phantom composited is shown such as are made up from dispatchers and message circuits on one railroad di-

vision. This figure without the composite equipment and without the condensers around the added resistance in the simplex coil bridges, illustrates an ordinary

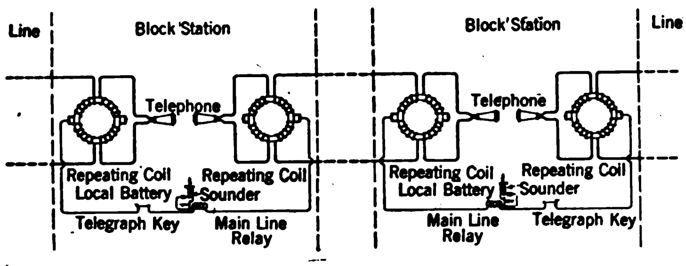

FIG. 9—STATION-TO-STATION BLOCK TELEPHONE SIMPLEX

high-resistance simplex. Straight Morse is shown but these are often duplexed in the service of the larger railroads to gét better service in weather that would reduce the margin of a single Morse circuit to an unsatisfactory degree. The dispatchers and message telephone circuits on each division with few exceptions are paired into a phantom by proper transpositions, and composited. In recent high-resistance phantom installations two separate repeating coils are used on each circuit at each end, one for the telephone tap and the other for the telegraph. The No. 5-AA retardation coil combines the two separate Morse leg coils in one unit, likewise combines the shunt retardation coils in one unit, each unit having two separate and distinct magnetic circuits with but one cover and base. If alternating-current selectors, which are alternate positive and negative impulse selectors, are used, a repeating coil scheme of sending the impulses can be employed, in which case the same coil is used for the Morse and phantom connection to the physical pairs as indicated in Fig. 11. This gives a low-resistance simplex, generally 1000 ohms or more below the ordinary "high-resistance" simplex of Fig. 10, assuming 150-mile lines of No. 9 A. W. G. copper wire. The composite ringer is used for signaling between the terminals on phantom circuits which are composited.

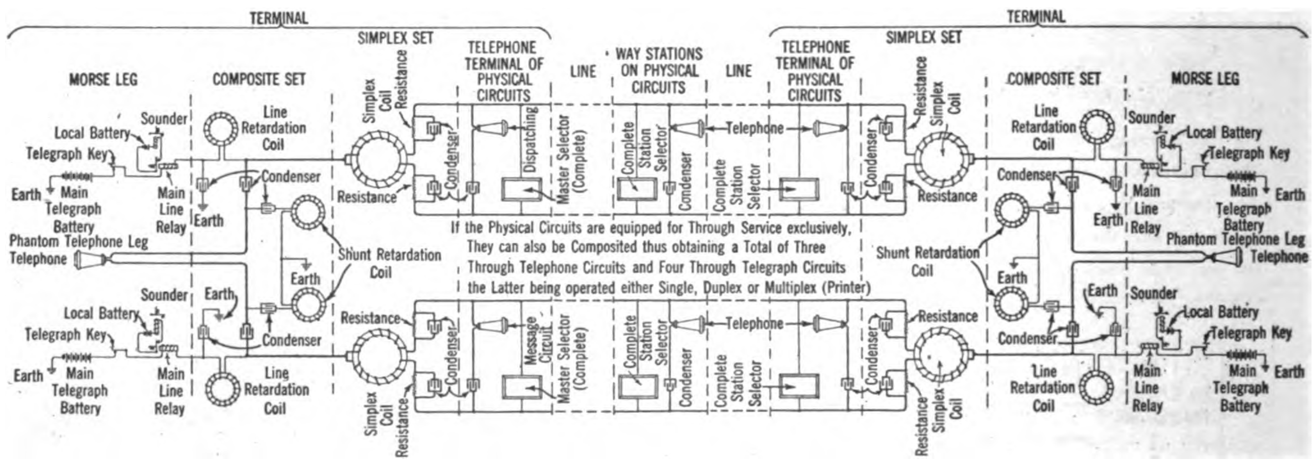

FIG. 10—HIGH-RESISTANCE SIMPLEXES WITH COMPOSITED PHANTOM

Long-distance telephone lines are simplexed if the transmission losses incident to the use of composite apparatus are prohibitive; also if there are any intermediate telephones, or if there is no need of additional telegraph sérvice. The railroads generally have no spare telegraph facilities and can use all they can get. The simplex can be single, duplex, or quadruplex. Two such circuits can be made up into a phantom without simplexing or compositing. This is frequently done in railroad service for trunk lines between outlying private branch exchanges and the main branch exchange. In some cases repeating coils are inserted in the phantom drop circuit and a Morse circuit connected to the middle of the line side, thus making a four-wire simplex telegraph circuit. This, in some cases, is done instead of compositing the phantom which would give two Morse circuits, in order to obviate composite ringers; in other cases it is to get more copper in the Morse circuit, for example when No. 19 A. W. G. cable conductors are used, in trunks between offices in metropolitan districts.

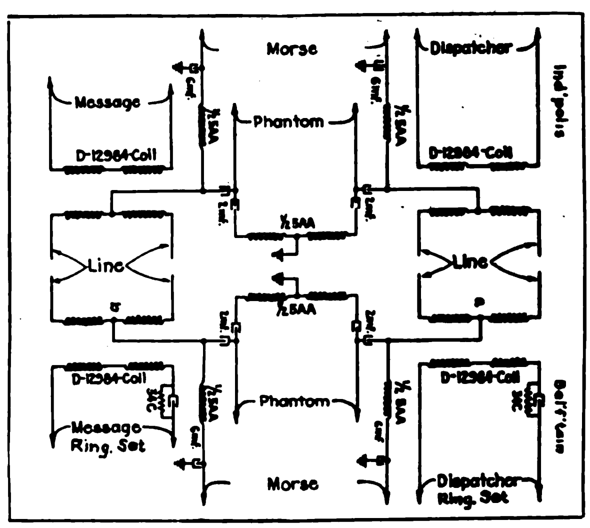

FIG. 11—LOW-RESISTANCE SIMPLEXES WITH COMPOSITED PHANTOM

If no intermediate stations are required on a long-distance line, and the transmission volume is ample,

the two wires of the pair are composited with which composite ringers are used and with Morse legs carrying either single or duplex telegraph. Two of these long-distance composited pairs can be phantomed if properly transposed.

Single wires for telegraph purposes only, are almost a thing of the past for railroad service along some of the large railroads. This is because of the economy in using all available wires for simultaneous telegraphy and telephony. Before the advent of telephone train dispatching there were very few long-distance telephone circuits. The New York-Chicago, New York Central No. 8 B. W. G. copper pair which was strung in 1904 was a notable exception. The division service on many trunk lines consisted of one iron Morse train wire, one iron message wire, and very rarely, an iron wire for station-to-station grounded telegraph block circuit. When a telephone dispatching copper pair was strung, resulted in complaints, some officials thinking the "connection was poor," when they were talking on the iron circuit. It was found that no circuit diagram was available for a combination of a composited pair and a simplexed pair for a phantom, and it was necessary to develop one by experiment. The result is shown in Fig. 12, which indicates that each side of the dispatching telephone line is treated as a composited wire; that is, there is one-half of a No. 5-A A retard coil in each wire. This was found necessary to give a quiet phantom terminal set. This type of circuit gave almost as good a phantom circuit as Fig. 10. The two retard coils in each end of the simplex did not reduce the speed of Morse service, because but half the telegraph current went through each. The capacity to ground on each side of the set at the retard coils was made three microfarads on the simplex and six microfarads on the composite. The equipment

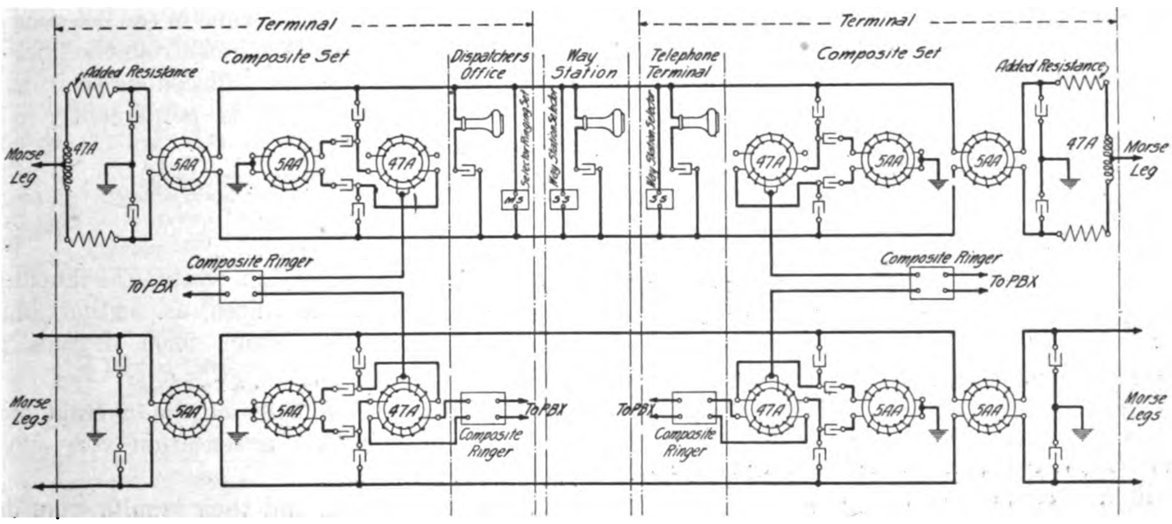

FIG. 12—TWO METALLIC TELEPHONE LINES WITH THROUGH PHANTOM, ONE PHYSICAL SIMPLEX, AND EQUIPPED FOR WAY-STATION TELEPHONE SERVICE, OTHER COMPOSITED THROUGH TELEPHONE LINE

the old train wire and message wire were generally paired and made into a station-to-station block telephone circuit and simplexed for the way-station Morse message wire. The addition of a message telephone copper pair at a later date completed the division service and provided a long-distance phantom circuit which was generally as much needed as the way-station message telephone pair. This leaves many divisions with no single wire—nothing but pairs, simplexed or composited for telegraph.

A phantom made up of one composited pair and one dispatching circuit was developed by the railroad for a special situation between Indianapolis and Cincinnati, which points were connected for long-distance service by one No. 8 B. W. G. iron composited long-distance line and one No. 9 A. W. G. copper phantom, the latter consisting of the dispatching and message circuits. The phantom gave much better transmission, and because calls for the same party were first on the iron circuit and next on the copper, it on the office side of the No. 5-A A coils has no effect on the circuit as far as phantom noise is concerned, which permits of the three microfarads on one circuit and six microfarads on the other.

EXTRA HIGH IMPEDANCE TELEPHONES

In arranging for the simplex-composite phantom, it was necessary to use the iron wire circuit as a way-station message telephone circuit, and use the copper pair formerly in this way-station service, as the composited pair of the phantom. This would not have been possible but for a recent advance in telephone transmission which resulted from the use of extra high impedance telephones. The improvement in telephones was the result of experiments made necessary by the emergency use of a one-hundred-mile No. 8 B. W. G. iron wire circuit as a dispatching circuit, in order to divide two dispatching districts into three parts for handling unusually heavy freight traffic that existed just previous to the entrance of the United States into the war. No means of calling stations was

provided on this circuit, so that all stations continuously listened in. There were 30 of them, and the resultant "listening" losses were so great that stations at one end of the line could not hear those at the other end. This gave the clue to the cause of other transmission troubles, which were that at certain periods of the day, transmission on dispatching circuits was excellent and at other periods it was very poor. The evidence now is plain that in the evening hours, when

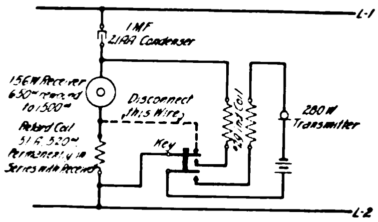

FIG. 13—295-AK AND 300-W SUBSETS CONVERTED TO EXTRA HIGH IMPEDANCE TELEPHONE BY USE OF 1500-OHM RECEIVER

the transmission was poor, many operators were listening in. At other times, particularly in the morning hours, transmission was good because the operators were busy with other duties and had the receivers on the hooks.

The outcome of the investigation was the use of 1500-ohm receivers with a retard coil permanently in series as shown in Fig. 13. It was found that with these sets, all stations on the hundred-mile iron wire circuit could listen in simultaneously without noticeable diminution of transmission. The results on dispatching copper circuits, especially the ones with a large number of stations, were likewise gratifying. Some of these dispatching circuits have 60 to 65 stations, whereas the average over the country is but thirty, and the telephones previously in use, with 650-ohm receivers, were designed for a maximum of about 15 receivers off the hook at once. The 1500-ohm receiver is equally effective on the Wray-Cummings "booster" telephone, which also has a retard coil permanently in series with the receiver. The Western Electric Company had developed an extra high impedance set with a repeating coil and 70-ohm receiver, which was about ready to put on the market and which was put out very shortly thereafter. This gives the benefit of high impedance when in the listening position and also insulates the telephone from the line. In this set the repeating coil is not disconnected from the line by the hook-switch but is permanently connected across the line.

(To be continued)

DETERMINATION OF THE STANDARD FOR "WHITE LIGHT"

The definition of "white light" naturally constitutes a very important part of the scientific foundation of colorimetry. If we consider incandescent light sources generally (including oil and gas flames; carbon and metallic filament electric lamps) we find that the light from sources at comparatively low temperatures evokes reddish or yellowish colors. As the temperature of the source increases, the color becomes paler and paler yellow and, at higher temperatures, approximates to "white." However, all artificial incandescent sources are decidedly yellow in comparison with sunlight, since it is not possible to operate an artificial source at a sufficiently high temperature to color-match sunlight. We are led to anticipate, however, that a source at a sufficiently high temperature would color-match sunlight, and further that sources of still higher temperatures would appear blue relative to the sun. The question arises as a matter of physiological optics, at what temperature would a source appear under standard conditions of observation neither blue nor yellow but white. The further question then arises relative to this standard, is the sun blue, yellow or white? Recent experiments made at the Bureau of Standards, Washington, D. C., answer these questions in so far as four observers are concerned. They are the first accurate experiments of this nature ever performed. The answers are:

1. Theoretical. The temperature which a hypothetical source would have in order that its light might evoke the sensation white (the hueless sensation of brilliance recognized as neither bluish nor yellowish) would be about 5200 degrees absolute Centigrade.

2. Practical. The light of the average noon sun at Washington evokes a sensation very closely approximating white.

These experiments and their results were described at a joint meeting of the American Physical Society and the Optics Society of America in Chicago, December 29, 1920. It is expected that they will be described in detail in a forthcoming publication of the Bureau of Standards and persons desiring further information should address such request to this Bureau, attention of Division 4, section 3.

TESTS OF AUTOMOTIVE FUELS

Tests are being carried out at the Bureau of Standards on special blended fuels at the request of other government departments. Conferences have been held with members of the Fuel Research Committee of the Society of Automotive Engineers and other organizations, including representatives of the government, looking toward the formation of a definite program for the investigation of various fuel problems of interest in connection with automotive engineering practise. During a recent visit of one of the members of the Bureau's staff to Europe a special study was made of fuel conditions abroad.

Developments in Conversion Apparatus for Edison Systems

BY T. F. BARTON and T. T. HAMBLETON
Both of the General Electric Co.

ELECTRICAL energy for Edison systems is most efficiently produced and distributed to substations in the form of alternating current. At the substation it is converted into direct current and distributed to a three-wire network at a suitable voltage.

Conversion apparatus for Edison systems has taken the form of motor-generator set, synchronous converter and dynarotor. The voltage-range requirement of this service caused the development of several schemes for effecting voltage range with a synchronous converter. The tap changing switch with the transformer, the induction regulator, the regulating pole construction, the synchronous booster and field control are the forms which have been or are in commercial use.

Edison systems operating at 25 cycles have used synchronous converters almost entirely. At 60 cycles the motor-generator set, both synchronous and induction has been used extensively on account of the questionable performance of the early 60-cycle converter.

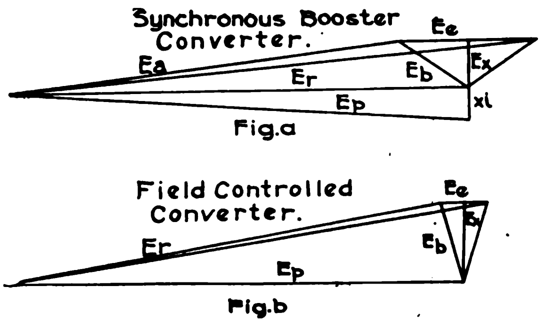

FIG. 1—VECTOR DIAGRAMS, SYNCHRONOUS BOOSTER AND FIELD-CONTROLLED CONVERTER

Conversion apparatus for Edison systems must provide sufficient voltage range to maintain constant voltage at the load centers. The range depends on the amount of copper in the feeders and network, location of substations and load density.

In order to present the facts which should be considered in selecting the more suitable type of conversion apparatus for a particular service, the characteristics of the synchronous converter and the modern motor-generator set will be discussed.

SYNCHRONOUS BOOSTER CONVERTER

The synchronous booster has superseded the induction regulator because of lower first cost, greater reliability, and simpler substation layout. Its characteristics will be considered in detail for comparison with other types.

Fig. 1*a* represents vectorially the relation of the voltages in the converter, booster and transformer at full load. For simplicity, the resistance drops have been omitted. Unity power factor is assumed at the collector rings. The following table specifies and gives the values of the voltages.

E_R	—Collector ring voltage	100
E_x	—Booster reactance voltage from load current	10
E_e	—Booster energy or field voltage	15
E_b	—Booster armature voltage	18
E_a	—Converter armature voltage	85 or 115
$x\,i$	—Reactance drop in transformer and leads.	7.5
E_p	—Primary voltage	100. +

The principal component of E_x, the reactance voltage of the booster, is generated by the armature conductors cutting a magnetic field set up by the armature reaction of the load current in the neutral space and adjacent pole tips. It is 65 to 70 per cent of the designed voltage of the average booster.

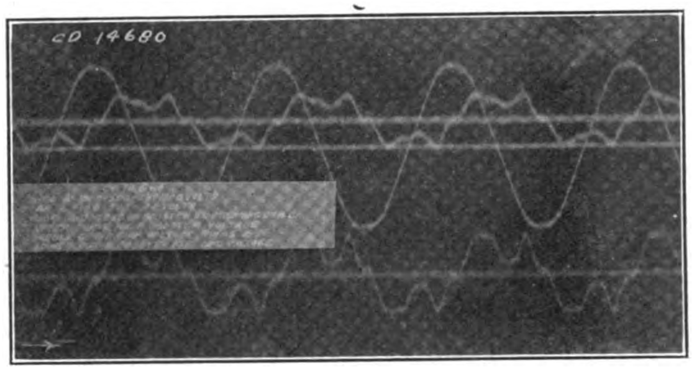

FIG. 2—OSCILLOGRAPH RECORD, 1000-KW., 25-CYCLE SYNCHRONOUS BOOSTER CONVERTER

Uper curve—Collector ring voltage
Middle curve—Booster armature voltage
Lower curve—Booster armature exploring coil voltage

Fig. 2 is an oscillograph record showing the voltage at the collector rings, voltage of booster armature and of an exploring coil in the booster armature. The latter indicates the field form of the flux set up by the armature reaction. Such a field form will cause high core loss and eddy current loss in the armature conductors. The eddy current loss is materially reduced by the use of stranded cable conductors in which the individual strands are adequately insulated.

The power factor at any point in the circuit can be determined from the relations shown in Fig. 1*a*. For unity at the collector rings the converter is furnishing

To be presented at the 368th Meeting of the A. I. E. E., New York, March 11, 1921.

10 per cent leading kv-a. (99.4 power factor). For unity at the primary terminals of the transformer, the converter armature must furnish leading kv-a. to the amount of 10 per cent for the booster reactance, 7½ per cent for the transformer and lead reactance, and 5 per cent transformer magnetizing current,—totaling 22½ per cent (97.5 power factor).

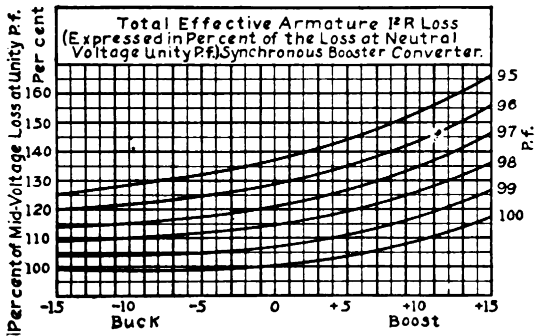

FIG. 3

The values here assigned to reactance and magnetizing current are a minimum for modern designs; therefore, combinations, especially at 60 cycles, will be found where the converter armature must operate as low as 95 per cent power factor leading to hold unity at the transformer primary.

Fig. 3 shows the effect of power factor and booster on the average $I^2 R$ loss of the armature conductors. Fig. 4 shows the effect on the $I^2 R$ loss in the armature conductors in the tap zone. The tap zone includes the armature conductors in which the greatest average $I^2 R$ loss occurs and is therefore the hottest spot in the converter armature. It is here taken as the tap slot and the adjacent slots on either side. The greatest loss occurs in the tap coil at unity power factor. The greatest average loss at any leading power factor takes place in the conductors in the slot next ahead of or in the direction of rotation from the tap slot. The converse is true for lagging power factor.

The $I^2 R$ loss in the tap zone of a converter increases at a much greater rate for a change in power factor than in any other type of alternating-current machine. It is, therefore, of the greatest importance that a converter be operated within the power factor limits for which it has been designed.

The transformer capacity is usually 5 to 10 per cent greater than the converter. The high-voltage winding is arranged with four 2½ per cent full-capacity taps below rated voltage. The low-voltage winding is provided with a 50 per cent tap for connecting to the neutral of the Edison system. Suitable taps and lead arrangement are provided in either winding if a-c. starting is required.

The reactance and exciting current are a minimum consistent with conservative transformer design. An upper limit of 7½ per cent for each is set for continuous rated machines. The rated secondary voltage should be as high as the range of the booster, together with the application requirements, permits, for such an arrangement gives the best efficiency, lowest heating and most stable operation.

In the simple converter there is a fixed relation between the direct and alternating currents. The resultant armature reaction under the commutating pole, therefore, varies directly with the load current and may be neutralized by a series winding. This relation exists also in the synchronous booster converter when the booster field is not excited. The series winding alone maintains commutation at the mid or neutral voltage.

When raising or lowering the voltage, the booster operates as an alternator or motor; the converter as converter and motor or as converter and d-c. generator. The armature reaction of the motor current in the converter armature magnetizes, and, of the generator current, demagnetizes the commutating pole. To maintain correct commutation, these effects must be neutralized. This is accomplished by a second winding on the commutating pole properly excited and controlled. This winding, in the case of a 15 per cent booster, is approximately 40 per cent of the series winding. Its control, therefore, must be accurate and reliable.

FIELD-CONTROLLED CONVERTER

The field-controlled converter was developed to meet the need of a limited voltage range machine.

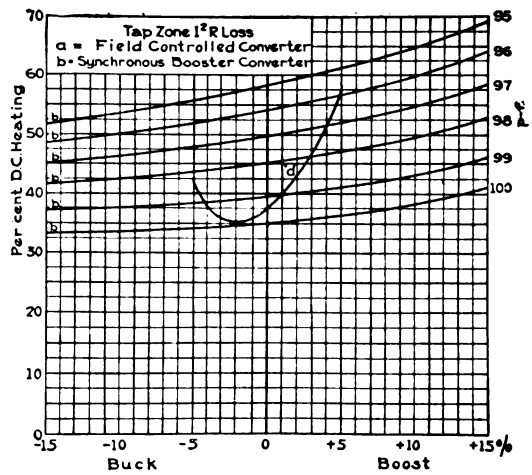

FIG. 4

The voltage range of certain buses in large substations is small although the range of substation voltage is large.

Fig. 1*b* represents vectorially the relation of the voltages in the converter, reactance and transformer at full load. The resistance drops are omitted as in Fig. 1*a*. Unity power factor is assumed at the transformer primary. The following table designates and gives the value of these voltages:

E_p	—primary voltage	100
E_x	—reactance drop from load current	17½
E_e	—energy voltage of reactance	5
E_r	—converter ring or armature voltage	95 or 105
E_b	—total reactance voltage	18.2

It is evident from a comparison of the two figures that the total reactance of each type of equipment is approximately the same.

Fig. 12 shows the inherent regulation of synchronous booster and field-controlled converters for several equal voltage ranges. For the synchronous booster type 7½ per cent reactance is assumed for transformer and low-voltage connections. For the field-controlled converter 2½ per cent is assumed for the low-voltage connections (60 cycles may be 3½ to 5 per cent) and the additional reactance in the transformer required for the several voltage ranges.

It should be noted that the inherent regulation of the 5 per cent field-controlled converter is no greater than the 5 per cent synchronous booster converter. Slightly different assumptions of reactance and resistance would make little change in the results.

The voltage range determines the amount of reactance and reactive current, and the converter is designed to carry this current at full load. At fractional loads, it may be increased, with a corresponding increase in the voltage range without exceeding full-load armature heating. Fig. 5 shows additional marking on a d-c. ammeter scale to indicate the maximum reactive kv-a. permissible at any load.

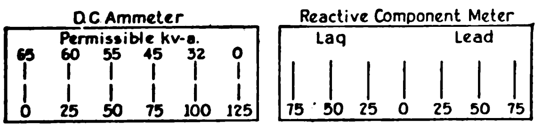

FIG. 5—MARKING OF D-C. AMMETER SCALE TO SHOW THE OPERATOR THE CAPACITY OF THE CONVERTER

The field-controlled converter at unity power factor is a simple converter and the commutation requirements are as previously described. When the power factor is leading, there is a change in the armature reaction which demagnetizes the commutating pole; the converse is true for lagging power factor. To neutralize this effect, a second winding is required on the commutating pole. This winding is approximately 10 per cent of the series winding on a converter of average proportion used for a 5 per cent voltage range by field control. The disturbance in the armature reaction is proportional to the reactive current which, in turn, is proportional to the main field current. The second winding is, therefore, excited and controlled from the main field rheostat.

The shunt-wound converter can be operated with equal stability over a greater range of reactive current and with more reactance in the a-c. circuit than the compound-wound machine. The usual design of 250-volt converter gives about 50 per cent reactive current at no-load and with zero field. To get the best efficiency over the voltage range, maximum obtainable reactive current is used at no-load minimum

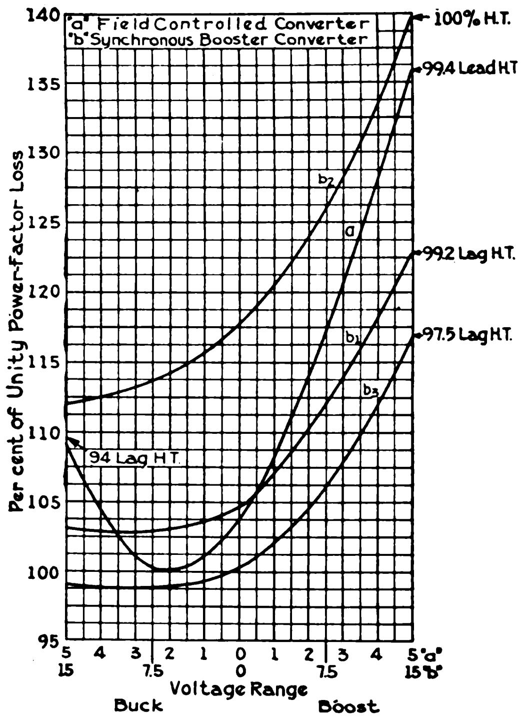

FIG. 6—COMPARISON OF $I^2 R$ ARMATURE LOSSES OVER THE VOLTAGE RANGE OF THE FIELD-CONTROLLED AND THE SYNCHRONOUS BOOSTER CONVERTER WITH UNITY POWER FACTOR, HIGH-TENSION COLLECTOR RINGS AND CONVERTER ARMATURE

voltage. The converter armature loss on this basis, over a 10 per cent voltage range, is shown in Fig. 6, Curve *a*.

Fig. 7 gives results from test showing the relation of reactive current at the converter collector rings at no-load, half load, and full load over the voltage range. The loss shown in Fig. 6, Curve *a* is based on results of test.

Fig. 8 shows the conventional voltage range, that is,

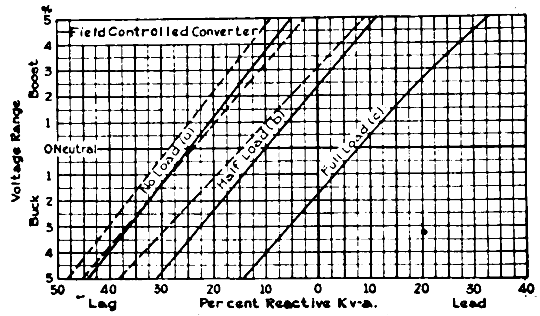

FIG. 7—RELATION OF VOLTAGE RANGE TO REACTIVE KV-A.—4200-KW. 25-CYCLE FIELD-CONTROLLED CONVERTER

the range from no-load minimum to full-load maximum; also the additional range at lower voltages with increase in load, and the additional range at higher voltages with partial loads. The curves are from test

on a 4200-kw. unit. It may be argued that only the conventional range is of any commercial value, but additional lowering of voltage under load is useful for load shifting and limiting. The higher voltage will often provide for the requirement of a higher bus on which the load is small.

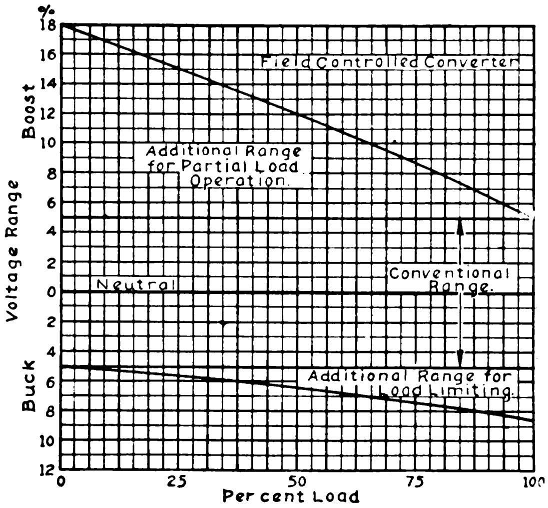

FIG. 8—RELATION OF VOLTAGE RANGE TO LOAD—4200-KW. 25-CYCLE FIELD-CONTROLLED CONVERTER

In the larger substations, three d-c. buses are often used. During light load periods, all buses are tied together, giving in effect, a 24-hour load at nearly constant voltage. (Fig. 9 low bus).

The voltage of the main and high bus is also shown. Attention is called to the voltage range indicated by x and y. This is an important consideration where a

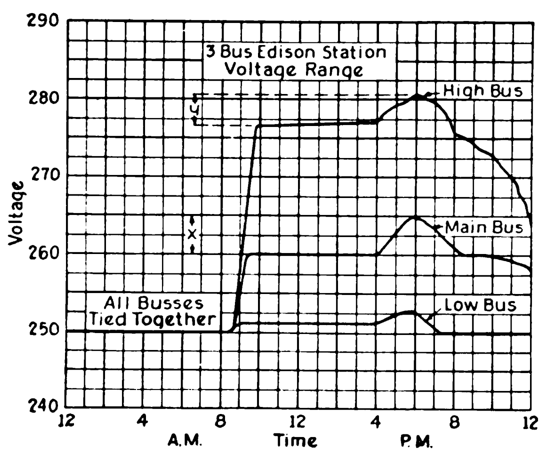

FIG. 9

number of machines are operating in parallel on a bus. The wide-range machines are connected first and the narrow-range machines are connected last and disconnected first. Suitable switches for changing the transformer connections with the transformer unexcited makes a narrow-range machine available for any bus. To change from one bus to another, the load must be removed, the transformer line switch opened, ratio adjuster operated to the desired position, machine synchronized, and loaded.

The transformer is designed for approximately 15 per cent reactance. The equipment is designed for a total range of 20 per cent (± 10 per cent) with five running points on the transformer. The available range

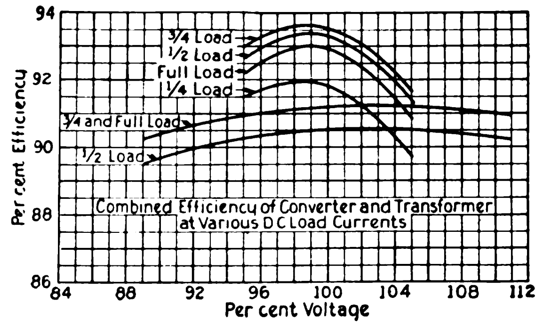

FIG. 10—COMBINED EFFICIENCY OF CONVERTER AND TRANSFORMER

Upper 10 per cent voltage range curves, 4200-kw. 25-cycle field-controlled converter equipment.

Lower 22 per cent voltage range curves, 3500-kw. 25-cycle synchronous booster converter equipment

from any running connection is 10 per cent (± 5 per cent) resulting in a very flexible arrangement. The high-reactance transformer is a very satisfactory design, and, in many cases, costs little more than the low or normal-reactance type.

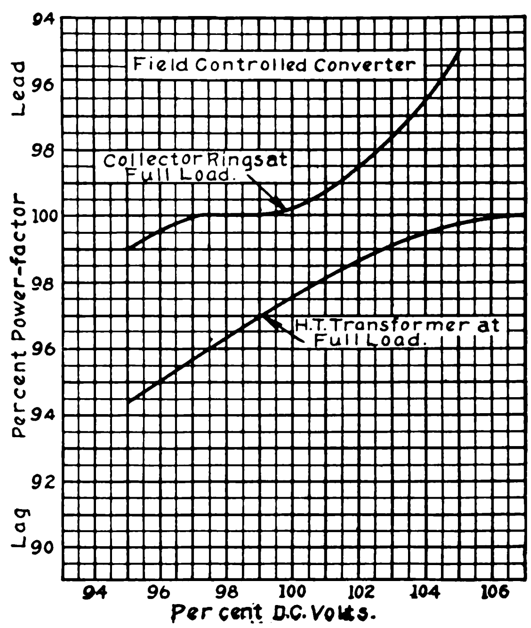

FIG. 11—RELATION OF POWER FACTOR TO VOLTAGE RANGE AT FULL LOAD, FIELD-CONTROLLED CONVERTER

The following is a comparison of the field-controlled and synchronous booster types:

1. Higher efficiency of field-controlled type as shown in Fig. 10. The values are from tests on a 4200-kw. field-controlled and 3500-kw. synchronous booster converter and transformer. The transformer efficiency

in each case is approximately the same and the loss in the low-voltage connections has been deducted. The efficiency of the types over their respective voltage ranges is shown at one-half, three-quarter and full load. The efficiency of the field-controlled converter varies considerably over the voltage range. A transformer connection should be chosen to give highest efficiency at the operating voltage.

Designing the synchronous booster converter for the same range as the field-controlled converter gives but slight improvement in efficiency because the losses in a synchronous booster do not decrease in proportion to the reduction in range.

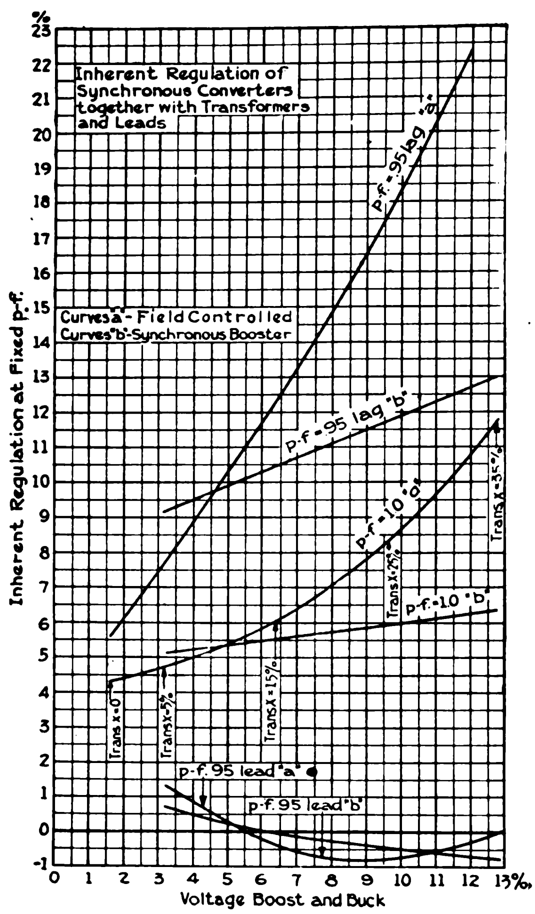

FIG. 12—INHERENT REGULATION OF CONVERTER EQUIPMENTS DESIGNED FOR SEVERAL VOLTAGE RANGES

2. Successful commutation over the voltage and load range of the field-controlled converter is obtained without the use of relays or special rheostats.

3. Better ventilation and accessibility of the field controlled converter.

4. Cost is in favor of the field-controlled converter for a voltage range not to exceed 10 per cent (± 5 per cent). The cost of the synchronous booster converter is reduced about 1 per cent in lowering the booster voltage from 15 to 10 per cent, and 2 per cent in reducing from 15 to 5 per cent.

5. Saving in floor space is in favor of the field-controlled converter.

6. The synchronous booster converter allows operating at unity power factor at the collector rings over its range of voltage; also it can be designed, at additional cost, to hold unity power factor at the transformer primary. The power factor of the field-controlled converter can not be adjusted independently of voltage, and the power factor at the transformer primary may be as low as 94 per cent lagging at full load minimum voltage, and about unity at maximum voltage. At partial loads the power factor will be lower; however, the reactive kv-a. should be considered, as it is a better guide than power factor. Fig. 11 shows the power factor at the transformer primary and the collector rings at full load over the voltage range.

7. The synchronous booster converter can be designed for a large voltage range while the field-controlled is limited to approximately 10 per cent. If the a-c. line has poor regulation (resistance drop) or is

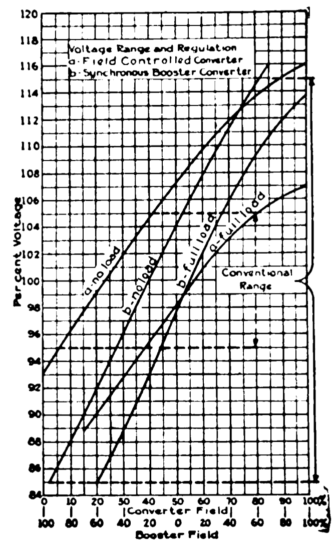

FIG. 13

subject to voltage fluctuations, the net range is reduced in proportion. The a-c. range should, therefore be considered in connection with d-c. range required, in selecting the proper type of apparatus.

8. When starting d-c., it is not possible to change the a-c. voltage of the field-controlled converter for synchronizing and the d-c. supply should be tripped immediately before closing the a-c. circuit. This method of synchronizing is desirable on the synchronous booster converter as well.

9. Simplicity of the field-controlled converter.

10. Fig. 13 shows voltage range and regulation from test on large units of each type. Close regulation is not necessary to meet requirements of Edison service, furthermore broad regulation, especially when batteries are floated on the bus, gives greater stability.

11. Fig. 6 shows the average I^2R loss in the converter armature of each type.

MODIFIED SYNCHRONOUS BOOSTER CONVERTER

The synchronous booster may be excited either by direct current in the field coils or reactive current in the armature. The field winding may, therefore, be

omitted and the field structure somewhat reduced. It is not practicable to furnish as much excitation through the armature as through the field windings and therefore this type of booster has a smaller voltage range.

The effects on commutation of the synchronous booster and field control are approximately equal and opposite for machines of equal range. Both these effects are present in the modified booster and no auxiliary commutation devices are necessary.

Transformers

Transformers for synchronous converters may be single- or three-phase, shell or core type, air-blast, water-cooled, or self-cooled.

The secondary winding is designed for low voltage with high amperage. This requires a winding consisting either of a large number of multiple coils or a helical winding containing many individual multiple strands. The first case requires multiple connections between coils and between coil groups; also provision for obtaining equal current division anong the circuits. The second case combines mechanical difficulties of coil support and of winding. A new type of coil has been developed and is now in commercial service that is well suited to large units at 25 cycles. Some 4550-kv-a. shell-type, air-blast transformers with 150 per cent load for two hours have been built using solid copper bar 7/16 in. (1.11 cm.) thick by 13 1/2 in. (34.3 cm.) wide for the low-voltage winding. This type of winding has the advantage of ideal mechanical construction, no danger from unsupported turns or strands, coils supported and braced with straight moulded channels and spacers, efficient cooling with air in direct contact with copper, small air-duct requirement, and improved space factor. There is the disadvantage of additional eddy current loss. The full-load efficiency of the 4550-kv-a. unit is 98.14 per cent. Fig. 26 is an illustration of the solid bar coil.

At 60 cycles, it is often desirable on large machines to provide twelve conductors between transformer and converter so as to obtain low reactance and uniform heating. Careful consideration should be given to the location of the transformer so that the low-voltage connections are short and properly arranged to give minimum losses. The transformer may be placed below the converter. For the minimum length of low-voltage connections the air-blast transformer can be placed immediately below the converter on its side to simplify the problem of ventilation.

Dynarotor

Low-voltage connections between transformers and converters are costly in large size units, and considerable loss and reactance are found in many cases. The motor generator has the advantage in this respect. Going a step forward, the motor and generator can be combined into one machine using a common armature core; and going a step backward with the synchronous converter, the direct and alternating current may be carried by two separate windings in a common core. The a-c. winding may be designed for the voltage of the bus not to exceed 13,200 to which it is connected through a suitable collector. The d-c. winding connects to a commutator. By providing a leakage path for flux between the two windings, reactance is obtained, and voltage range is obtained as

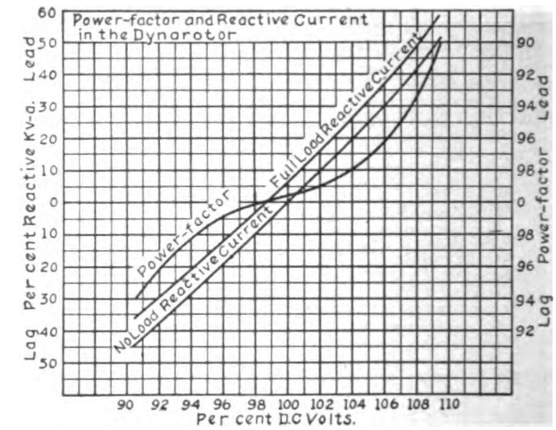

Fig. 14

in the field-controlled converter. The commutating-pole field strength is effected and compensated for as in the field-controlled converter.

There are certain apparent limitations due entirely to the usual forms of construction. The high-voltage a-c. winding is difficult when built on a rotor, especially if the voltage exceeds 6600. Since the a-c. and d-c. windings are in common slots, a failure in the bottom winding involves removing both windings for repairs.

The over-all efficiency of such a unit is slightly

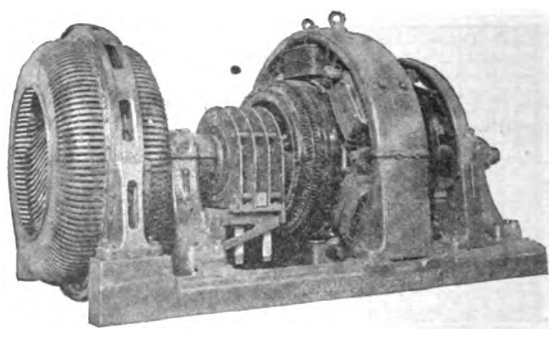

Fig. 15—1000-kw. 6600-Volt Three-Phase 250-Volt D-C. 25-Cycle Dynarotor with Synchronous A-C. Booster

higher than the synchronous booster converter with its transformer and connections, higher than the motor-generator, but lower than the field-controlled converter and transformer.

Fig. 14 gives characteristic curves from actual test on a 1000-kw. 250-volt unit. Fig. 15 is an illustration of the unit with a-c. synchronous booster. The booster was removed before the machine was installed since the necessary voltage range was obtained without it.

A-C. Starting

There have been no recent important developments in direct-current, induction-motor or secondary-tap starting. High-tension starting simplifies the low-voltage connections and eliminates heavy current switches.

Three methods are available: series-multiple, *Y*-delta and extended primary windings. Series-multiple offers the greatest advantage on two-phase-six-phase transformation; *Y*-delta on three-phase-six-phase, and extended-primary windings in conjunction with reactors for switching under load.

Y-delta is the cheapest. It requires two triple-pole switches only when 58 per cent starting voltage is suitable. For other voltages three primary taps must be added. The connections should be so chosen that the time phase displacement of 30 electrical degrees between the *Y* and delta connections will allow the converter armature to drop back a certain angle depending on the ratio of its losses to stored energy. This reduces the 30-degree phase displacement.

The starting kv-a. will be the same with low-tension or high-tension starting. The kv-a. on switching to full voltage depends on the voltage and phase difference of supply and converter. If the time in switching were zero, then the low-tension starting would have the advantage with no phase displacement against 30 degrees for *Y*-delta. The time in switching tends to equalize this difference.

Fig. 16 is an oscillograph record of the current in starting and switching, for secondary-tap starting, on a 2500-kw., 60-cycle, synchronous booster converter. The kv-a. at the instant of start is 150 per cent, dropping immediately to 110 per cent. On switching to full voltage, the inrush is 110 per cent. As a matter of interest, the complete starting and switching event is shown.

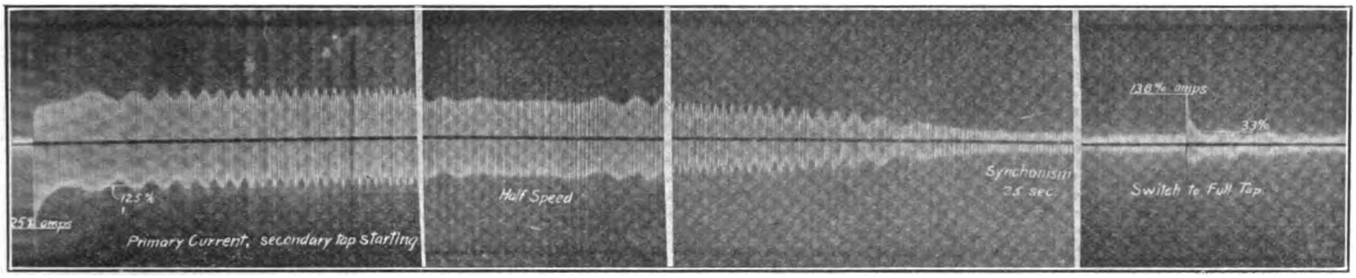

Fig. 16—Oscillograph Record, Secondary-Tap Starting, 2500-kw. 60-Cycle Synchronous Booster Converter

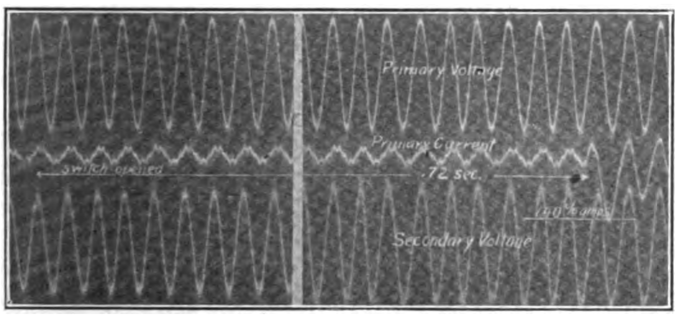

Fig. 17—Oscillograph Record, Secondary-Tap Starting, 2500-kw. 60-Cycle Synchronous Booster Converter
Switching from 75 per cent tap to full voltage

Fig. 17 shows the time of switching (0.72 sec.), also the phase displacement between line and converter, amounting to 20 electrical degrees behind.

Fig. 18 is an oscillograph record of starting current, for *Y*-delta high-tension starting, on a 3700-kw., 60-cycle, booster converter. The inrush kv-a. is 100 per cent, dropping immediately to 69 per cent. The inrush on switching to full voltage is 75 per cent.

Fig. 19 shows the time of switching (0.38 sec.), also the phase displacement between line and converter amounting to 20 electrical degrees ahead.

Fig. 20 shows that there is no noticeable effect on the voltage of the system (140,000-kv-a. connected capacity) when a 3700-kw. 60-cycle unit is started.

Motor-Generator

In selecting between synchronous motor-generator or synchronous converter for Edison service, costs, floor space, efficiency, parallel operation with existing apparatus, and synchronous condenser capacity have been the determining factors. The characteristics of the two types of apparatus are, however, radically different under certain conditions. The converter once out of synchronism with the supply can not remain connected to the d-c. system because of its

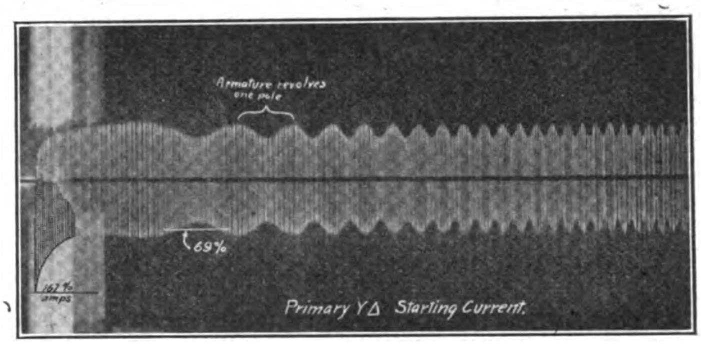

Fig. 18—Oscillograph Record, High-Tension *Y*-Delta Starting, 3700-kw. 60-Cycle Synchronous Booster Converter

changing polarity. The synchronous motor can drop out of step without affecting the generator in any way except to drop its speed and therefore its voltage and load.

Motor-generator sets now in operation on Edison systems have not been designed with special regard to load limiting of the generator or a-c. starting and synchronizing of the motor. Generators in the main have been built shunt-wound, a few compound-wound and a number with series windings for differential-genrateor or compound-wound motor operation. The differential generator was thought necessary for succesful parallel operation with batteries, but in actual practise it has been found that the regulation of the generator operating shunt-wound with series winding short-circuited is sufficient to give the desired results under normal conditions. Under abnormal conditions, however, it would be desirable to make use of this winding controlled so as to bring it into action on overload or reverse current to give increased stability.

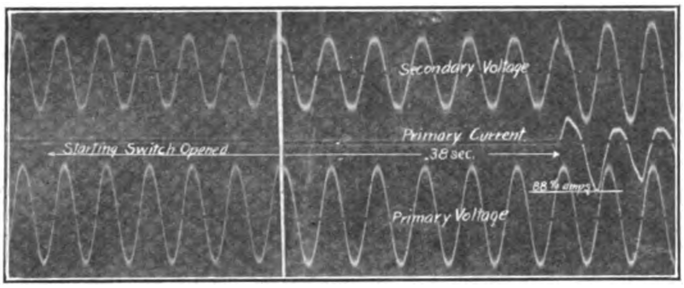

Fig. 19—Oscillograph Record, High-Tension Y-Delta Starting, 3700-kw. 60-Cycle Synchronous Booster Converter

Switching 72 per cent to full voltage

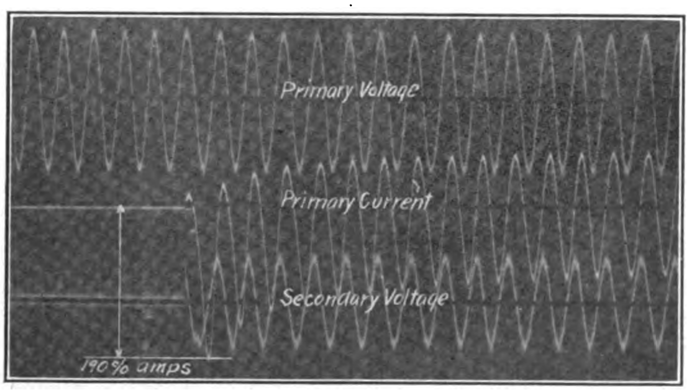

Fig. 20—Oscillograph Record, High-Tension Y-Delta Starting, 3700-kw. 60-Cycle Synchronous Booster Converter

Both generator and motor designs have advanced to the stage where certain desirable characteristics can be obtained at reasonable cost.

The synchronous motor can be designed to give sufficient torque to synchronize with full load on the generator. Figs. 21 and 22 show the relation between available motor torque and torque required by the generator, from which it is clear that the motor will synchronize with full load on generator if the supply voltage is normal. Reactance is connected in the motor circuit so that, in restoring service, full voltage may be impressed. The kv-a. required for starting with such an arrangement is high and would be warranted only under abnormal conditions. The usual switching arrangement with compensator would be used for normal starting duty.

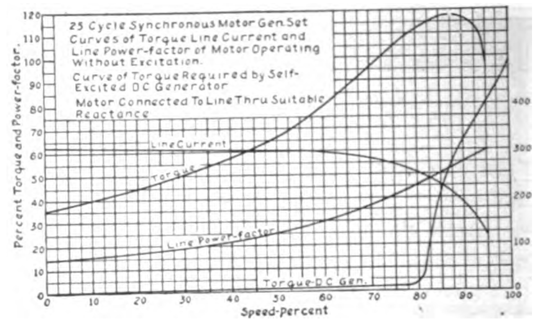

Fig. 21

The amount of reactance required for the 60-cycle motor would increase the cost of the set from 2 to 3 per cent, and lower the efficiency from 0.1 to 0.3 of one per cent. At 25 cycles, from 4 to 6 per cent in cost and 0.25 to 0.5 of one per cent in efficiency. The loss in the reactor under normal conditions could be eliminated by use of a short-circuiting switch, the switch controlled to open for or under abnormal conditions.

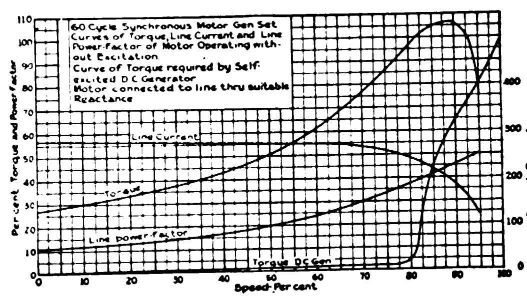

Fig. 22

The motor torque shown is that of the amortisseur winding. The motor field should be energized at about 95 per cent of synchronism, giving additional torque at the higher speeds, and finally synchronous torque. Below this speed, the torque would be greatly reduced if the field were excited.

The field circuit of the motor is controlled by a device that is responsive to "slip" between the motor and the supply; adjusted to open the motor field circuit at a predetermined slip and close it at a slightly higher value. This scheme makes available the maximum motor torque at all speeds.

The stator winding is protected against overheating by a thermal relay, the amortisseur winding by a time setting; that is, when the motor field is opened due to slip a time-delay relay will allow the motor to run as an induction motor for a definite time (probably three minutes.) If the motor field does not re-energize indicating synchronism, the time-delay relay will function to open the generator or motor connection to the line. The torque required at no-load is so small that any voltage that will start the set will bring it to synchronism. Also if the set is running at a voltage not sufficient to bring it to speed at no-load, the amortisseur winding will not overheat for a considerable period of time. If the motor field is re-energized in the predetermined time, then the time-delay relay resets and is ready for the next operation.

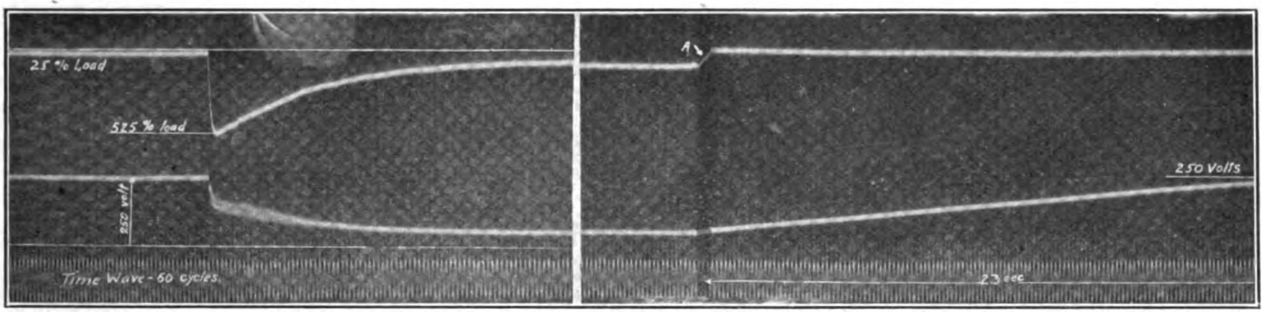

FIG. 23—OSCILLOGRAPH RECORD, SHORT-CIRCUIT TEST ON A 1000-KW. GENERATOR

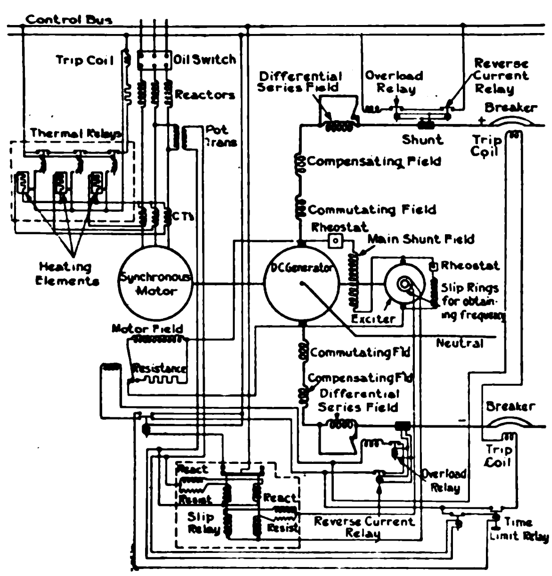

FIG. 24—SPECIAL CONNECTIONS OF SYNCHRONOUS MOTOR-GENERATOR SET FOR EDISON SERVICE

Disconnecting the generator, the motor, or both, from the line to protect the amortisseur winding of the motor gives a definite protection against dangerous heating. To insure synchronizing at voltages less than normal and thereby feeding the d-c. system all the available power an unloading control for the generator (not shown in Fig. 24) is used. A motor-operated rheostat of suitable resistance is connected in series with the shunt field of the generator and is controlled by a double acting instantaneous relay which is energized simultaneously with the time-delay relay used for disconnecting the generator from the line. This causes a lowering of voltage and current until the motor synchronizes. The speed of the rheostat is very slow so as to reduce the generator output a minimum amount for the motor to pull into step. With the closing of the motor field the unloading rheostat resistance is slowly cut out, giving normal field circuit resistance.

The generator characteristics can be made such as to limit its output in current, and withstand a short circuit at its terminals without flash-over. Fig. 23 shows an oscillograph record of current and voltage of a 1000-kw. 250-volt generator with connections as shown in Fig. 24.

This scheme of connections gives generator characteristics that limit its current output at any voltage from zero to normal that a system may require. The generator is arranged with a series winding that is connected in opposition to the shunt winding and normally short-circuited. The shunt winding is connected to the generator and exciter terminals connected in series. The generator is therefore, partly self- and partly separately-excited. The separate excitation gives stability and the self excitation and differential series excitation give elasticity to the system of voltage and current control. The separate excitation is balanced against the series differential excitation to give a limited output in current on short circuit (usually 125 per cent on continuous rated machines). Where generators are operated in parallel with batteries, exciters are not necessary.

Fig. 25 gives the characteristic curves of a generator with connections as shown in Fig. 24. Voltage in this case is automatically held constant up to full load, beyond which no further change is made in field rheostat setting. The short-circuiting device of the series differential winding opens, giving an initial drop in voltage and load. With a further reduction in resistance of the external circuit, the voltage gradually decreases to zero and the current increases

but slightly. This characteristic is required of a machine that is to be connected to an Edison system after a complete interruption of power (bus voltage zero).

Fig. 23 gives results as measured by oscillograph of a short circuit on the generator. The test simulates a short circuit on a d-c. system near the substation in which the generator is installed. The current increases to 525 per cent load instantly, then decreases to a constant value of 110 per cent load. The short

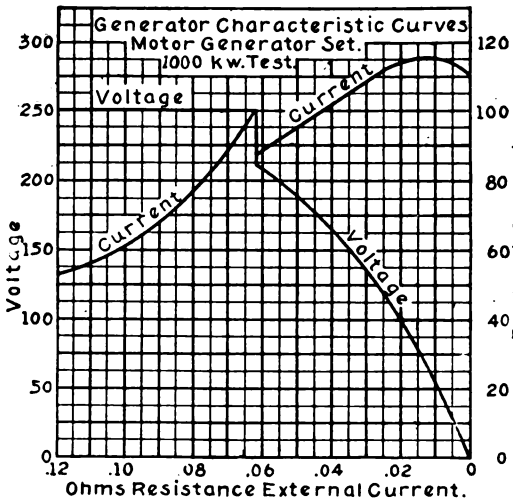

Fig. 25

circuit is removed at A. The current drops to zero and reverses. The generator operates as a compound-wound motor until voltage is restored approximately to normal.

The motor-generator with such characteristics will give continuity of service on an Edison system equal to that of the generating system supplying the power. The motor-generator, therefore, supplements the storage battery and can be used to reduce the amount of battery capacity required to give a system protection against a momentary interruption of a-c. supply.

Alternating-current power systems are constantly being developed to give continuity of service, also to localize the effects of disturbances and promptly to clear the fault from the system. Each improvement made in the a-c. system is reflected directly in the Edison system if the motor-generator is used. This does not mean that all conversion apparatus must be of the motor-generator type. A very careful study of any system will be necessary to indicate the proper capacity relation of converter, motor-generator, and storage battery to meet a desired service.

Restoring service on an Edison system after a complete shut-down is promptly and smoothly accomplished by the motor-generator set after the restoration of a-c. voltage. Each set connects to the d-c. system, delivers a predetermined amount of current and, as additional units connect, the voltage will increase until normal conditions are reached.

In general, the efficiency of the motor-generator at full load is approximately 2 per cent lower than the synchronous booster converter equipment, and at half load about 5 per cent. Floor space is about equal at 1500 kw., in favor of the motor-generator in smaller sizes and in favor of the converter in larger sizes. The difference is considerable at 4000 kw. The motor-generator is cheaper and more efficient as a three-unit set above 1500 kw. capacity. Generators controlled as shown in Fig. 24 can be connected permanently in parallel, which simplifies the switch-gear.

Automatic Substations

The advantages of automatic operation of substations for railway work have been fully demonstrated during the last six years, as is evidenced by the rapid increase in the number of such installations. Semi-automatic, remote control was demonstrated at Detroit in 1912 in the application of a 500-kw. synchronous converter equipment for lighting and power work. Edison systems to date have taken little or no advantage of developments for automatic control of conversion apparatus. The economy of the automatic substation for the interurban electric railway was obvious; its application to railway substations for city work was questioned and after six years, this

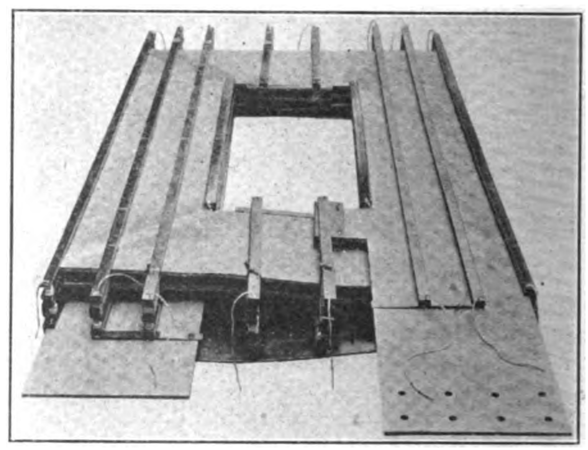

Fig. 26—215-Volt Secondary Coil and Insulation, 4550-kv-a. Air-Blast Transformer

field is being developed. The Edison substation differs but slightly from the latter, and, in the case of several moderate-size systems where a complete analysis has been made, the automatic operation of the entire system is not only favorable but highly desirable. In one case, it was necessary to vacate existing substations and change all converting apparatus to operate from 60 instead of 25 cycles. Here the a-c. system was developed and protected sufficiently to warrant the omission of batteries provided the automatic substation could be depended upon to handle the situation normally and under any emergency.

In another case, the main substation was located on very valuable property. By sub-dividing a saving

can be made in substation and property cost, in addition to a large saving in distribution losses and operating costs.

Every system has its specific problems. There are large substations located in high load-density areas where automatic operation is neither desirable, economical or advisable; there are stations where duties aside from operating would require attendance, but there is probably a place on every Edison system for an automatic substation.

The existing d-c. area may be encroached upon by the a-c. system because there is not enough load for an additional manually operated station, because feeder losses are high to the nearest d-c. substation, or because a booster or special machine would be required at the existing substation; yet d-c. service might be very desirable in such a locality. The automatic substation is the answer.

The operator who goes about his duties quickly, makes every move with precision and accuracy, is not confused by emergencies, exercises good judgment and is constantly alert to the situation, is too valuable a man for operating, and such insurance can be given the apparatus and service by automatic control. Confidence in the operation of automatic substations comes with experience in operating them.

The small and medium-size automatic substation would be provided with load-limiting equipment. In case of complete shut-down of the system the automatic substation starts promptly on the return of a-c. power, connects to the d-c. system and delivers its full current output, raising its voltage as the system permits until normal conditions are restored. For larger automatic substations, conversion apparatus with sufficient voltage range for load shifting when converters are used, and individual feeder protection by a suitable form of re-closing device, will be the most economical arrangement if the capacity of such automatic substations is not essential in restoring service after a complete system shut-down.

The automatic substation can at times be justified by the saving in operating costs, if converters are used and no-load limiting equipment is required. To secure the maximum return, however, the substations and distribution should be worked out to give a proper balance between cost of losses and capital investment.

No-load limiting equipment is required in the case of the motor-generator set as has been described. Also the motor can be designed to give motive power under all except the most abnormal conditions of power supply. This form of conversion apparatus is therefore very suitable for automatic substation application.

Load-limiting equipment for the converter is most economical in the form of series resistance. The type of resistor depends on the machine capacity and the number of steps required. In general, above 500 kw., water cooling is provided if resistance metal is used; metal resistance with suitable short-circuiting device if the number of steps does not exceed four and the current capacity does not exceed 19,000 amperes. A liquid rheostat with an infinite number of steps to the point of short-circuiting is used for higher capacities or more exacting requirements. Provision should be made to exhaust the vapors from the substation with either of the latter forms of resistors.

The authors desire to express their thanks to Mr. E. O. Shirley for help in preparing this article.

MAXIMUM ALLOWABLE WORKING VOLTAGES IN CABLES

Correction

In the article, "Maximum Allowable Working Voltages in Cables," by Davis and Simons, JOURNAL of the A. I. E. E., January, 1921, Fig. 2 on page 13 was incorrectly published, and a corrected Fig. 2 is shown herewith. The text of the article stated that the maximum stress in a three-conductor cable occurs at the surface of each conductor, and at that portion of the surface which is *nearest the center* of the cable. Fig. 2 was intended to illustrate this point, but unfortunately the arrows showing the location of the maximum stress were placed on the line of centers between conductors instead of at the points nearest the center of the cable, as correctly shown in the accompanying figure.

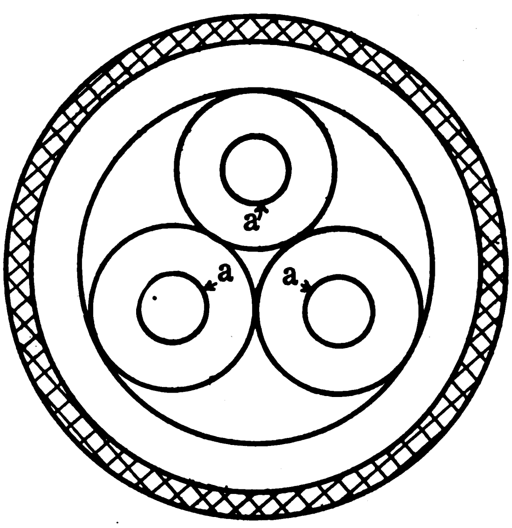

FIG. 2

(a) Shows location of maximum stress under three-phase voltage.

Longitudinal and Transverse Heat Flow in Slot-Wound Armature Coils

BY CARL J. FECHHEIMER

Research Engineer, Westinghouse Elec. & Mfg. Co.

It has long been recognized that the heat generated in embedded armature conductors by the I^2R and eddy current losses in part escapes by transverse flow through the insulation from the copper to the iron (possibly, to a more limited extent, to the air at the ducts) and in part flows longitudinally along the copper to the ends of the coils exposed to the cooling air. The importance of a solution of the combined transverse and longitudinal heat flows has been realized, for upon these the internal copper temperatures must necessarily be dependent. Thus, it has long been known that in a machine of short core length, the iron temperature and temperature at the center of the machine by detector between coil sides could usually be reduced by increasing the volume of air blown upon the ends, but in machines of long lengths (say 50 inches or more), the temperature at the middle could not be so reduced. Again, it has been recognized that as a machine of a given diameter is lengthened, assuming a short core length (say 10 inches for the shortest) the temperatures increased, although the losses per inch of length remained nearly the same.

Nor is a knowledge of the maximum copper temperature, (say at the middle of the machine), the only temperature that is of importance. Some of the large a-c. generators of today are designed for maximum copper temperatures of the order of 150 deg. cent. and then, whether or not the core length be great, the temperature of the copper at the end of the core may be above 105 deg. cent., which temperature may reduce the life of the fibrous insulation which is used on the end windings starting near the end of the core.

Inasmuch as designing and operating engineers are interested in the linear expansion of the straight part of the armature coil due to temperature changes, and are consequently interested in the average temperature of the length of the coil located in the armature slots they may find one of the derived equations (**33a**) to be of value. Again equation (**33**) gives a means of calculating the average temperature of the entire winding, that is, the temperature as measured by the change in resistance.

The maximum copper temperature has usually been taken as the iron temperature plus the drop through the insulating wall, the influence of the temperature of the copper upon the I^2R loss being assumed, and possibly the calculation is then repeated to allow for the new value of temperature. In this paper the condition for infinite length gives an equation (**13**) which brings in the temperature coefficient. The longitudinal flow has been solved by a number of engineers on the basis of constant losses; and Symonds and Walker have taken account of the temperature coefficient.[1]

As is subsequently shown in this paper, none of the above equations is complete, and a general determination of the internal temperature cannot be obtained with any reasonable degree of accuracy (except the maximum and minimum temperatures in long machines) parenthesis unless the simultaneous transverse and longitudinal flows be considered. A solution of that problem is offered in this paper, and it is hoped that the equations may be useful to the designer who is frequently confronted with decisions in regard to the temperatures of the embedded copper in the armature. So far as is known, there are no other formulas published today which are solutions of this problem.

The mathematical solutions offered in this paper were derived a little over three years prior to the writing of the paper, but they were not published at an earlier date, because there were no experimental data available to check calculated temperatures along the copper. The mathematical solutions and data on the experimental checks are both given in this paper.

Method of Attack

The method of attack employed in this paper consists in solving two independent differential equations for heat flow, one for the embedded part of the coil and the other for the end winding, and then combining these two solutions at the point common to the two, viz., the copper at the end of the core. The method of combining the two solutions consists in equating the heat flowing longitudinally from the embedded part at the end of the core to the heat received by the end windings at the same point; in other words, the slopes of the two curves are equal at that point. In general, the temperature of the copper is at its maximum value at the center of the core, so that point is taken as zero for X; similarly the minimum temperature is usually not far from the extreme end of the end winding, and that point is chosen as zero for the independent variable for that part. (This is discussed further under

Presented at the 9th Midwinter Convention of the A. I. E. E. February 16-18, 1921.

1. The equations derived in this paper reduce to the above. Thus, equation (**14**) gives the temperature drop considering only the transverse flow and neglects the temperature coefficient. Equations (**35**) and (**36**) are the usual longitudinal heat flow equations, neglecting temperature coefficient, and equations (**37**) and (**37a**) are for longitudinal flow taking the temperature coefficient of resistance into account.

"The points of Maximum and Minimum Temperature"). Then, considering the total heat generated by I^2R and eddy currents between the zero of reference (point one) and some other (second) point longitudinally as being equal to the sum of the transverse flow between those points and the longitudinal flow beyond the second point, the fundamental equations are easily written.

All of the equations are based upon the conditions which obtain after the steady state has been reached. Consideration of the additional independent variable, time, changes the ordinary differential equations to partials, and complicates them so much even with constant iron temperature, that a solution in practical form has not been obtained. Although the partial differential equations are linear, and admit of integration without difficulty, the combination of the equation for the ends and slot portion bring about equations which are too complicated to be employed readily.

The Iron Temperature

In writing the equations for transverse flow, it has been assumed that the temperature of the iron adjacent to the outside surface of the coil is known. For most machines, especially those of short core length, it is sufficient to consider this temperature as the average of the temperatures axially, and the first equations are worked out on that assumption. However, it is realized that in some of the longer machines, this assumption may not be admissible and that the iron temperature may perhaps approximate a straight line relation with the length, reaching its maximum value at the center of the core; whereas, in other machines, the axial distribution of iron temperatures may not be far from a parabola, again with the maximum temperature at the center of the core. Equations have been solved in which all three assumptions of distribution of iron temperature have been considered. The general method of solution is the same for all three. Inasmuch as the assumption of constant core temperature is the one which, in all probability, will be used most extensively because of its greater simplicity and sufficient accuracy, the supplementary derived equations are given for that case only.

It is hoped that methods for predicting the iron temperatures with greater accuracy than at present will be forthcoming. Such methods will probably include the rate of generation of heat in the various parts of the iron, the rate of flow of heat from the embedded copper to the iron, the transfer of heat from one part of the iron to another, and finally the dissipation of heat from the iron surface; the constants for which, must of course, be determined experimentally. In the meantime, however, it should not be difficult to secure fairly complete data of the tooth temperatures of machines, having stationary armatures of various proportions, by means of, say, embedded thermocouples placed between laminations. Such thermocouples should be so placed as to give information axially and radially; for with the deep slots employed at present the variation in temperature of the iron radially is not always negligible. If the upper coil in the slot (the one nearer the air gap) has materially higher eddy current loss than the lower, and if in addition the temperature of the tooth adjacent to the upper coil is at somewhat higher temperature than the portion of the tooth adjacent to the lower coil, the upper coil will be at higher temperature as a result of the influence of both effects. In the machine, the tests of which are given in this paper, the lower temperatures of the lower coil are due almost entirely to the lower temperature of that part of the tooth. Fig. 11 gives an idea of the variation of tooth temperature with depth. Undoubtedly, this variation in tooth temperature was largely due to the not inconsiderable difference in induction density at the different depths; (the diameter of the machine was quite small).

In many machines, it will possibly be sufficient to take as the iron temperature that of the core measured in the ordinary way by thermometer; a small correction may be added. This should apply to machines like many of our standard induction motors and low-speed alternators having shallow cores and teeth, in which the temperature gradient radially cannot be very great. In the paper "Some Practical Experience with Embedded Temperature Detectors[2]," data are given on a 12,000-kv-a. alternator, in which the average difference between detector readings near the back of the core and in the core at nearly full load was only about three deg. cent.

In employing the temperature figures for the iron, allowance may be made for the cooling of the outside of the coils in the vent ducts in radially ventilated machines. In this calculation, the following should be allowed for:

1. The increase in temperature of the air above the ingoing air;
2. The difference in temperature between the outside coil surface and the air impinging upon it;
3. The weighted mean of the iron temperature and the outside coil surface.

1. More specifically may be approximately determined by considering the losses absorbed by the air before the air encounters the coil; (remembering that the air rise is about one deg. cent. when 1765 cubic feet per minute absorb one kw.).

2. May be approximated by means of an equation like (38) in this paper.

3. The weighted mean for constant core temperature is equal to:

$$\frac{\text{Width of vent} \times \text{av. temp. of outside of coil} + \text{width of iron pkg.} \times \text{av. temp. of iron}}{\text{Width of vent} + \text{width of package of iron}}$$

In general, a rough approximation is sufficient. The cooling of the outside coil surfaces at the vents tends to introduce irregularities in the copper temperature

2. See paper by F. D. Newbury and C. J. Fechheimer, A. I. E. E., June 1920.

curve, but the high thermal conductivity of the copper undoubtedly practically obliterates them.

Eddy Currents

In most large a-c. machines, and in some d-c. machines the eddy current loss due to the load currents may augment the $I^2 R$ loss materially. This loss is not the same for the two coil sides in a slot, and is lower in the end windings than in the embedded part. The formulas derived by Mr. R. E. Gilman[3] are quite accurate but they necessarily involve the temperature coefficient of resistance of copper. In using the equations derived in this paper, it is first necessary to calculate the eddy current factor, and for this a first approximation of the copper temperature must be employed. The eddy current factor in the equations is considered to be constant, and its values should be calculated with the use of the average temperature of the copper in the slots or ends, as the case may be.

It is of interest and value to note that the length of the core of the machine is not the only factor which affects the difference between the maximum temperature as computed by transverse flow only, and the maximum copper temperature which actually obtains. If the section of copper be large,(that is, so large as to secure a nominally low density) but the eddy current loss in the embedded portion be high, the large cross-section of copper permits of flow of heat at a fairly rapid rate to the ends; consequently, even for long core lengths, the longitudinal heat flow may be quite effective in reducing the copper temperature at the middle of the machine. Thus, in a machine, which was built about ten years ago, the nominal density in the copper at full load is 1200 amperes per sq. in., and the calculated eddy current loss plus $I^2 R$ is a little more than twice the $I^2 R$ loss. Even though the core length of that machine is 58 inches, the longitudinal heat flow lowers the temperature, as calculated by means of equations in this paper, 50 degrees below the temperature calculated by means of the transverse equation (on the basis of no longitudinal heat flow).

Thermal Conductivities

The most unsatisfactory constant which is involved in equations of heat flow in electrical machinery is that of the transverse thermal conductivity of the insulating material. Unlike the electrical conductivity of metals, we are never sure within a large percentage what value to choose. Thus ordinary fish paper has been found to vary in transverse conductivity from 0.0047 to 0.0064 watts per sq. in. per deg. cent. When built up in wrappers, with say the addition of mica, such as used on the straight parts of some coils, the combined conductivity is materially reduced, (due to the introduction of short paths of low conductivity from layer to layer), and the variation in conductivity is greater than that of paper or other material[4]. For the ends, for which varnished cambric is used, with varnish between layers, which varnish reduces the influence of air pockets and contact resistance, the conductivity is higher, and the variation less than for the embedded portion.

Owing to the fact that a slight amount of volatile matter is driven off at the higher temperature, the thermal conductivity may change with time, especially if the machine be operated at temperatures above 100 deg. cent. The driving off of the volatile matter does not change the thermal conductivity of the individual layers of insulating material so much as it changes the structure of the insulation between layers, thereby changing the conductivity from layer to layer. Naturally, the variations are erratic.

Therefore, it is quite possible that the temperatures of the copper of machines may change slightly after having been in service for some time, and this is also one reason why the internal temperatures on the same machine differ when made under identical conditions, but on different days.

Furthermore, for most insulating materials, the conductivity changes with the temperature, increasing slightly with increasing temperature. When built up in wrappers, the value of the temperature coefficient of thermal conductivity is quite indefinite and on some tests, its value has been found to be zero. In the equations, the thermal conductivity has been taken as a constant, partly because of uncertain value of the temperature coefficient but more especially because of a desire to avoid further complications in the equations.

Owing to the great importance of the transverse thermal conductivity of insulating materials, laboratory tests of the value of thermal conductivities are of great value. Such tests should be made upon a large number of coil wrappers imitating as closely as possible the conditions that obtain in the machine, and the temperatures in such tests should be maintained at values approximating those in service, and be thus maintained until constant conditions are reached.

The thermal conductivity of the copper (longitudinally) is so high compared with the longitudinal conductivity of the insulation (of the order of 1000) that the neglect of any heat flow longitudinally through the insulation may well be justified. The conductivity of copper has been taken as 9 watts per sq. in. per in. per deg. cent. in the calculations to be found in this paper, and, as in the case of insulation, the temperature coefficient of heat conductivity has been neglected. Various authorities give somewhat different figures for the conductivity of copper, and the value of 9 chosen may be a little lower than that given by most

3. Eddy Current Losses in Armature Conductors, A. I. E. E., June 1920.

4. Some data on Thermal Conductivity of Insulating Material may be found in articles by T. S. Taylor in the *Electric Journal* for December 1919, and the *Elec. World* for Feb. 14, 1920; also in paper by Symonds and Walker "Heat Paths in Elec. Mach.," I. E. E., 1912.

of them. The Smithsonian tables, for example, give, about 9.6 whereas Symonds and Walker used as low value as 7.6.

Emissivity from End Windings

Next to thermal conductivity of the insulation, the most unsatisfactory constant which is employed in the equations is that of emissivity from the end windings. Every electrical manufacturer has an enormous amount of data on temperatures taken by thermometer on the surfaces of the ends of the coils, but none of such data can be directly applied. The reasons therefor are:

1. Most of the temperatures were taken after shutdown, and some of the heat flowed out from the embedded portion of the coil, and thereby influenced the reading;
2. The temperatures of the copper inside the coils at the particular spot where the thermometers were placed were not known; and if they were known the watts per unit surface would have to be calculated from the drop in temperature through the wall of insulation and from a supposed knowledge of the conductivity of the insulating wall;
3. Most data do not give the spacing between coil ends;
4. There were no records taken of the air velocities upon which the rates of heat dissipation are very largely dependent;
5. There are no records of the angles of incidence of the air.

It is believed to be best to make such emissivity tests on suitable models in a laboratory, using dummy coil ends. A description of one set of such tests is given in a recent number of the *A. S. M. E. Journal.*[5] Those tests are far from complete, as they were made on one coil only; however, data from that set of curves should be helpful until more complete data are available.

In the equations which are given in this paper, the watts per sq. in. per deg. cent. have been taken to be constant, although with variable spacing, with supports for the coil ends at intervals, with variable air velocity, with different angles of incidence of the air, etc., that factor must be quite far from being constant; it is probable, however, that the value chosen (0.045) is sufficiently close approximation to the average value which obtained in the machine. Nevertheless, some of the departures between test and calculations may be in part due to the inaccuracy of the value chosen, and to the variability of that factor. Fortunately, in many machines in which the air velocity is fairly high, or the wall of insulation is rather thick, the variation of the emissivity factor along the coil, and the incorrect choice of its average value, do not have so much influence on the final results as might at first thought be supposed; because the drop through the insulating wall on the ends is usually of considerably greater influence than the drop from the external surface to the cooling air.

The Points of Maximum and Minimum Temperature

One of the terminal conditions for evaluating one of the integration constants for the embedded portion is that at the center of the core, or for $X = O$, the temperature is at its maximum value. This assumption is usually in fairly close keeping with the conditions that actually obtain in the machine. However, with certain constructions it may be advisable to choose some other point for that of maximum temperature. For example, in most large axially ventilated turbo generators, there are fairly large radial vent ducts near the middle of the machine. The cooling air which passes over the coil surfaces near the middle of the machine reduces the temperature there, so that in such cases, it is considered advisable to take the end of the iron adjacent to the first vent duct as the point of maximum temperature; that method has been employed in the calculations to be found in this paper.

The point of minimum temperature that has been chosen in the equations for evaluating one of the integration constants in the end windings, is the extreme end of the winding. Such assumption is quite accurate provided that the temperature curves for the upper and lower coils are identical. As is usually the case, however, the upper coil temperature in the embedded part is higher than that for the lower coil, owing to higher tooth temperature adjacent to the upper coil and the higher eddy current loss in the upper coil. If, then, the rate of cooling the ends of the upper and lower coils be the same, the point of minimum temperature is on the lower coil at a short distance from the coil-end. Thus, in Fig. 9, the test curve for the particular coil located in slot numbers 9 and 21 has been drawn in dot and dash, for the 300-ampere heat run; and it will be noted that the minimum temperature is about 28.5 inches, instead of 32.5 inches, from the center of the core.

If the difference in temperature between the upper and lower coils be considerable, it may be advisable to calculate the temperatures on the assumption that the point of minimum temperature is beyond the extremity; that is, that L_b[6] for the upper coil is greater than L for the lower coil. Otherwise, the calculated curves for the upper and lower coils will not meet at any point, a condition which, of course, must be fulfilled, in the machine. It is further of interest that the moving of the point of minimum temperature from the extremity of the winding to some point on the end of the lower coil, has the effect of reducing the maximum tempera-

5. "The Dissipation of Heat by Various Surfaces" by T. S. Taylor, abstract in A. S. M. E. *Journal* for April, 1920. The complete paper contains useful curves not appearing in the abstract.

6. L_b is the length of winding from the core to the extremity. See list of Symbo s

ture of the upper coil, and of raising the maximum temperature of the lower coil, although such changes are too small to be of consequence. In fact, if the maximum temperature is the only one sought, it is believed that the error introduced by taking the minimum temperature at the end of the winding is quite negligible in machines of usual proportions.

THE TRANSVERSE AREA

The area per unit length through which the heat flows has been taken as the average area of the part of the perimeter from which the heat is dissipated, and the corresponding perimeter of the copper. For the embedded part with two coil-sides per slot, the two sides adjacent to the teeth plus one of the other sides are taken as the area (see Fig. 2). This assumes that there is no heat escapment from the two coil sides adjacent to each other. Such assumption is not strictly correct, for as was shown in the paper on "Embedded Temperature Detectors,[7]" the heat flow to the slot-sides has an appreciable influence upon the reading of the detector placed between coil-sides in the usual way. The magnitude of such heat flow is, however, very small, compared with the total transverse heat flow. Especially when consideration is given to the uncertainty of such important factor as the transverse thermal conductivity of the insulating material, the assumption is well justified.

For the end windings, in the special case for which the solution is given, the outside surface from which the heat is dissipated (for unit length) is taken as the external perimeter of one coil; and the average area through which heat flows is taken as the average of the external perimeter and the copper perimeter. In the particular problem adjacent coils were fairly well separated, so that the cooling air was effective in reaching all sides of the coil. However, such assumption may not be admissible in some machines (as many small induction motors) in which practically no air can pass between adjacent coil ends. The areas which should be chosen for the external surface Q' and that offered for transverse flow Q_b in the ends, must be decided after study by the designing engineer.

The question has been raised as to the inaccuracy of the "average area" equation, instead of the more exact logarithmic expression. The derivations and comparisons are given in the appendix, and it is there shown that with typical high-voltage (say 13,200)dimensions, the difference is less than 1 per cent. With low-voltage insulation, the difference is even less than for high-voltage.

(To be continued)

EXTENSION OF DEWEY DECIMAL CLASSIFICATION APPLIED TO RADIO

A year ago the radio laboratory of the Bureau of Standards, Washington, D. C., prepared a tentative scheme of classification of radio subjects. This has now been revised as an extension of the Dewey Decimal System and is useful in classifying radio references, drawings, books, and reports. The whole subject of radio communication is put in its proper place in the Dewey Classification—621.384—but it is suggested that these figures be abbreviated to the use of the letter *R*, in a purely radio library. An abbreviated classification is provided for the use of small libraries or collections. An alphabetical index enables one to refer readily to the classification number of any subject desired.

The main headings into which the subject of radio is divided are as follows:

R000 Radio Communication
R100 Radio Principles
R200 Radio Measurements and Standardization
R300 Radio Apparatus and Equipment
R400 Radio Communication System
R500 Application of Radio
R600 Radio Stations—Operation and Management
R700 Radio Manufacturing
R800 (Vacant or to be used for non-radio subject matter)
R900 Miscellaneous Radio

It is desired to make this classification as complete, comprehensive, and usable as possible, and the Bureau of Standards will be glad to send a copy of the complete classification to any persons interested, so as to place it in the hands of those having use for it and also with a view to possible future revision.

HYDROELECTRIC POWER DEVELOPMENT IN NEW ZEALAND

In his annual report to Parliament the Minister of Public Works has announced a progressive hydroelectric power development scheme to cover the next few years, writes Consul General Alfred A. Winslow, of Auckland, New Zealand, in *Commerce Reports*. The scheme consists of a complete high-tension transmission system in both the North Island and the South Island, connecting up the different hydroelectric power centers with the many electric power board districts.

* * * * *

The potential power of the proposed hydroelectric developments in the North Island amounts to 341,000 h. p., with equal possibilities in the South Island. It is estimated that the North Island scheme will cost $50,000,000, and that the South Island plan will not fall much behind.

These developments will call for large quantities of electrical machinery and supplies, much of which might be supplied by American manufacturers if they could arrange to assist in financing these extensive schemes. . . . .

The development of these schemes will be closely watched, and later plans and specifications covering the different installations will be forwarded to the U. S. Department of Commerce. Meanwhile, communications addressed to L. Birks, Public Works Department, Wellington, New Zealand, should have early attention.—*Electrical Record.*

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

A. I. E. E. MARCH MEETING, NEW YORK

The 368th meeting of the A. I. E. E. will be held in New York, Friday evening, March 11th in the Engineering Societies Building.

The program will be under the auspices of the Power Stations Committee, and the subject of the meeting will be "Developments in Conversion Apparatus for Edison Systems" by T. F. Barton and T. T. Hambleton both of the General Electric Co. The paper is printed elsewhere in this issue. One main paper will be presented and will be followed by several prepared discussions.

FUTURE A. I. E. E. MEETINGS

APRIL, PITTSBURGH

The 369th meeting of the A. I. E. E. will be held on Saturday. April 16, 1921, in Pittsburgh, Pa. This will be a joint meeting with the Association of Iron and Steel Electrical Engineers and the general subject of the meeting will be "The Power Supply of the Pittsburgh District in Relation to the Steel Mill Industry."

Two papers will be presented on behalf of the A. I. E. E. and two papers on behalf of the A. I. and S. E. E. The A. I. E. E. papers are on the "New Colfax Station of the Dusquesne Light Company—Electrical Features" by D. L. Galusha and the "Mechanical Features" by C. W. E. Clarke. The A. I. & S. E. E. papers are "Problems of Conversion from 60 Cycles to 25 Cycle" by B. G. Lamme, and "Some Results in the Change of 60-Cycle to 25-Cycles Energy" by D. M. Petty.

The program includes a visit to the Colfax plant in the morning followed by luncheon; an afternoon session at which the papers on the Colfax plant will be presented and discussed; informal dinner, and an evening session at which the papers by Messrs. Lamme and Petty will be presented.

MAY, NEW YORK

The 370th meeting of the A. I. E. E. will be held in the Engineering Societies Building, New York, May 20, 1921. This is the Annual Meeting of the Institute, at which the result of the annual elections is announced and the report of the Board of Directors is presented. A technical program to be announced later will follow the business session.

ANNUAL AND PACIFIC COAST CONVENTION, SALT LAKE CITY, JUNE 21-24

Plans for the combined Annual and Pacific Coast Convention are progressing. At the meeting of the Board of Directors held February 16, the Chairman of the Meetings and Papers Committee reported that the committee has tentatively scheduled four technical sessions, under the auspices of the Electrical Machinery, the Industrial and Domestic Power, the Transmission and Distribution Committees, and a miscellaneous session. It is intended that these technical sessions will be held on the four mornings of the convention, leaving the afternoons and evenings open for other events.

Mr. H. T. Plumb of Salt Lake City has been appointed by President Berresford as Chairman of the Convention Committee, the complete personnel of which will be announced in a later issue. Mr. Plum and his associates of the Utah Section have already made considerable progress in planning events for the four afternoons and evenings, including opportunities for several visits to power plants, mines and other places of engineering interest; also several social events which will be of more particular interest to the ladies in attendance.

FUTURE SECTION MEETINGS

Cleveland.—March 14, 1921. Subject: "Electric Propulsion of Ships." Speaker: Mr. W. E. Thau, Westinghouse Electric & Mfg. Co. This will be a joint meeting with the Association of Iron & Steel Electrical Engineers.

Detroit-Ann Arbor.—March 18, 1921. Joint meeting with Detroit Engineering Society, to which all of the A. I. E. E. sections in the Great Lakes District, also the Toledo and Cleveland Sections, are invited. Inspection trips will be made during the day and a get-together dinner will be held at 6:30 preceding the paper of the evening. This will be "The Story of the Induction Motor," by Mr. B. G. Lamme, Chief Engineer of the Westinghouse Elec. & Mfg. Co.

Kansas City.—March 25, 1921. The meeting will be held at the Northeast Power House of the Kansas City Light & Power Company. Mr. H. C. Blackwell, General Manager of the Kansas City Light & Power Company, will give an illustrated talk on the design and operation of the power plant of that company.

San Francisco.—March 25, 1921. Subject: "A Variable Voltage Railway Converter Substation." Speaker: Mr. J. E. Woodbridge, Resident Engineer, Ford, Bacon & Davis. Meeting will be held in the new substation of the United R. R. of San Francisco.

Schenectady.—March 18, 1921. Subject: "European Economic and Industrial Situation." Speaker: Mr. David B. Rushmore.

Vancouver.—March 20, 1921. Subject: "Electrical Energy Rates." Speaker: Mr. E. E. Walker. Joint meeting with B. C. Technical Association.

April 1, 1921. Subject: "High-Voltage Transmission in British Columbia." Speaker: Mr. J. Muirhead.

THE 1921 MIDWINTER CONVENTION

The Ninth Midwinter Convention of the A. I. E. E., held February 16-18, 1921, in the Engineering Societies Building, New York, proved to be one of the most successful Midwinter Conventions of recent years, both in point of attendance and in the general interest manifested in the technical papers and discussions. The registration of members and guests totaled over 1000 names.

Wednesday afternoon was devoted to the registration of members and guests, and to trips to the plants of a number of electrical companies who courteously invited inspection by members and guests attending the Convention.

As indicating the activity of Institute work at this time, it may be mentioned that twelve committee and sub-committee meetings were held on Wednesday and Thursday during the Convention as follows: Meetings and Papers Committee, Publication Committee, Standards Sub-Committee on Insulators, Electrical Safety Conference Sub-Committee on Oil Circuit Breakers, Electrical Machinery Committee, Membership Committee, Mines Committee, Finance Committee, Transmission and Distribution Committee, Protective Devices Sub-Committee on Oil Circuit Breakers and Switches, Library Committee and Standards Sub-Committee on Telegraphy and Telephony.

Wednesday Evening

The first technical session was called to order in the auditorium at 8:15 p.m. on Wednesday by President Berresford, who delivered a brief address concerning the service of the engineering profession, excerpts from which appear elsewhere, after which he turned the conduct of the meeting over to Mr. D. W. Roper, Chairman of the Protective Devices Committee, under whose auspices the technical session was held. The following papers were then presented:

Present Day Practise Limitations of Oil Circuit Breakers. By Subcommittee on Oil Circuit Breakers and Switches of the Protective Devices Committee, H. E. Woodrow, Chairman.

High-Current Tests on High-Tension Switch-Gear, By Philip Torchio.

Moving pictures and oscillograph records of switches at the instant of failure were shown.

The papers were discussed by Selby Haar, Peter Junkersfeld, E. P. Peck, H. E. Trent, N. L. Pollard, E. E. F. Creighton, William A. Moore, and written discussion by N. J. Conrad. The authors made closure on their respective papers.

Thursday Morning

The technical session Thursday morning, which was devoted to a symposium on "Operating Temperatures of Low-Voltage Paper-Insulated Cables," was opened by Mr. W. A. Del Mar, who acted as Chairman during the session, and the following papers were presented:

The Maximum Safe Operating Temperatures of Low-Voltage Paper-Insulated Cables, By W. A. Del Mar.

Permissible Operating Temperature of Impregnated Paper Insulation in Which the Dielectric Stress is Low, by Philip Torchio.

Permissible Operating Temperatures of Impregnated Paper Insulation in Which the Dielectric Stress is Low, by D. W. Roper.

Notes on the Effect of Heat on Impregnated Paper From Cable Insulation, by W. S. Clark.

The Effect of Heat upon Paper Insulation, by H. W. Fisher.

Permissible Operating Temperatures of Impregnated Paper Insulation in Which the Dielectric Stress is Low, by L. L. Elden.

Those who took part in the discussion of the papers were Frank M. Farmer, George B. Shanklin, E. B. Meyer, W. I. Middleton, Comfort A. Adams, H. R. Woodrow, P. H. Chase, R. J. Wiseman, William Maver, Jr., Philip Torchio, D. W. Roper, A. E. Kennelly, F. D. Newbury, C. N. Rakestraw, Harold C. Dean, Dugald C. Jackson and R. W. Atkinson.

Thursday Afternoon

The session on Thursday afternoon was called to order by President Berresford, who turned the meeting over to Mr. Donald McNicol, Chairman of the Committee on Telegraphy and Telephony. Two papers were presented at this session. The first, entitled *Carrier-Current Telephony and Telegraphy*, by E. H. Colpitts and O. B. Blackwell, was presented by Mr. Colpitts. The next paper, *Some Phases of Railroad Telegraph and Telephone Engineering*, by Stanley Rhoads, was then presented by the author. The discussion which followed was participated in by Major General George O. Squier, A. E. Kennelly, E. C. Keenan, C. E. Davis, H. M. Turner, H. W. Drake and John L. Niesse.

Thursday Evening

On Thursday evening a Dinner-Dance was held in the Ballroom of the Hotel Astor, at which considerably over four hundred members and guests were in attendance. This Dinner-Dance has come to be a regular feature of the Midwinter Conventions of the Institute and has always proved a most enjoyable and popular social function.

Friday Morning

The technical session Friday morning was under the auspices of the Instruments and Measurements Committee and was presided over by Mr. F. V. Magalhaes, Chairman of that committee. The papers presented were as follows:

Regulation of Frequency for Measurement Purposes, by B. H. Smith.

Measurement of Relative Eddy Current Losses in Stranded Cables, by J. A. Cook.

An Electromagnetic Device for Rapid Schedule Harmonic Analysis of Complex Waves, by F. S. Dellenbaugh, Jr.

The Limitations of the Stopwatch as a Precision Instrument, By A. L. Ellis.

The papers were discussed by J. R. Craighead, Charles F. Scott, W. H. Pratt, J. B. Whitehead, R. W. Atkinson, F. V. Magalhaes, A. Karapetoff, H. M. Smith, L. N. Potts, with closures by the authors.

Friday Afternoon

The final technical session of the Convention was called to order Friday afternoon by W. I. Slichter, Chairman of the Meetings and Papers Committee. The first paper to be presented was entitled *Short-Circuit Current of Induction Motors and Generators*, by R. E. Doherty and E. T. Williamson. The paper was presented by Mr. Doherty. The next paper, *Hysteresis Effects with Varying Superposed Magnetizing Forces*, by W. Fondiller and W. H. Martin, was presented by Mr. Fondiller, and the final paper on *Longitudinal and Transverse Heat Flow in Slot-Wound Armature Coils*, by Carl J. Fechheimer, was presented by the author.

Those who took part in the discussion were V. Karapetoff, Lawrence E. Widmark, M. I. Pupin, Selby Haar, Charles W. Burrows, B. A. Behrend, R. B. Williamson and Carl Hering. Written discussion was also presented by N. S. Diamant, G. E. Luke and M. A. Savage.

Friday Evening

The Presentation of the Edison Medal to Dr. M. I. Pupin of Columbia University took place in the auditorium, Friday evening at 8:30 p. m. After calling the meeting to order, President Berresford said a few words in explanation of the origin of the Edison Medal and then introduced Colonel J. J. Carty, who made the presentation address. Colonel Carty described at length the work and inventions of Dr. Pupin, especially in connection with telephone industry. He paid a high tribute to the work of the medallist whose inventions have been one of the chief factors in extending the radius and

improving the quality of telephonic communication. The Medal and Diploma of Award were then presented to Dr. Pupin by President Berresford.

Dr. Pupin then gave a most interesting address, entitled "Wave Transmission," during which he described some of his early experiences in Serbia and various incidents of his life and education leading up to his telephonic inventions. In closing, he expressed his most sincere appreciation of the honor conferred upon him by the Institute in presenting him with the Edison Medal, which constituted the highest honor which the Institute could bestow.

EXCERPTS FROM ADDRESS OF PRESIDENT BERRESFORD AT OPENING SESSION

In gathering for this—our Ninth Midwinter Convention—we are fulfilling one of the stated purposes of our association, namely, the holding of meetings for the reading and discussion of professional papers, to the end that the theory and practise of Electrical Engineering and of the Allied Arts and Sciences may be advanced and that there shall be maintained a high professional standing among our members.

Gregariousness—a flocking together—is an oft-noted trait of human nature, but it becomes a dominating instinct where men possess some strong interest in common. If no American Institute of Electrical Engineers had ever been formed, we would form one tonight almost without consideration in order that we might possess facilities for the discussion of the matters which most engage our daily thought.

But whatever might be the specific object for which we associated, at some time in the course of that association we would inevitably find ourselves departing in some measure from it. Essaying some other effort—higher and less self-centered, if the fundamental motive be altruistic—meaner and narrower, if the dominant note be self-interest.

The complicated civilization of the present day exhibits this process of association at its maximum and its effects are difficult to estimate, but, without question, enormous. Each individual instance produces some effect upon the body politic, if for no other reason than that the association simply existed. Slight it may be, and either for good or evil, but inevitable. If it be in the interest of humanity, the rate of progress is increased—if contrary, it is retarded. We begin the exercise of this influence immediately we have formed ourselves into an associated body. It is utterly beyond our power to live to ourselves alone, or solely for our own objects. Whether we will or no, we at once become a factor in what shall be, and exert an influence on when it shall come to be.

If this be true of but a few men—and it is true—what care then must be exercised by an association of the magnitude of the Institute, to the end that all of our doings may redound to the good of our people, our race and the world as a whole.

Having recognized this responsibility, which became ours by the very act of association, may we nor well inquire as to our fitness for meeting it? Have we any peculiar qualification which particularly fits us, and if so, may more be expected of us than of those not so liberally endowed? It seems to me that we have. We are a body of professional men, or men on their way to become professional men. From time immemorial the professional man—teacher, minister, doctor, soldier—has been acepted on a basis of substantial equality by those of high degree and recognized as possessing uncommon qualification by those of less fortunate placing. The engineer (starting from the soldier as the military engineer, and throughout all of the diverse branches of the profession recognized today) has similarly enjoyed this distinction.

The very persistence of this recognition throughout the years indicates that it must possess substantial foundation. Mere educational superiority is not sufficient explanation and sinple self-assertion would not have given permanence.

I conceive it to reside in a single fundamental characteristic—the fact that there comes to each a moment (and in that moment he becomes truly a professional man) when the work itself—the instinct to do or to create—utterly outweighs the element of resultant personal advantage. Having once attained the experience, the mental habit becomes fixed, material concerns assume their true proportion and there results a class of men whose aims and whose ideals become accomplishment for accomplishment's sake, and whose ultimate end—although not always self-recognized—becomes the serving of their fellows.

The world recognizes the effect without seeking the cause. It perceives a man who is aiding its advancement, with subordinated self-interest and without ulterior motive, and so long as he displays these qualities holds him superior. This is the professional man, and this willingness to serve has become the fundamental tradition of his class.

The engineer has well maintained the tradition. He may not have put it into words. He may not have consciously recognized it in himself other than as a duty and as such to be accepted and performed, but his accomplishment makes evident the existence of the underlying ideal.

And there is no insignificant body of him in this country of ours. A reasonable estimate seems to place the number of engineers alone as in the neighborhood of one hundred thousand—one for each four hundred of our working population. If such a body of men—so trained and so animated—speak as a unit after due consideration, they will receive attention. If they act as a unit, they will accomplish.

There will be leaders in the work—men of extended accomplishment and commanding personality—and through them will come that coordination and direction of the work of the individual which makes for the maximum of performance; but without the work of the individual they can do nothing. Through association of the individual we can develop the conclusions upon which to predicate action and again through association we may best assure that action.

As I come into contact with the work that has been done in the Institute by the men who have given and are giving freely of themselves in every capacity to serve it and through it their fellows, I cannot but be impressed with the extent to which this tradition of service has made itself evident in them.

To it must be credited that common bond of which our gathering here tonight is but a visible evidence and only through its continuance may we look forward to an indefinite succession of similar assemblies, and the adequate performance of the duties which devolve upon us.

A. I. E. E. DIRECTORS MEETING FEBRUARY 16, 1921

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Wednesday, February 16, 1921, at 3:00 p. m.

There were present: President A. W. Berresford, Milwaukee; Past President Calvert Townley, New York; Vice-Presidents Charles S. Ruffner, New York, L. T. Robinson, C. S. McDowell, Schenectady, E. H. Martindale, Cleveland; Managers Walter A. Hall, Boston, Wm. A. Del Mar, W. I. Slichter, L. E. Imlay, E. B. Craft, New York, Wilfred Sykes, F. F. Fowle, Chicago, G. Faccioli, Pittsfield, Frank D. Newbury, Pittsburgh; Treasurer George A. Hamilton, Elizabeth, N. J.; Secretary F. L. Hutchinson, New York.

The Board ratified the approval by the Finance Committee of monthly bills amounting to $16,640.59.

Reports were presented of meetings of the Board of Examiners held February 7 and 11, 1921; and the actions taken on applications at those meetings were approved. Upon the recommendation of the Board of Examiners the following action

was taken upon pending applications: 229 Students were ordered enrolled; 277 applicants were elected to the grade of Associate; 9 applicants were elected to the grade of Member; 16 applicants were transferred to the grade of Member; 5 applicants were transferred to the grade of Fellow.

Chairman Slichter of the Meetings and Papers Committee presented a progress report of the March 11th (New York), April 16th (Pittsburgh), and May 20th (Annual Business) meetings, which had already been approved by the Board. Details may be found elsewhere in this issue.

A petition was granted for authority to organize an Institute Section at Omaha, Nebraska.

Authority was granted for the establishment of a Student Branch at Cooper Union, New York City.

Announcement was made of the appointment by the President as required by the constitution, of the Tellers Committee to canvass and report upon the nomination and election ballots in connection with the 1921 election of Institute officers.

President Berresford informed the Board regarding an invitation which had been extended to the Institute by the American Engineering Standards Committee, under date of January 24, to appoint a representative and an alternate on a General Correlating Committee for Mining Standardization, advising that he had appointed Mr. F. L. Stone, of the General Electric Company, Schenectady, as the Institute's representative. Mr. Stone is a member of the Institute's Mines Committee, the Chairman of which, Mr. Graham Bright, has already been appointed to the Correlating Committee by the A. I. M. E. Mr. Berresford stated that an alternate would be appointed later.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

THE INSTITUTION OF ENGINEERS (INDIA)

Communications received recently at A. I. E. E. Headquarters from Mr. Hugh W. Brady, Secretary, The Institution of Engineers (India), Clive Buildings, Calcutta, announce the inaugural meeting of that Institution in Calcutta, February 23-25, 1921, including the annual general meeting, technical sessions, visits to engineering enterprises, social events, and so forth.

Sir Rajendra Nath Moekerjee, K. C. I. E., Hon. Life Member I. Mech. E., has succeeded Sir Thomas Ward as President of the Institution.

JOHN FRITZ GOLD MEDAL

Awarded to Sir Robert Hadfield of London

The John Fritz Medal Board of Award at its annual meeting on January 21, awarded its gold medal and diploma to Sir Robert Hadfield of London for the invention of manganese steel.

Manganese steel was first described in a paper read by Sir Robert Hadfield before the International Engineering Congress in 1893. For uses in which toughness combined with great strength is demanded, manganese steel is invaluable. It is also non-magnetic. Its applications, therefore, have been manifold and various; it is used in enormous quantities the world around.

During the war, thousands of soldiers' lives were saved by manganese steel, for it was found to be the most effective material for helmets and body armor. Nine million Hadfield manganese steel helmets were used by the English American and Belgian armies, and this type was replacing the French type in the French armies when the war ended. These manganese steel helmets were vastly superior to the German helmet, which were made of nickel-chromium steel and were twelve ounces heavier.

Robert A. Hadfield was born in 1859. He has made many inventions in connections with the steel industry and has been a prolific technical writer, receiving many honors for his achievements. Besides manganese steel, he invented a magnetic steel of high permeability, that is a steel which is especially suitable for use in generators and motors. It was long thought that the purer the iron the better would be its qualities for use in generators and motors, but Hadfield showed that a steel containing 2½ to 4 per cent of silicon after a double heat treatment, was far superior to the purest obtainable iron. He is a member of many scientific societies in England and other countries, among them the American Institute of Mining and Metallurgical Engineers and the American Institute of Electrical Engineers. He has been an energetic promoter of the scientific societies of Great Britain and has done much to increase their usefulness. Although so distant from New York, he is one of the greatest users by mail of Engineering Societies Library.

The John Fritz Medal was established in 1902 to honor John Fritz, the great iron master of Bethlehem, Pennsylvania, to whom the first medal was awarded in that year on his eightieth birthday. In 1905, the medal was awarded to Lord Kelvin for his work in cable telegraphy and other scientific attainments. On the list of recipients of the medal are many distinguished namse.

In 1906 and succeeding years, it has been bestowed upon:

George Westinghouse for the invention of the air brake;

Alexander Graham Bell for the telephone;

Thomas A. Edison for numerous electrical and other inventions;

Charles T. Porter for advancing the knowledge of steam engineering;

Alfred Noble for notable achievements as a Civil Engineer;

Sir William H. White for notable achievements in Naval Architecture;

Robert W. Hunt for contributions to the development of the Bessemer process of making steel;

Professor John E. Sweet for advancement in machine design and development of the high-speed steam engine;

Dr. James Douglas for achievements in Mining Metallurgy, Education and Industrial Welfare;

Dr. Elihu Thomson for electrical inventions and scientific research;

Dr. Henry M. Howe for investigations in metallography of iron and steel;

J. Waldo Smith, the Chief Engineer of the Catskill Aqueduct;

General George W. Goethals, the builder of the Panama Canal;

Orville Wright for the development of the airplane.

The medal is awarded annually for notable scientific or industrial achievement by a board of sixteen prominent men representing the National societies of Civil, Mining, Metallurgical, Mechanical and Electrical engineers.

SCANDINAVIAN FELLOWSHIPS TO BE AWARDED

The American-Scandinavian Foundation, 25 West 45th Street, New York, will award twenty fellowships for graduate study in the Scandinavian countries, ten being in Sweden, five in Denmark and five in Norway, covering a wide variety of subjects. Application papers will be mailed on request to James Creese, Jr. at the office of the Foundation.

Candidates must have been born in the United States or in some of its possessions, must be capable of original research and must submit a definite plan of study. It is desirable that they be college graduates and speak at least one language besides English. The stipend is generally $1000, but in a few cases $1200. The period of study includes one academic year.

Application papers must be filed at the office of the Foundation before March 15th and successful candidates will be notified about April 15th.

AMERICAN ENGINEERING COUNCIL

MEETING AT SYRACUSE, N. Y. FEBRUARY 14, 1921

A business meeting of American Engineering Council was held at the hotel Onondaga, Syracuse, N. Y., on the morning and afternoon of February 14, 1921, with Herbert Hoover presiding. The most important action at the meeting was the election of L. W. Wallace as Secretary of The Federated American Engineering Societies. Mr. Wallace has already been serving as Treasurer of the Federation and as Vice-Chairman of its Committee on Industrial Waste. Upon his election as secretary the office of treasurer became vacant, and W. W. Varney of Baltimore was elected temporary treasurer.

Mr. Wallace was graduated in mechanical engineering from the Agricultural and Mechanical College of Texas in 1903. He afterward served a railroad apprenticeship and became instructor at Purdue University, then assistant professor of car and locomotive design, and finally, in 1913, head of the department of railway and industrial management, which position he held until 1917. He received the degree of M. E. from Purdue in 1912. Upon leaving the university he became assistant general manager of the Diamond Chain and Manufacturing Co., Indianapolis, Ind. At the close of the war, when the Red Cross Institute was established at Baltimore for the purpose of giving vocational training to blind soldiers, Mr. Wallace left Indianapolis to become director of the Institute and conducted the work until last January, when he was elected treasurer of The Federated American Engineering Societies. In the conduct of his many activities he had displayed breadth of vision and has been actuated by altruistic motives, characteristics which, combined with an executive experience and a deep interest in the principles of management, admirably adapt him for the work he is to undertake. In various addresses on the subject of industrial management before The American Society of Mechanical Engineers and elsewhere he has shown insight into the fundamentals underlying industrial unrest and a sympathetic appreciation of the rights as well as the responsibilities of employee and employer. This latter will be the most favorable asset to Mr. Wallace in conducting the important investigation dealing with the elimination on waste in industry which is to be undertaken by the Federation.

Various business matters relating to the work of the Federated American Engineering Societies were transacted at the meeting. The Council strongly endorsed the model bill on registration of engineers previously prepared by Engineering Council. It also approved legislation proposed in connection with the Nolan Patent Bill providing for a reciprocal arrangement with foreign countries to remove discrimination against patents in foreign countries held by American inventors. Announcement was made of the membership of the Federation's Committee on Elimination of Waste in Industry, appointed in accordance with the suggestion of Herbert Hoover that the subject be taken up as one of the major activities of the Federation. The personnel of the Committee is as follows: J. Parke Channing, Chairman; L. W. Wallace, Vice Chairman; Robert B. Wolf, Chas. E. Knoeppel, Robert Linton, J. H. Williams, Fred. J. Miller, L. P. Alford, Ira N. Hollis, George D. Babcock, Morris L. Cooke, E. E. Hunt, Harrington Emerson, H. R. V. Scheel, and F. G. Coburn. It was voted to recommend to President-Elect Harding that an engineer be appointed on the Interstate Commerce Commission. Before adjournment the next place of meeting of the Council was announced to be Philadelphia.

EXTRACTS FROM ADDRESS OF HERBERT HOOVER PRESIDENT AMERICAN ENGINEERING COUNCIL

The Federation of Engineering Societies has been brought about solely that we might secure for public service the collective thought and influence of 100,000 to 200,000 of our professional engineers. This great body of men in administrative and technical service penetrates every industrial avenue and thus possesses a unique understanding of many of our intricate economic problems and an influence in their solution not equalled by any other part of the community. Wanting nothing from the public either individually or as a group, it is indeed in a position of disinterested service. This Federation has initiated services to the public in many directions.

I propose to deal with only one measure of this service today. Your Council has organized a preliminary survey of some of the weaknesses in our production system. This survey will attempt to visualize the nation as a single industrial organism and to examine its efficiency towards its only real objective,—the maximum production. In a general way this inquiry will bear upon the whole question of deficiency in production—industrial waste in a broad sense.

The waste in our production is measured by the unemployment, the lost time due to labor conflict, the losses in labor turnover, the failure to secure maximum production of the individual due either to misfit or lack of interest. Beyond this again is a wide area of waste in the poor coordination of great industries, the failures in transportation, coal and power supplies which reecho daily to interrupt the steady operation of industry. There are again such other wastes due to lack of standardization, to speculation, to mismanagement, to inefficient national equipment and a hundred other causes. There is a certain proof of deficient production by comparisons of our intense results in 1918, when, with 20 per cent of our man-power withdrawn into the army, we yet produced 20 per cent more commodities than we are doing today. We are probably not producing more than 60 or 70 per cent of our capacity; that is, if we could synchronize all national effort to maximum production, we could produce 30 or 40 per cent more commodities and service. Our national machine is today doing worse than usual, as witness the 3,000,000 idle men walking our streets. One part of the human measure of this shortage in production is the lack of necessities or comforts to them and their families, and their anxieties as to the future.

No one will ever suppose that it is ever possible to bring national productivity up to the full 100, but the whole basis of national progress, of an increased standard of living, of better human relations, indeed of the advancement of civilization, depends upon the continuous improvement in productivity. While we currently assume that great advances in living standards are brought about by new and basic invention, yet in fact even a greater field of increasing standards lies in the steady elimination of these wastes. The primary duty of organized society is to enlarge the lives and increase the standards of living of all the people—not of any special class whatever. We are therefore proposing to make a preliminary examination of the volume of waste in certain industries, the proportions that lie in each field of fault. And no engineering report is worth the paper it is written upon without constructive suggestions in remedy.

The largest area of waste lies in the large periods of slack

Delivered before meeting of American Engineering Council at Syracuse, New York, February 14, 1921.

production and unemployment, due to the ebb and flow of economic tides between booms and slumps. The ideal would be steadily increasing production—an ideal of no likelihood of exact realization because of inability to ever gage the advance in growth consumption or the approach of saturation. On the other hand, there are certain possibilities of stabilization worth consideration. For instance, we can classify labor into that engaged in production and service from this equipment. Our studies of industries as a whole show that we usually expand our equipment just at the periods of maximum demand for their products instead of doing our plant expansion during periods of slack consumption. We thus make double demands on labor and we doubly increase unemployment in periods of reduced consumption. That is indeed one of the factors in our great unemployment today. Everyone knows that for our normal productivity, our transportation facilities are today inadequate. We know that we are insufficiently housed, insufficiently equipped in our public roads and our public utilities; that we need an entire revision of our power supply, that we need expansion of our waterways, and yet armies of idle men are walking the streets. The reasons why this occurs are not far to seek, in that it is at times of high productivity that capital is most easily obtained. It is then that the necessity of increased equipment most impresses men's minds and it is the high hopes of these periods that lead them into the adventure of expansion. Nor is it possible to expect that all industry could be so stabilized as to do its capital construction in periods of depression in commodity demand. Nevertheless, there are some industries that could, by cooperation of the government and cooperation amongst themselves, be led in this direction. More particularly does this apply to railways, telephones, telegraphs, power supplies and other public utilities, and to the expenditure upon our state, municipal and national public works.

Another variety of intermittent employment, and thus great waste, lies in certain industries now operating upon an unnecessarily wide seasonal fluctuation, as for instance the bituminous coal industry. This is today one of our worst functioning industries. These mines operate seasonally and erratically. They proceed from gluts to famines, from profiteering to bankruptcy. As already determined by our engineering bodies, the men who mine our coal find work only 70 per cent of their time. In other words, there are 30 per cent more equipment, 30 per cent more men, attached to this industry than are necessary if it were stabilized to continuous operation. The mining engineers have already pointed out the directions in which remedy lies, through storage, through railway rate differentials and other remedies. Through constructive action, an army of men could be released from this industry of necessity to convert some luxury into a necessity of tomorrow.

The second largest area of waste in productivity is the eternal amount of labor friction, strikes and lockouts. The varied social and economic forces involved in this problem need no repetition here. Fundamentally this is not alone a struggle for division of the results of production between capital and labor, but there is also a loss greater from strikes and lockouts in the element of purely human friction and loss outside the area of dispute on wages and hours. The growth of industry into large units has destroyed the old mutuality of interest between employee and employer. Our repetitive processes have tended to destroy the creative instinct and interest in employees; at times their efforts sink to low levels indeed. We will yet have to reorganize the whole employment relationship to find its solution. There is great promise in this field during the past two years, and the progress in this matter is one of the subjects under our inquiry.

Yet another variety of loss lies in the unnecessarily faulty distribution of our labor supply due to seasonal and to shifting demands. An adequate national employment service is indeed the first need to reduction of these wastes.

Probably the next largest fraction of waste in productivity lies in a too high degree of individualism in certain basic products and tools. In other words, a standardization of certain national utensils makes for economy in distribution, in operation and in repairs. The necessity of maximum production during the war opened a great vista of possibilities in this direction. Such standardization as car couplings, or wheels, and cars generally, represent real progress in this direction. These possibilities lie in a hundred directions. It is certain that there are a great many articles of every-day use in which the manufacturer would indeed be glad to undertake some cooperation in standardization, from which the saving in national effort would be interpreted not into millions but into billions of dollars. This does not mean that we stamp the individuality out of manufacture or invention or decoration; it means basic sizes to common and every-day things.

Another type of waste lies in our failure to advance our industrial equipment. The Superpower Survey will demonstrate the saving of 25,000,000 to 50,000,000 tons of coal annually by the electrification of our eastern power supply. The St. Lawrence Waterway Commission will demonstrate the saving of five to ten cents a bushel to the farmers of fifteen states by unlocking the lakes to ocean-going vessels. Nor will this added efficiency to our national transport injure our present systems of canals and waterways, for we have ever found that the prosperity of an industry blesses them all.

Nor do we believe it is necessary to effect these things by the government. The spirit of cooperation that has been growing in our country during the last thirty years has already solved many things; it has standardized some things and is ripe for initiative toward cooperation of a wide-spread character. The leadership of our Federal government in bringing together the forces is needed. No greater field of service exists than the stimulation of such cooperation. The first step is sane analysis of weakness and sober proposal of remedy. If the facts can be established to an intelligent people such as ours, action is certain even if it be slow. Our engineers are in unique position for this service, and it is your obligation to carry it forward.

CURRENT ENGINEERING TOPICS

BOARD OF SURVEYS AND MAPS

Under the authority of special Executive Order, the Federal Power Commission, Army Air Service and Naval Aviation have been added to the membership of the Board of Surveys and Maps and instructed to name their representatives. At a postponed meeting of the Board held on Feb. 9 the same officers were reelected for the ensuing year, namely, O. C. Merrill, Chairman, Wm. Bowie, Vice-Chairman, and C. H. Birdseye, Secretary. It was decided that committees would be partially reorganized so as to better distribute the work. The regular public meeting will be held on March 8 to which representatives from all outside organizations are invited.

RECLASSIFICATION AND COMPENSATION OF ENGINEERS IN GOVERNMENT SERVICE

The chairman of the House Committee on Reform in the Civil Service announced on February 1st that no hearings would be held on the Reclassification Bill, which means that this bill will die when Congress adjourns. The report of this committee and the bill which was drawn as a result of this report would have affected practically every engineering position in the Government and would have meant a raise in salary under the new classification.

WORK OF FEDERAL POWER COMMISSION

As a result of the hearings January 24-26, it was decided that no applications involving the prospective use of water from Niagara Falls under an amended treaty with Great Britain

will be considered by the Commission. The Commission will, however, give consideration to possibilities under additional diversion in considering proposals for the use of existing water. It was also made plain that the International Joint Commission will have to consider the proposed developments in the gorge. The principal considerations in addition to the power will be the retention of scenic features and protection against ice jams in this gorge development.

The House Committee on Interstate Commerce has reported two bills, H. R. 14469 and 15126, the first of which removes jurisdiction of the Commission over National Parks and the latter provides increased personnel and salaries for the employees of the Commission. It is contemplated that a special rule can be obtained in the House so that these bills can come up for immediate action. The Senate adopted an amendment to the Sundry Civil Bill on Feb. 5 decreasing the general appropriation of \$100,000 to \$80,000, providing a salary of only \$5,000 for the Executive Secretary and reducing salaries of present employees beyond what they now are receiving which means that the work of the Commission will be seriously curtailed for the coming year. This amendment can probably be blocked by the House conferees, especially if H. R. 15126, explained above, is passed by the House.

As a result of hearings before the Commission on Februay 10 and 11, a revision of Regulations 11 to 17 has been made embodying many of the suggestions made to the Commission. These regulations are as follows:

11. General considerations affecting approval
12. Project work
13. Lands reserved or classified as power sites
14. Annual charges
15. Benefits from headwater improvements
16. Depreciation reserve
17. Expropriation and allocation of earnings

It is expected that the revised copies will be ready for distribution soon. The Commission is also to be asked to give final authority to authorize formal issue of licenses to 12 applicants whose projects have been advertised. The Commission has issued its report recommending a start on this development. The complete report has been printed as a Senate document. Over 175 applications for licenses or permits have been received to date.

AMERICAN ENGINEERING STANDARDS COMMITTEE

CEMENT SPECIFICATIONS MADE UNIFORM

Complete agreement has been reached on Specifications and Tests for Portland Cement. so there is now one specification covering both commercial and governmental use. Only minor changes were necessary in order to eliminate slight but long-standing discrepancies which had existed between the industrial specifications and those of the Government.

The revised specifications, which were agreed upon by Committee C-1 of the American Society for Testing Materials and the government Departmental Committee on Cement, have received the approval of the American Engineering Standards Committee.

Copies may be obtained from the American Engineering Standards Committee, 29 West 39th Street, New York, or from the American Society for Testing Materials. The price is 25 cents.

"NATIONAL ELECTRICAL CODE" SUBMITTED FOR APPROVAL

The National Fire Protection Association has submitted its "Regulations of the National Board of Fire Underwriters for Electric Wiring and Apparatus," edition of 1920, frequently referred to as the "National Electric Code," to the American Engineering Standards Committee for approval as an "American Standard."

This Code is submitted in accordance with the special provision in the procedure of the Committee, under which important codes in existence prior to 1920 may be approved without going through the regular process followed in new work.

The Committee would be very glad to learn from those interested, of the extent to which they make use of this Code and to receive any other information regarding the Code in meeting the needs of the industry.

Copies of the Code may be obtained from the National Board of Fire Underwriters, 76 William Street, New York, or from the American Engineering Standards Committee.

SPECIFICATIONS SUBMITTED FOR APPROVAL

The American Society for Testing Materials has submitted the following specifications to the American Engineering Standards Committee for approval as "Tentative American Standards":

Standard Test for Toughness of Rock.

Standard Method for Distillation of Bituminous Materials Suitable for Road Treatment.

Standard Method for Sampling Coal.

The specifications are submitted in accordance with the special provision in the procedure of the Committee, under which important standards in existence prior to 1920 may be approved without going through the regular process followed in new work.

The Committee would be very glad to learn from those interested of the extent to which they make use of these specifications, and to receive any other information regarding the specifications in meeting the needs of the industry.

These specifications may be found in the 1918 volume of A. S. T. M. Standards. Copies may also be obtained from the American Engineering Standards Committee.

BUREAU OF MINES SPECIFICATIONS BEFORE A. E. S. C.

The Bureau of Mines has brought three of its publications to the attention of the American Engineering Standards Committee for consideration as "Tentative American Standards." They are:

Permissible Portable Electric Mine Lamps (Schedule 6A)

Specification for Storage Battery Locomotives (Schedule 15)

Suggested Safety Rules for Installing and Using Electric Equipment in Bituminous Coal Mines (Technical Paper 138)

They are submitted for consideration in accordance with the special provision in the procedure of the Committee, under which important specifications in existence prior to 1920 may be approved without going through the regular process followed in new work.

The Committee would be very glad to learn from those interested of the extent to which they make use of these specifications and rules, and to receive any other information regarding them in meeting the needs of the industry.

Copies of these publications may be obtained from the Bureau of Mines, Washington, D. C., or from the American Engineering Standards Committee.

STANDARDIZATION OF INSULATED WIRES AND CABLES

A conference on the standardization of insulated wires and cables was held in New York, February 2d. The conference which was called by the American Engineering Standards Committee at the instance of the American Railway Engineering Association, was attended by representatives of fourteen national organizations.

After a thorough discussion of the many considerations involved, it was unanimously decided that, "The unification of specifications for wires and cables for other than telephone and telegraph use should be undertaken under one general plan, covering substantially all the more important uses." It was agreed that work on the following should be included:

Conductor, quality, stranding, sizes.
Rubber insulation.
Varnished cloth insulation.
Impregnated paper insulation.
Magnet wire (including enamel, cotton and silk insulation).
Fibrous coverings (including asbestos).
Sheaths.
Armor.
Standard make-ups.

Nearly a dozen organizations now have important publications on the subject, and it was agreed that the proposed work should be a unification of the specifications and standards already in existence, rather than an attempt to formulate entirely new standards, except in fields not already covered.

It was the consensus of opinion that, in order to promote export trade, it would be desirable to have all the American wire and cable standards assembled in a single book. This form of publication, while giving due credit to the participating organizations, would appear to foreign wire and cable purchasers as a complete book of American Standards, rather than as the standards of societies comparatively unkown abroad. This has been done in a very thorough way by the Germans and to a considerable extent by the British, thus placing Americans at a decided disadvantage in foreign trade. It was agreed that if such a book were prepared and given proper publicity in foreign countries, it would remove one of the greatest difficulties under which American manufacturers are now laboring in developing export trade.

The proposed work will be carried out under the auspices and rules of procedure of the American Engineering Standards Committee.

RECENT FOREIGN ENGINEERING STANDARDS

Copies of the following engineering standards, issued in 1920 by foreign national standardizing bodies, are on file with the American Engineering Standards Committee.

British Engineering Standards Association
- No. 1 Rolled Steel Section for Structural Purposes, Lists of
- No. 12 Portland Cement, Specifications for
- No. 94 Watertight Glands for Electric Cables, Specification for
- No. 97 Watertight Fittings for Incandescent Electric Lamps, Specifications for
- No. 100 Body Spaces and Frame Ends for Chassis for Private Automobiles, Dimensions for
- No. 106 Electrically Heated Cooking Range, Specification for
- No. 122 Milling Cutters and Reamers, Standards for
- No. 131 Notched Bar Test Pieces, Forms of

Canadian Engineering Standards Association
- No. 1 Steel Railway Bridges, Standard Specification for

Association Belge de Standardisation (Belgium)
- No. 1 Construction of Metal Framework, Rules for
- No. 2 Construction of Metal Tanks, Rules for
- No. 3 Construction of Coverings and Partitions of Corrugated Galvanized Sheet-iron, Rules for
- No. 4 Shafts and Transmission Pulleys, Standardization of
- No. 5 Construction of Metal Bridges, Rules for

Hoofdcommissie voor de Normalisatie in Nederland (Holland)
- N 19 Compression Couplings
- N 20 Flange Couplings
- N 29 Loose Collars for General Construction
- N 30 Loose Collars for Millgearing

Normenausschuss der Deutschen Industrie (Germany)
- DIN 187 Angle Arm for fixed Bearings for Transmission Shafting
- DIN 475 Widths of Spanner Jaws

Commission de Normalisation du VSM (Switzerland)
- VSM 10300 to VSM 10307 Technical Drawings—Oblique Script; Size of Letters; Graphic Presentation of Screw; Cross-Sections
- VSM 12050 Screw-Whitworth Threads: General Data
- VSM 33900 to VSM 33914 "Sulzer" Attachment for Milling Cutters

Sveriges Maskinindustriförening (Sweden)
- SMS 1 Size for Standard Sheet
- SMS 2 Metric Screw Thread System
- SMS 3 Whitworth Screw Thread System
- SMS 5 Hexagonal Nuts-Type B6M-BSW Screw Thread System
- SMS 7 Finished Hexagonal Screws-Type B6S-BSW Screw Thread System
- SMS 8 Series of Standard Diameters

Photostatic copies of these standards can be furnished at a nominal cost, or the copies on file may be consulted at the offices of the American Engineering Standards Committee.

INSTITUTE OF RADIO ENGINEERS

OFFICERS AND BOARD OF DIRECTORS FOR YEAR 1921

The annual election of officers recently held by the Institute of Radio Engineers resulted in the election of E. F. W. Alexanderson, president; Fulton Cutting, vice-president; A. N. Goldsmith, secretary, and W. F. Hubley, treasurer. The Board of Direction of the Institute is made up of the officers and the following managers: E. H. Armstrong, W. H. G. Bullard, E. H. Colpitts, L. Espenscheid, J. V. L. Hogan, L. R. Krumm, R. H. Marriott, Donald McNicol and George O. Squier.

NATIONAL RESEARCH COUNCIL

AN INFORMATIONAL SERVICE CONCERNED WITH METALS AND ALLOYS

An Alloys Research Association is being formed with an Alloys Informational Service as the first step. This is to be cooperative on the part of those interested in metals and their alloys. An Advisory Committee, composed of 17 prominent technical men, was formed sometime ago and this committee has evolved a plan, in conference with the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers, whereby a service of a different scope from any now existing can be carried on for the benefit of the alloy men. It has been felt that it is time to broaden the sources of knowledge and to have a cooperative service that will critically and analytically digest the great mass of data that has been accumulated, but is now largely inaccessible. Technical men have not the time to spend in searching even all of the current literature. It is now planned to create a special scientific staff composed of a director and a corps of assistants who will give all their time to rendering a service of two distinct types—(1)Current Informational Service—supplying information as to new results; (2) Reference Service—supplying as fully and promptly as practicable all existing information relating to any phase of a subject. The Board of Managers, appointed by three of the divisions of the National Research Council, is constituted of Mr. Alfred D. Flinn, Secretary of Engineering Foundation, Dr. R. B. Moore of the Bureau of Mines, and Mr. W. M. Corse, Secretary of the Institute of Metals Division of the American Institute of Mining and Metallurgical Engineers.

The Research Extension Division of the National Research Council, Washington, D. C., which is aiding in the organization, will be glad to supply fuller details about this service.

MEETING OF DIVISION OF ENGINEERING

Some benefits to industry resulting from research scientifically conducted were interestingly stated by Dr. Charles L. Reese, Chemical Director, E. I. Du Pont de Nemours & Company,

and Mr. A. J. Wadhams, General Superintendent, International Nickel Company, in addresses before the Division of Engineering of the National Research Council, February 4, at the Engineers Club, New York.

Dr. Reese emphasized the value to industries of organized research in particular. Some research projects are not immediately productive of financially profitable returns, others yield great savings or large profits immediately. If research be properly organized, or conducted on a cooperative basis by one great industry or a group of industries, a winning average, from the accountant's method of keeping score, is much more likely to be made. But organization and cooperation must be so conducted that the individual research worker feels no restraint. Mr. Wadhams told of the hurdles research had to take successfully in order to become established in old industrial plants. Three groups particularly required "converting," the directors, the shop superintendents and the foremen. Success depends largely upon the human qualities of the research personnel and their ability sincerely to recognize the value of the knowledge gained by the practical man in his experience, as well as the knowledge of the laboratory.

Galen H. Clevenger, Consulting Metallurgist, U. S. Smelting and Refining Company, Boston, presided at the meeting of the Division of Engineering, at which there were present twenty-two members and guests, men of high standing as research specialists or executives in leading industries. The Division's work is directed toward stimulation of research in the industries, and bringing about cooperation in the acquisition of new scientific knowledge and its dissemination among engineers and managers of our industries. The Division is supported by the National Research Council and by Engineering Foundation, representing the National Societies of Civil, Mining, Metallurgical, Mechanical and Electrical engineers.

PERSONAL MENTION

RALPH D. MERSHON, consulting electrical and mechanical engineer, announces that his New York office is removed to 143 Liberty Street.

ALLEN E. RANSOM, formerly with the Westinghouse Electric & Mfg. Co., has become Superintendent of the Olympia Light & Power Co., Olympia, Wash.

H. B. BASSETT has been placed in charge of a Chicago office of the Acme Wire Company, opened at Room 1105, Monadnock Block, 53 West Jackson Boulevard, Chicago.

H. R. SEARING, who was located with the Aviation General Supply Depot, Fairfield, Ohio, is now connected with the United Elec. Lt. & Pr. Co., 130 East 15th St., New York.

GEORGE E. SANFORD has been elected president of the American Society of Safety Engineers. Mr. Sanford is with the General Electric Company, West Lynn, Mass.

FREDERICK T. LOHR, who has been with the New York Pyritos Co., Inc., at Gouverneur, N. Y., is now electrical engineer with the Soper-Mitchell Coal Co., Morgantown, West Va.

W. J. DAVIS of the General Electric Co., who has been Pacific Coast engineer at San Francisco, is now located in the Ry. and Traction Engineering Department at Schenectady, N. Y.

FRANK CONRAD of the Westinghouse Electric and Manufacturing Company, has been appointed assistant chief engineer. He has been located with that company for nearly thirty years.

FRED G. SINGER has accepted a position as instructor in Electrical Engineering at the University of Wisconsin. Mr. Singer has been a student engineer with the General Electric Company.

J. B. PRICE has discontinued his connection as New York District Manager of the Refinite Co., Inc., and will be associated from now on with the American Water Softener Co. of Philadephia.

CARROLL H. SHAW is now in the Engineering Distribution & Installation Department of the New York Edison Company. He has been located for the past year with Jackson & Moreland, Engineers, Boston.

WILLIAM A. WEBER, formerly with the Century Electric Co., Philadelphia, has become connected with the Western Electric Co., Chicago, where he will be in the central office engineering division, Hawthorne Plant.

A. H. GRISWOLD, who has been located in San Francisco with the Pacific Telephone & Telegraph Company, has been appointed assistant chief engineer of the International Western Electric Company, Inc., in New York.

HARRY W. OSGOOD of the Bethlehem Shipbuilding Corporation, has been appointed plant engineer of the Fore River works, at Quincy, Mass. He has been with the Bethlehem company since the fall of 1919.

JOSEPH H. LIBBEY, formerly electrical engineer with the Eastern Massachusetts Street Railway Company, has joined the organization of H. M. Haven & Wm. W. Crosby, engineers and architects, with offices at 40 Court Street, Boston.

W. R. WHITNEY, director of the research laboratory, General Electric Company, Schenectady, N. Y., was awarded the Perkin medal on January 14 by the American Section of the Society of Chemical Industry. Dr. Whitney received this honor for his many inventions in chemistry.

WILLIAM EVES, 3rd, whose former address was with the American Vulcanized Fibre Co., Wilmington, Del., is at present working in Germany under the American Food Administration, with the American Friends Service Committee. He expects to return to the U. S. this summer.

CHARLES F. VAN WICKLE has completed his work in designing electrical machinery with the Silk Producers Corporation, Hackensack, N. J., where he has been since April, 1920, and will return to his old work, telegraph engineering. His present address is 573 West 191st St., New York City.

H. C. DEFFENBAUGH has resumed his work as engineer and assistant to the secretary with the Empire State Gas and Electric Association. He was away last year on work in connection with a survey of the water-power possibilities of New York State under the direction of Col. William Barclay Parsons.

ALBERT U. BRANDT, formerly superintendent in the Alameda County District, Pacific Gas & Electric Company, has become electrical engineer of the San Francisco division of that company, and will have charge of the operation and maintenance of the electrical properties and steam generating stations in San Francisco.

J. P. JOLLYMAN of the Pacific Gas & Electric Company, has been promoted to the position of chief of the division of hydroelectric and transmission engineering, in charge of all the engineering work relating to hydroelectric stations, substations

and communication and transmission lines. Mr. Jollyman is chairman of the San Francisco Section of the Institute.

G. M. Cameron is located with the firm of Mayer, Valentine & Cameron, consulting engineers, at 621 Bangor Building, Cleveland. This firm has been in business for about a year and is becoming established, having made plans and specifications for and superintended the installation of such systems as heating, sanitation, illuminating, power, etc. in a number of buildings during the year.

Herbert Laws Webb, formerly connected with telephone work in America, has resumed practise as a consulting telephone expert in London, and took a prominent part in the fierce controversy over telephone rates and methods which has raged in England since the beginning of the year. Colonel Webb served on the Staff of the Royal Flying Corps and of the Royal Air Force during the war, and retired with the rank of Lieutenant-Colonel in 1919. He has traveled extensively in Europe, investigating the telephone business in all the principal countries, and was responsible for starting the first city telephone system in Turkey.

OBITUARY

Donald Bowman of the Commonwealth Edison Company, died January 18, 1921, after an illness of several months. Born September 18, 1881, at Converse, Ind., Mr. Bowman attended school at Marion, Ind., and later took the Electrical Engineering course at the Massachusetts Institute of Technology, from which he was graduated in 1908. He entered the service of the Commonwealth Edison Company during the summer vacation of 1907, and returned there upon his graduation from M. I. T., remaining until last October, when his health caused him to be temporarily relieved from duty. Mr. Bowman was a Member of the Institute, also of the W. S. of E., the Electric Club and the Edison Club.

George La Rue Thompson of the General Electric Company, died on January 3, 1921. Mr. Thompson was born in Corning, N. Y., June 21, 1864, and spent his younger days at Fonda and Elmira, N. Y. In 1882 he started with the New York and Pennsylvania Telephone and Telegraph Co., as manager of exchanges in several counties. He left this company in 1886 to accept a position with the Thomson-Houston Electric Company in Boston, now the General Electric Company. He remained with the General Electric Company ever since, being connected with the Atlanta, Ga., office for awhile, and since 1906 with the Philadelphia office, where he was located at the time of his death as special agent for the company. Mr. Thompson joined the Institute in 1905.

UNITED ENGINEERING SOCIETY

EXTRACTS FROM THE PRESIDENT'S REPORT FOR THE YEAR 1920

Notwithstanding the continued high cost of services and supplies, during the year 1920, the Society has fully administered its property and functions; but at the close, the accounts show that in order to pay for several permanent improvements, make changes in investments for the greater security of several funds, and meet the necessities of the Library, it was necessary to borrow from the uninvested portion of the Depreciation and Renewal Fund.

Although a number of important changes in the occupation of offices by Associate Societies had of necessity to be made, the entire building was fully occupied throughout the year, and a number of applications for space had to be refused.

The building has been most carefully maintained and some deferred maintenance carried out, so that its present condition is generally better than at any time during the last few years.

Recommendations made by the Independence Bureau, employed by the Board, for improving the fire safety of the structure and its occupants have for the most part been effected, and a further report just received states that both structural and housekeeping conditions are excellent.

The membership of the four Founder Societies at the end of the year was 44,655, and of the Associated Societies 22,609, so that a total of 67,264 engineers have headquarters in our building. Other technical societies holding meetings in the building have a large aggregate membership in addition.

On Sunday, April 25, an impressive memorial service for Andrew Carnegie was held in the auditorium under the joint auspices of the Authors Club, New York Public Library, Oratorio Society, Saint Andrews Society and United Engineering Society, at which the orators were Hon. Elihu Root and Hon. John H. Finley.

A Committee on Memorials and Entrance Hall has been studying the placing of war and other memorials in the Engineering Societies Building, the furnishing of the Entrance Hall to make it more usable and attractive, and the establishment on the ground floor of a general information bureau to serve the various societies and their visiting members.

There has also been a revision of the rates charged for the use of the Auditorium and Assembly Rooms, which had not previously borne an adequate share of the general overhead expense; the new rates are still materially lower than those charged for other halls in the vicinity.

Engineering Societies Library

The Engineering Societies Library has continued its steady progress in size and service under the direction of Harrison W. Craver. The Library contains 150,000 books, pamphlets and maps, and is valued at $311,000. Good progress has been made in the recataloging and re-arranging of the books; for this work special appropriations have been continued by the Founder Societies, and during the year $13,422.50 were expended for the purpose.

The income and expenses of the Library during 1920 were as follows:

Debit balance (temporarily advanced by U. E. S.) at end of 1919	$2,602.36
Contributions by four Founder Societies $4000 each	16,000.00
Library Endowment income	5,027.63
Transfer from Library Service Bureau surplus in November	2,000.00
Income from Douglas Fund of A. I. M. E.	5,497.60
Total	$25,922.87
The expenses were	29,114.79
Difference (deficit)	3,181.92
Library Service Bureau	
Actual cash receipts	$22,797.15
Actual cash disbursements for the Service	22,086.88
Surplus applicable to the general overhead of the Bureau	710.27

The business transacted by the Library Service Bureau has increased from $2,410.80 in 1915, to $8,814.93 in 1918, and $22,797.15 in 1920. Efforts are now being exerted to make this valuable service better known throughout the profession. The service rendered by this department of the Library has, during the past year, extended its usefulness to clients in all but four of the states and territories, as well as in 26 foreign countries.

Engineering Council

Engineering Council continued its activities on substantially the same lines as in 1919, retaining and operating its offices in both New York and Washington.

In April, the American Railway Engineering Association

became the sixth member of Council on invitation from United Engineering Society.

An Organizing Conference held on June 3 and 4 in Washington, attended by delegates of many technical societies, led to the establishment of the Federated American Engineering Societies, acting through the American Engineering Council, which held its first meeting in November. The creation of this larger Council with ampler resources, of which three of the Founder Societies became charter members, indicated clearly that it would be unnecessary to continue Engineering Council. At the request, therefore, of Engineering Council and with the consent of the Founder and other societies interested, United Engineering Society by amendment of its by-laws, terminated Engineering Council on December 31, 1920, when the Washington office was taken over by the American Engineering Council, which will establish its headquarters in that city.

Council's financial condition may be summarized as follows:

Resources available for 1920	$31,157.03
Expenditures for 1920	24,842.84
Cash balance December 31, 1920	6,314.19
Other good assets	2,962.84
Total assets	9,277.03
Estimated expenses yet to be met	150.00
Probable balance	$9,127.03

This balance when finally determined will be applicable to the reduction of any obligations which the Board of Trustees may consider to be outstanding.

Engineering Foundation

Engineering Foundation continued its close relations with National Research Council and its contributions to the support of the Division of Engineering. Plans for increasing the endowment were developed by its Chairman, Mr. Charles F. Rand, during the year and a number of persons have been approached and indicate interest. Mr. Ambrose Swasey, in October generously added $200,000 to his previous large gifts, making the total endowment fund $502,834.80. No other gifts have been received, although one friend has offered to give $50,000 if nine others would give equal amounts. The annual income is now at the rate of $25,000. The accumulated unexpended balance on December 31, 1920 was $16,091.76. Important research projects have been assisted, both directly and cooperatively with the Research Council. The field of possible usefulness has been much increased by the most recent addition to the funds.

Further details of the activities of Engineering Societies Library, Engineering Foundation and Engineering Council are given in their several annual reports.

The affairs of United Engineering Society are in a satisfactory condition.

Very respectfully,
J. Vipond Davies
President.

EXTRACTS FROM REPORT OF TREASURER FOR CALENDAR YEAR 1920

Finances

The *Real Estate Account* now includes the following items:

Land	$540,000.00
Building	1,360,183.15
Equipment	33,171.16
Founder Societies Preliminary Expenses	24,000.00
	$1,957,354.31

The *Gross Operating Expenses* for the year 1920 were $77,486.38, as compared with $67,648.14 for the year 1919, an increase of $9,838.24.

The funds available for the *Library Board*, and spent under its direction during the year, amounted to $37,394.88. In addition U. E. S. advanced $5,142.41.

The funds available for *Engineering Council*, and spent under its direction during the year, amounted to $31,157.03, of which $6,314.19 remain unexpended.

The *General Reserve Fund* of $10,000 created by the Board of Trustees at a meeting held November 18, 1914 to be available to take care of unforeseen fluctuations of income and outlay, has been preserved intact, there arising no calls on this fund during the year 1920.

The *Depreciation and Renewal Fund* at the beginning of the year 1920 amounted to $100,199.00. During the year this fund was increased by the sum of $4,016.16 for interest earned by the investments for this fund, and was decreased by $818.75, due to difference in changing investments, making the total December 31, 1920, $103,396.41.

In accordance with the authorization of the Board of Trustees $5,000.00 corporate stock of the City of New York, Water Supply Bonds, due 1962 were sold on Feb. 9 at $4,600.00 and $5,000.00 corporate stock of the City of New York, Registered Bonds, due 1960, on March 8 at $4,587.50 and reinvestment made in $10,500.00 U. S. Second Liberty Loan, due 1942, bought at $9,469.00.

The following summary shows the amounts of the funds held by U. E. S. as of Dec. 31, 1920.

Depreciation and Renewal Fund December 31, 1919	$100,199.00
Interest on invested funds during the year 1920	4,016.16
	$104,215.16
Loss on sale of securities 1920	818.75
Total	$103,396.41
General Reserve Fund	10,000.00
Engineering Foundation Fund	502,834.80
Library Endowment Fund	93,351.25
Total	$709,582.46

Treasurer's Receipts and Payments, Year of 1920

Receipts

Cash on hand January 1, 1920		$12,537.18

Respectfully submitted,

JOSEPH STRUTHERS,

Treasurer

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

EXTRACTS FROM THE ANNUAL REPORT OF THE LIBRARY BOARD

In accordance with the provisions of By-Law 90 of the United Engineering Society, the Library Board submits the report of the Engineering Societies Library for the year 1920, this being the eighth annual report.

Service

Service to members of the Founder Societies and to other engineers shows an increase in quantity over preceding years, and also, we believe, an increased efficiency. The number of readers was 23,788, an increase of 1746 over 1919, when the attendance far exceeded any previous record. The average daily attendance was 78. The attendance after six o'clock in the evening was 4871, or 20 per cent of the total.

The number of inquiries received by telephone also increased. Statistics were not kept of this use, but it is estimated, on the basis of counts made for brief periods, that 3500 calls were answered during the year. Approximately 4500 letters of inquiry for information or copies of articles were also received and answered.

Summarizing all these methods by which the Library was used, it is seen that at least 32,000 inquiries were cared for, one-fourth of which were from engineers who could not use the Library in person. Many of these do not have ready access to reference collections, and would have great difficulty if some central bureau did not exist to supply the data that they need.

The Service Bureau has cared for all inquiries requiring special investigation and requests for translations. It has made 512 searches. In the course of these searches bibliographies were usually prepared, the number during the year being 360. The total number of bibliographies compiled by the Bureau is now 3428. Although many are on such minor subjects as to be of little general interest, the collection is a valuable reference tool.

The Bureau made 113 translations, containing 352,970 words. This is a decided increase over the 71 translations made in 1919.

During 1920 there were 2669 orders for photographs, for which 35,904 prints were made. The corresponding figures for 1919 were 2319 orders and 23,951 prints.

This mail service, by search, translation and copy, has this year reached every state and territory except four, and twenty-

eight foreign countries as well. The amount of translation was 55 per cent greater than in 1919 and the number of photographs was 50 per cent larger.

Contents

On January 1, 1920, the Library contained, ready for readers:

Volumes	115,934
Pamphlets	32,818
Maps and plans	118
Searches	3,221
Total	152,091

During the year there were added to the collection:

	Gift	*Binding*	*Purchase*	*Total*
Volumes	1081	711	545	2337
Pamphlets	1174	130		1304
Maps and plans	243		1	244
Searches				207
Total	2498	841	546	4092

The available material on December 31, after deducting books and pamphlets withdrawn for various reasons, was:

Volumes	116,551
Pamphlets	32,979
Maps and plans	362
Searches	3,428
Total	153,320

The figures given for maps and plans include only those added in the past two years, the older ones having been included as "volumes" in the general accessions.

With the exception of periodicals added by binding, the majority of the volumes added were gifts, or books sent by their publishers for review.

The most important task before your Board is that of classifying the combined collections by a uniform system and preparing a new catalog on this basis. This work was definitely commenced during 1919, as shown by our last report, and has been prosecuted as vigorously as possible during 1920.

The plan followed has proved entirely satisfactory in practise and is already showing results in increased convenience to readers, greater certainty of reference, and decreased desk attendants, although the work is still incomplete.

The work of the Catalog Department to October, 1920, was summarized in the JOURNAL for December, 1920.

FINANCIAL STATEMENT—1920

Library Maintenance

REVENUE

Appropriation for 1920	$26,000.00	
Advanced by United Engineering Society, 1919	2,502.36	
	$23,397.64	
Cash transferred from Service Bureau surplus November, 1920	2,000.00	
Total revenue		$25,397.64

EXPENDITURES

Salaries	$19,439.28	
Books and Binding	6,510.80	
Supplies and Miscellaneous Expenses	2,869.06	
Equipment	295.65	
Total expenditures		$29,114.79
Excess of expenditures over appropriation		$3,717.15

Service Bureau

REVENUE

Cash received for work done during year	$19,050.43	
Outstanding bills	3,184.07	
Total gross revenue as charged on books		$22,234.50

EXPENDITURES

Salaries	$17,040.46	
Supplies	5,046.42	
Total expenditures		$22,086.88
Balance forward 1 January, 1921		$147.62

CASH STATEMENT

Cash received	$21,374.00	
Balance forward from 1919	666.03	
Total receipts		$22,040.03
On account due depositors		131.27
Net cash receipts		$21,908.76

Recataloging

REVENUE

Founder Societies contributions	$10,000.00	
Balance forward from 1919	1,472.01	
Total receipts		$11,472.01

EXPENDITURES

Salaries		13,422.50
Advanced by United Engineering Society		$1,950.49

BOOK NOTICES (JAN. 1-31, 1921)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

ADVANCED SHOP DRAWING.

By Vincent C. George. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. (Engineering education series.) 9 + 147 pp., diagrams, illus., 9 x 6 in., cloth, $1.60.

This textbook is intended for the student who has had some preliminary training in mechanical drawing and who wishes a practical knowledge of drafting as applied to various lines of engineering. Emphasis is placed on such subjects as working drawings, pictorial representation, patent office, electrical and structural drawing, piping layouts and sheet metal work.

AEROPLANE STRUCTURAL DESIGN; a Book for Designers, Draftsmen and Students.

By T. H. Jones and J. D. Frier. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1920. 267 pp., plates, tables, charts, diagrams, 8 x 6 in., cloth. $7.50.

Although several valuable treatises exist dealing with the problems of sustentation, stability and aerodynamics generally, the authors feel a need for a book treating the structural strength of the aeroplane, in which the loading of it and the methods of estimating its strength under load are discussed definitely and practically. The present volume treats in detail of the wings, fuselage, tail plane and elevators, landing gear and rear skid, control surfaces, flying controls and details, and is equipped with numerous tables of data needed by the designer. Complicated mathematical discussions are avoided.

AUTOMOTIVE IGNITION SYSTEMS.

By Earl I. Consoliver and Grover I. Mitchell. First edition. N. Y. and Lond., McGraw-Hill Book Company, Inc., 1920. (Engineering education series.) 10 + 269 pp., illus., diagrams, 9 x 6 in., cloth, $2.50.

This is a systematic course of study of the ignition systems used on automobiles, tractors and airplanes, for those who have to install, adjust and repair these systems in the factory and repair shop.

THE CENTENARY VOLUME OF CHARLES GRIFFIN AND COMPANY, LTD., 1820—1920.

Lond., Charles Griffin and Co., Ltd., 1920. 290 pp., ports., plates, facims., 9 x 6 in., cloth.

This volume is issued to commemorate the hundredth anniversary of the entrance of this well-known firm into the field of technical book publishing. It includes an introduction by Lord Moulton, a history of the firm, and chapters on the progress of scientific literature in various fields during the last hundred years, as marked by its publications. Among the contributors are T. Hudson Beare, Sir W. S. Abell, William Gowland and Henry Louis.

CHEMISTRY AND CIVILIZATION.

By Allerton S. Cushman. Boston, Richard G. Badger. 151 pp., ports., 8 x 6 in., cloth. $2.50.

The author of this work has attempted a brief, readable account of what chemistry has done, is doing, and hopes to do

for mankind, in which the relation of the present and the future to the past will be clearly indicated. Attention is especially given to the industrial applications of discoveries.

Coal in Great Britain.

By Walcot Gibson. Lond., Edward Arnold, 1920. 8 + 311 pp., plates, maps, illus., 9 x 6 in., cloth. $7.50. (Gift of Longmans, Green and Company.)

The present work is intended to supply mining engineers, mine owners and students with a concise account of the more important facts relating to the geology of coal generally, and to the coal fields of Great Britain in particular. The earlier chapters are reproduced, with additions, from the author's "Geology of Coal and Coal-Mining," now out of print. The rest of the book, dealing with the coal-fields, is based on thirty years' personal experience and on various publications.

Concrete Work.

By William Kendrick Hatt and Walter C. Voss. Vol. 1. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 451 pp., illus., diagrams, tables, 8 x 6 in., cloth. $4.00.

This is the first part of a two-volume manual intended to extend the scope of work now possible to the concrete worker of unguided experience by bringing him to an intelligent understanding of the scientific principles underlying his art, and by introducing him to the wider opportunities that exist for him in modern construction. The method used to present the subject is based upon the experience acquired by the Committee on Education and Special Training of the War Department, in training 130,000 soldiers in the various trades connected with military operations. The present volume of the manual contains the development of principles and information of methods of construction and standards, necessary for the construction of the definite building.

Contracts in Engineering.

By James Irwin Tucker. Second edition, seventh thousand. N. Y. and Lond., McGraw-Hill Book Co., 1920. 331 pp., 9 x 6 in., cloth. $4.00.

This book is intended as a practical course showing the contractual basis of engineering work and of business at large, and as a textbook for engineering students with no opportunity for extended study of legal principles. It aims to present those facts and rules that seem likely to be of most value to an engineer in his professional and business career and to give him substantial information upon many legal matters.

Dielectric Phenomena in High-Voltage Engineering.

By F. W. Peek, Jr. Second edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 281 pp., plates, charts, tables, 9 x 6 in., cloth. $3.50.

It is the object of the author to give in this book the properties of gaseous, liquid and solid insulations and the methods of utilizing these properties to the best advantage in the problems of high-voltage engineering. A brief discussion of the dielectric circuit is included.

This edition has been carefully corrected and supplemented by the data that have resulted from investigations since its predecessor appeared.

Drang und Zwang; Eine Höhere Festigkeitslehre Für Ingenieure.

Von Aug. Föppl und Ludwig Föppl. München und Berlin, R. Oldenbourg, 1920. 2 vols. 10 x 7 in., paper. 72 M.

Contents: Die allgemeinen Grundlagen. Die Sätze über die Formänderungsarbeit. Die Biegungsfestigkeit der Platten. Die Scheiben. Die Schalen. Die Drehfestigkeit der Stäbe. Die Umdrehungskörper. Die Härte. Die Eigenspannungen. Die Knick und Ausweichgefahr.

The authors of these volumes discuss some of the more abstruse problems of stress and strain. The work is intended especially for engineers who are fitted, by practical experience, to follow a difficult investigation and apply its results. A knowledge of the elementary theory of the mechanics of materials is expected of the reader.

Eminent Chemists of our Time.

By Benjamin Harrow. N. Y., D. Van Nostrand Co., 1920. 16 + 248 pp., ports., plates, 8 x 6 in., cloth. $2.50.

Contents: Perkin and coal-tar dyes. Mendeléeff and the periodic law. Ramsay and the gases of the atmosphere. Richards and atomic weights. Van't Hoff and physical chemistry. Arrhenius and the theory of electrolytic dissociation. Moissan and the electric furnace. Madame Curie and radium. Victor Meyer and the rise of organic chemistry. Remsen and the rise of chemistry in America. Fischer and the chemistry of foods.

In selecting the subjects of these biographical sketches, the author has attempted to include those whose achievements have intimately affected chemical progress during the past generation or so, and thus to write a history of the chemistry of our times, centered around some of its leading figures. The book emphasizes the personal side. It is nontechnical in character, and intended for laymen as well as scientists. Brief bibliographies are included.

Exporter's Gazetteer of Foreign Markets, 1920-21.

Compiled and edited by Lloyd R. Morris. N. Y., The American Exporter. 23 + 766 pp., maps, tables, 9 x 6 in., cloth. $10.00.

This gazetteer is planned to present concisely facts about markets which have heretofore been obtainable only in scattered primary sources. The information includes the area and population of each country, the population of its principal towns, its commerce, production and industry, telegraphs, telephones and railroads, money, weights and measures, commercial language, principal shipping routes, customs tariff, consular regulations and representation, and similar matters. Maps of the principal countries are included. Foreign currencies and measurements have been converted into American equivalents.

Factory Organization and Administration.

By Hugo Diemer. Third edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 15 + 398 pp., illus. 9 x 6 in., cloth. $4.00.

This book is for officers of manufacturing corporations, works managers, superintendents, accountants, and those in charge of such activities as purchasing, stores, costs and production. The present edition has been revised to conform with the evolution of practise and standards, particularly in relation to organization, personnel problems and the functional control of production. An extensive bibliography is included.

Freileitungsbau, Ortsnetzbau.

By F. Kapper, Zweite auflage. München und Berlin, R. Oldenbourg, 1920. 8 + 365 pp., illus., diagrams, charts, tables, 9 x 6 in., paper. 40 M.

This work on the construction of aerial electric lines is a practical book, fully equipped to answer the questions of the engineer in charge of erection. Theory is reduced to small dimensions, but the information on actual methods is an ample presentation of current German practise, in minute detail. Both transmission and distribution systems are included.

The Gasoline Automobile; its Design and Construction. Vol. 1. The Gasoline Motor.

By P. M. Heldt. Sixth edition. Nyack, N. Y., P. M. Heldt, 1920. 6 + 633 pp., illus., diagrams, charts, 9 x 6 in., cloth. $6.00.

Continued development of the internal combustion engine has made necessary a further revision of this volume. The chapters on the cylinder and the crankcase and oiling system have been rewritten, and that on the piston, piston rings and piston pin revised to accord with modern practise. New material on other subjects has been added in an appendix and new plates added.

Geology of Petroleum.

By William Harvey Emmons. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 14 + 610 pp., illus., maps, 9 x 6 in., cloth.

The author has tried to present, as briefly as is practicable, a perspective of the data on the geology of petroleum, suitable for students familiar with the operation of geologic processes and the principles of stratigraphy. The book discusses the surface indications of petroleum, openings in rocks, the association of petroleum and salt water, reservoir rocks and covering strata, properties and origin of petroleum and natural gas, maps and logs, accumulation of petroleum, structural features of oil and gas reservoirs, deformation of petroliferous strata, metamorphism of petroleum, gas pressure and oil recovery, petroliferous provinces and petroleogenic epochs. Brief sketches of the important oil fields of the world are included, and numerous references given to the literature on them.

HEAT ENGINES; A TEXT-BOOK FOR ENGINEERING STUDENTS.

By David Allen Low. N. Y. and Lond., Longmans, Green and Co., 1920. 7 + 592 pp., illus., diagrams, charts, tables, 9 x 6 in., cloth. $6.50.

The author has attempted to compress into one volume of moderate dimensions sufficient material for a two-years' course in the subject, in which its theoretical and practical sides would be combined. Numerous exercises for the student are included, most of which are original.

A HISTORY OF THE CONCEPTIONS OF LIMITS AND FLUXIONS IN GREAT BRITAIN FROM NEWTON TO WOODHOUSE.

By Florian Cajori. Chic. and Lond., The Open Court Publishing Co., 1919. 8 + 299 pp., ports., 8 x 5 in., cloth. $2.00.

In this small volume, Dr. Cajori reviews the history of an important event in the history of mathematics, the conception of fluxions advanced by Newton, the controversies with Berkeley and others, and the development that the theory underwent in Great Britain during the eighteenth century.

IRRIGATION; ITS PRINCIPLES AND PRACTISE AS A BRANCH OF ENGINEERING.

By Sir Hanbury Brown. Third edition, revised. Lond Constable & Co., Ltd., N. Y., D. Van Nostrand Co., 1920. 15 + 305 pp., plates, illus., 9 x 6 in., cloth. $6.00.

The primary object of this treatise is to collect the guiding principles on which irrigation engineering is based and to furnish illustrations of their application in existing canal systems. The present edition is little changed from the preceding one, except by the addition of an appendix containing information upon changes that have taken place in the works used as illustrations.

The illustrative works are taken from Indian and Egyptian practise and are based upon the author's personal acquaintance with methods in these countries.

THE MAKING OF HERBERT HOOVER.

By Rose Wilder Lane. N. Y., The Century Co., 1920. 6 + 356 pp., port., 8 x 5 in., cloth, $2.50.

Upon the foundation of documents, letters and diaries, and information supplied by Charles K. Field, a friend and college classmate of Mr. Hoover, Mrs. Lane has prepared an informal readable account of his life. The book is unusual in method, but achieves success as an interpretation of the man.

MARGARINE.

By William Clayton. Lond. and N. Y., Longmans, Green & Co., 1920. (Monographs on industrial chemistry.) 187 pp., plates, illus., 9 x 6 in. cloth. $4.75.

This monograph is the first in any language, the author states, to give an account of the modern processes of manufacture of margarine. The chemistry of its constituents is discussed, and the methods of their analysis, as well as of the finished product, are described in detail. Chapters are devoted to butter and renovated butter, and lard compound. A chapter on nutritional chemistry deals with recent investigations on vitamines. References to the principal patents and a very full bibliography are included.

PETROLEUM REGISTER; AN ANNUAL DIRECTORY AND STATISTICAL RECORD OF THE PETROLEUM INDUSTRY IN THE UNITED STATES, CANADA AND MEXICO, 1921.

N. Y., Oil Trade Journal, Inc., 640 pp., 12 x 9 in., cloth. $10.00.

This new edition of the register has been revised and corrected up to the last months of 1920, so that it represents the latest available information. Like its predecessors it attempts to serve as a complete catalog of the industry by including both those engaged in the industry and those who manufacture and sell the materials needed by the oil trade.

The book lists the refiners, marketers and jobbers, producers, pipe lines, natural gas gasoline manufacturers and oil associations in the United States, and the more important firms in Canada and Mexico. Statistics of production, consumption and distribution are included, as are maps of the important oil producing states.

PHYSIOGRAPHY.

By Rollin D. Salisbury. Third edition, revised. N. Y., Henry Holt and Co., 1919. (American science series—advanced course.) 15 + 676 pp., plates, illus., 9 x 6 in., cloth. $4.00.

The new edition of Professor Salisbury's well-known textbook has not been changed in plan, but has been thoroughly revised throughout and rewritten in considerable part. The text is intended for students of early college grade and represents the course given in the University of Chicago. The book is distinguished by its wealth of illustration and its lists of references to other literature.

PLANTATION RUBBER AND THE TESTING OF RUBBER.

By G. Stafford Whitby. N. Y. and Lond., Longmans, Green and Co., 1920. (Monographs on industrial chemistry.) 16 + 559 pp., plates, diagrams, 9 x 6 in., cloth. $9.50.

The circumstance that the supply of raw rubber is now chiefly derived from plantations, where its preparation can be controlled technically, renders possible the development of cooperation between the producer and the manufacturer, and gives importance to the present account of the preparation of plantation rubber and of present knowledge of exact methods of testing and evaluating raw rubber. The book includes an account of investigations made by physicists into the physical properties of rubber and an extensive bibliography on the subjects covered by the volume.

PROPERTIES OF STEAM AND THERMODYNAMIC THEORY OF TURBINES.

By H. L. Callender. N. Y., Longmans, Green & Co., Lond., Edward Arnold, 1920. 531 pp., diagrams, tables, 9 x 6 in., cloth. $14.00.

This work gives a connected account of the conclusions resulting from the author's extended experimental and theoretical investigations of the problems depending primarily on the properties of steam. It is therefore intended to supplement treatises written from an engineering standpoint, by presenting the thermodynamical aspect of the problem.

The book explains the origin of the author's equations for steam, shows how well his theory has fitted with subsequent work, and how his equations and tables may best be applied to more recent developments. A considerable portion of the book deals with the thermodynamical theory of turbines, and here some new methods are introduced which the author believes will be useful to engineers. The book includes his steam tables.

RECENT ADVANCES IN ORGANIC CHEMISTRY.

By Alfred W. Stewart. Fourth edition. Lond and N. Y., Longmans, Green and Co., 1920. 359 pp., 9 x 6 in., cloth. $7.50.

The author of this work discusses the subject from a synthetic point of view, his object being "to illustrate the principles upon which modern chemistry moves—not stands—and to undermine the conservatism which exists in all but strikingly original minds." Science is to him not a mere collection of data, but rather a rapidly changing series of hypotheses by means of which we attempt to group the facts with which we are acquainted.

This edition includes a new chapter on unsolved problems and other chapters have been revised and extended.

RESEARCH AND METHODS OF ANALYSIS OF IRON AND STEEL AT A. R. M. CO.

Second edition. Middletown, O., The American Rolling Mill Co., 1920. 220 pp., illus., 9 x 6 in., cloth. $4.00.

This volume describes the methods for the magnetic, physical and microscopical testing and chemical analysis of steel used in the laboratories of the American Rolling Mill Company.

SCHMIEDE UND SCHMIEDE-TECHNIK.

By C. Oetling. Band 1. München und Berlin, R. Oldenbourg, 1920. 13 + 608 pp., illus., diagrams, 11 x 8 in., paper. 90 M.

This volume is the outgrowth of a work submitted in 1911 to the Verein deutcher Maschinen-Ingenieure in competition for a prize offered for systematic study of the value of new methods and apparatus for forging. The report has been expanded, at the request of the prize committee into an exhaustive examination of forge shop methods. The present volume, the first of two, was printed in 1914, but has only now been published.

It discusses the fuels, heating furnaces, methods of controlling heat, forging hammers and presses, shears, saws, welding, measuring instruments, cranes and conveyors. The second volume will treat of heat-treating, compressed air machinery, and of the effect of the war on labor. The volume is elaborately illustrated.

THE NEW STONE AGE.

By Harrison E. Howe. N. Y., The Century Co., 1921. (The Century Books of Useful Science.) 289 pp., plates, 8 x 5 in., cloth. $3.00.

The "new stone age" is the age of cement and concrete. The author tells in everyday language the story of cement, its history, manufacture and uses, in the hope that his book will lead to a better appreciation and more thorough understanding of it by the non-technical user, and lead him to use it with due regard not only for its excellent characteristics but for its necessary limitations.

TANKS IN THE GREAT WAR, 1914-1918.

By J. F. C. Fuller. N. Y., E. P. Dutton and Company, 1920. 24 + 321 pp., front., maps, plates, 9 x 6 in., cloth. $9.00.

This volume, by a former Chief General Staff Officer of the Tank Corps of the British Army, is a readable account of the genesis of the tank and of the part played by it in the Great War. The work of the French, German and American tank corps is covered also.

TECHNISCHER LITERATURKALENDER.

2. ausgabe, 1920. München-Berlin, R. Oldenbourg. 441 pp., front., 8 x 6 in., cloth. 40 M.

This is a "who's who" of living German writers on technical subjects, compiled by the chief librarian of the German Patent Office. About seven thousand names are included. The information includes date of birth, address, education, occupation, writings and specialty.

This edition contains a thousand names more than that of 1918, and has also an index by specialties and a list of deaths during 1918 and 1919.

THE TECHNICAL EXAMINATION OF CRUDE PETROLEUM, PETROLEUM PRODUCTS AND NATURAL GAS.

By William Allen Hamor and Fred Warde Padgett. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 9 + 591 pp., illus., tables, charts, diagrams, 9 x 6 in., cloth. $6.00.

This book is designed to present the methods in use for the examination and evaluation of natural gas, crude petroleum and oil-shale, and their important products. It includes the procedures for the physical and chemical tests which are recognized as essential, together with tables of the necessary physical and chemical data. Very full bibliographic references are given.

TELEPHONIC TRANSMISSION; THEORETICAL AND APPLIED.

By J. G. Hill. Lond. and N. Y., Longmans, Green and Co., 1920. (Manuals of telegraph and telephone engineering.) 16 + 398 pp., diagrams, 9 x 6 in., cloth. $7.00.

CONTENTS: Mathematical formulas and notes. The infinite line; Direct-current case. The equivalent circuit, Direct-current case. The loading of transmission lines and the design of artificial cables, Direct-current case. The human voice in telephony. The application of alternating currents to transmission lines. Reflection and power in telephone circuits. The constants of telephone circuits. The loading of telephone circuits, a-c. case. Methods of measurement on transmission lines, with examples of tests. The standard cable and its uses. Cost problems in telephonic transmission. Transmission formulas for lines in series, with apparatus in series and in leak. The thermionic valve as a telephonic relay.

The present volume is one of a series of treatises prepared under the editorship of Sir William Slingo, to deal comprehensively with the problems involved in the applications of electricity in telephony and telegraphy. It treats of the theory and practise of telephonic transmission, and reviews the work that has been done in Great Britain, America, France, Germany and Japan, and is the work of a specialist connected with the British Post Office.

A TEXT BOOK OF CHEMICAL ENGINEERING.

By Edward Hart. Easton, Pa., The Chemical Publishing Co., 1920. 12 + 211 pp., illus., diagrams, 9 x 6 in., cloth. (Gift of the author.)

CONTENTS: Materials. Location of works. Boilers. Prime movers. Plumbing. Crushing. Dissolving. Filtration. Tanks. Evaporation. Crystallization. Drying. Distillation. Absorption of gases. Mixing and kneading. Containers.

The contents give an indication of the scope of Dr. Hart's new book, which is based upon his courses in Lafayette College. The treatment of the subject is brief and elementary, but thoroughly practical.

THE THEORY OF MACHINES.

By Robert F. McKay. Second edition. Lond., Edward Arnold, 1920. 8 + 440 pp., diagrams, 9 x 6 in., cloth, $6.75. (Gift of Longmans, Green and Co.)

CONTENTS: Mechanics. Kinematics of machines. Dynamics of machines.

Although many books exist which cover one or two special parts of this subject, the author believes this to be the first attempt at a systematic, comprehensive review of the whole. The volume is intended for students and engineers, many exercises being included for use by the former. This edition is practically identical with the first, only minor additions and alterations having been made.

THERMO-ELECTROMOTIVE FORCE IN ELECTRIC CELLS.

By Henry S. Carhart. N. Y., D. Van Nostrand Company, 1920. 134 pp., charts, 7 x 5 in., cloth. $2.00.

This little volume is a record of the author's researches, begun many years ago with those concerning the analysis of the temperature coefficient of voltaic cells. The chapter on the electromotive force of concentration cells has especial interest, as it shows the application of the Helmholtz equation to such cells, and the relation of the Nernst equation to this formula.

A TREATISE ON REINFORCED CONCRETE.

By W. Noble Twelvetrees. Lond. and N. Y., Sir Isaac Pitman & Sons, Ltd., 1920. 264 pp., plates, 8 x 6 in., cloth. $7.50.

In this volume the author has endeavored to set forth as clearly as possible the general characteristics and distinctive properties of reinforced concrete and its constituents, to discuss in a systematic manner the principles underlying the design of homogeneous members, and to show how these principles may be applied to the evolution of formulas for the design of reinforced concrete members of different classes. It is restricted to fundamental principles and presents a complete series of formulas for the principal classes of members employed in engineering and building construction.

The book is the first to employ the standard notation adopted by the Concrete Institute. This notation is given in full, with an explanatory foreword.

UNTERSUCHUNGEN UBER SCHWACHSTROMSTORUNGEN BEI EINPHASEN-WECHSELSTROMBAHNEN.

Bericht an die Königl. Schwedischen Eisenbahndirektion von der hierfür ernannten Kommission. Ins Deutsche übertragen durch Franz Kuntze. München and Berlin, R. Oldenbourg, 1920. 159 pp., illus., diagrams, charts, 11 x 8 in., paper 38 M.

In discussions of the comparative merits of direct and single-phase current systems for the electrification of trunk-line railways, one of the most common objections to the latter system is the interference with neighboring telephone lines. The present volume is a German translation of the report of a commission appointed in 1915 to study this question for the railway and telephone departments of Sweden and to prepose remedies. The report describes the investigations carried out by the commission. These included an experimental study of interference on the Kiruna-Riksgränsen railway, a series of direct measurements on the nature of interference phenomena, a theoretical investigation of the effects of conductors upon one another, suggestions for mitigating interference and reports on the theory, design, construction and action of negative boosters.

WINNING THE PUBLIC.

By S. M. Kennedy. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1920. 168 pp., port., 9 x 6 in., cloth. $2.50.

This volume includes the substance of various addresses delivered before technical and trade associations during recent years. They discuss the relations of public utilities with those whom they serve and the methods by which public confidence and good will can be secured.

DIE WECHSELSTROMBAHN-MOTOREN.

Von Max Gerstmeyer. Munchen und Berlin, R. Oldenbourg, 1919. 193 pp., illus., diagrams, 9 x 6 in., paper. 13.60 M.

Having in mind the increasing use of the single-phase motor for railway operation in Europe, the author has prepared this brief account of its principles and chief types for the use of electrical engineers who are not specially informed concerning its theory and uses.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Baltimore.—January 21, 1921, Johns Hopkins University. Joint meeting of the Baltimore Sections of the A. S. M. E. and A. I. E. E., and the Engineers Club of Baltimore. Messrs. C. W. E. Clarke and D. L. Galusha gave a lecture on the New Colfax Power Station of the Duquesne Light Company. This is one of the newest and largest steam driven electrical stations in the country and each speaker took up in detail the unusual problems met with in his respective branch of the engineering profession during its construction, illustrating the lecture by lantern slides. Attendance 125.

Boston.—January 11, 1921. Chipman Hall, Tremont Temple. Paper: "Wireless Telegraphy." Speaker: Dr. F. B. Jewett, Chief Engineer, Western Electric Company. The talk was very interesting; the most novel part was a series of animated cartoons made by the Bray Corporation of the electrons in a vacuum tube in actual operation. The electrons were represented as small white circles and the current in wires by white dashes. There were two reels of moving pictures altogether, some of the circuits being quite pretentious and showing the various events in a complete radio-phone transmitter. Attendance 250.

January 18, 1921. Lorimer Hall, Tremont Temple. Subject: "Electrical Features of the Superpower Survey." Speaker: Mr. W. S. Murray. The speaker spoke very well upon the general problem of the superpower development, and the great wastes that are at present occurring in power development which could be eliminated by the superpower plan. Attendance 200.

February 7, 1921. Boston City Club. Joint meeting of Boston Sections of A. S. M. E. and A. I. E. E., and the Boston Society of Civil Engineers. Two papers were presented as follows: "Recent Water Wheel Developments and Settings," by Mr. W. M. White, Allis Chalmers Mfg. Co., and "Design of the Steam Power Station for Hydraulic Relay" by Mr. E. B. Powell, Stone and Webster. The papers were illustrated by lantern slides. Attendance 250.

Chicago.—January 20, 1921. Joint meeting of the Chicago Section of the A. I. E. E., Railway Section of the Western Society of Engineers, and the Electrical Section of the Western Society of Engineers. Colonel Frederick Mears, Alaska Engineering Commission, gave an illustrated lecture on Alaska, which included moving pictures and slides. Colonel Mears had an exceptional story of the wonders of Alaska, its resources, problems and future. Attendance 350.

Cincinnati.—January 13, 1921. Assembly Hall, Union Gas & Electric Company. Subject: "Elevating Engineering Profession." Speaker: Mr. S. D. Heed, General Manager of the Union Gas & Electric Company. The speaker took for example the construction of Hell Gate Bridge in New York, showing many interesting slides and how this construction showed a daring engineering feat. Attendance 20.

February 10, 1921, Assembly Hall Union Gas & Electric Company. Mr. T. W. Jacobs, of the Chas. A. Schieren Company, explained the manufacturing leather belts, illustrated by a four-reel industrial film entitled "Belt Making from the Salted Hide to the Finished Product." Attendance 30.

Detroit-Ann Arbor.—January 28, 1921. Subject: "Electron Tube and Its Adaptation to the Problems of Communication." Speaker: Dr. Williams. The speaker explained, with the aid of slides and demonstrations, the production of electromagnetic waves, their transmission through space, and the receiving apparatus which is tuned to resonance with the incoming wave. The importance of resonance was clearly shown by experiments. In order to translate the oscillations picked up by a receiving station a detector of some kind is necessary. The electron tube is the best detector at the present time and its sensitiveness assures detection of very weak electromagnetic waves. This was clearly explained and demonstrated. Its ability to amplify very small currents makes it particularly useful in the transmission of speech or of telegraph signals over very long distances.

February 11, 1921. Detroit Board of Commerce. Subject: "Transformers." Speaker: Professor Parker, University of Michigan. The speaker discussed the characteristics and connections of transformers, with particular reference to open delta and star connections on three-phase circuits, also the necessary requirements in transformers for three to two-phase connections. Attendance 45.

Fort Wayne.—January 20, 1921. Mr. Walter H. Sunier of the General Electric Company, talked on the Einstein Theory of Relativity in non-mathematical language. Two reels of interesting film were also shown by the Entertainment Committee; the first reel illustrated the operating methods in the lumber industry and the second the manufacture and use of X-ray tubes. Attendance 80.

Ithaca.—January 29, 1921. Franklin Hall, Cornell University. Subject. "Some Problems in 220-kv. Transmission." Speaker: Mr. F. W. Peek, Jr., The speaker told, interestingly, yet with a minimum of technical and mathematical language, of the problems of present high-voltage transmission, and of what could be expected in the future. Attendance 170.

Kansas City.—January 25, 1921. University Club. Election of officers as follows: Chairman, Professor C. G. Shaad; Secretary, Mr. J. W. Wopat. Mr. H. C. Blackwell, General Manager of the Kansas City Power & Light Company, gave a general talk on the activities of the Institute. Attendance 19.

Lynn.— January 5, 1921. Subject: "Individualism vs. Socialism." Speaker: Mr. Charles E. Carpenter, President of the E. F. Houghton Co., Philadelphia. Attendance 150.

January 19, 1921. Subject: "Industrial Reconstruction in France and Belgium." Speaker: Mr. O. F. Allen. Mr. Allen was a Major with the 24th Engineers and was able to give first-hand information of the conditions in France and Belgium. Among the interesting things which he discussed was the Superpower System which the French are putting in and also the reconstruction of the bridges and lines of communication. Attendance 175.

February 2, 1921. Subject: "The Industrial Applications of Electrochemistry." Speaker: Professor Joseph W. Richards, of Lehigh University. Professor Richards has been indentified with the electrochemical developments at Niagara Falls, and described electrolytic and electrothermal processes. He also described some of the present day applications of these processes and showed the rapid growth that has been made in the electrical and chemical industries since the chemists and electrical engineers got together and combined their efforts. Attendance 150.

Milwaukee.—January 19, 1921, Milwaukee Athletic Club. Mr. A. W. Berresford talked to the Section members regarding the activities of the A. I. E. E. and the work of the Federated American Engineering Societies. Attendance 250.

New York.—January 28, 1921. Engineering Societies Building. Joint meeting of the New York Section of the A. I. E. E. and Metropolitan Section of the A. S. M. E. On Friday evening January 28, another extremely successful joint meeting of the New York Section of the A. I. E. E. and the Metropolitan Section of the A. S. M. E. was held in the Auditorium of the

Engineering Societies Building, New York. The attendance was well over 900.

The meeting was opened with a few remarks by W. S. Finlay, Jr., Chairman of the A. S. M. E. Section. He then introduced the presiding officer of the evening, Alfred E. Waller, of the Marine Committee of the A. I. E. E., and Chief Engineer of the Ward Leonard Company. Mr. Waller pointed particularly to the duty and ability of engineers to place the American Merchant Marine on a plane, not only where it would surpass all others in number, but also where the individual units would carry more weight of cargo per ton and log more knots per given consumption of fuel; where the ships would be safer and stauncher and the time consumed by cargo handling would be reduced to a minimum. Following his talk Mr. Waller introduced Admiral W. S. Benson, Chairman of the U. S. Shipping Board.

Admiral Benson emphasized the tremendous development which has taken place in the naval field, in vessels, mechanical appliances and personnel, since his graduation from the Naval Academy in 1877, and particularly the development of the past ten years in connection with the utilization of oil as a fuel. He was severely criticized in 1911 for having the temerity to take the battleship *Utah* from the Brooklyn Navy Yard to the Hudson River, using fuel oil alone. Admiral Benson expressed the opinion that should the engineering talent of the country devote sufficient study to the subject of motive power and auxiliaries aboard our merchant ships, there was no reason why that equipment should not be placed on a plane of efficiency equivalent to that of the Liberty Motor. The real problem is not one of personnel, but of fuel. We must insist on fuel oil; to return to coal would be suicidal. We must reduce cost of fuel and fuel consumption through the development of an internal combustion engine that will furnish power for complete electrification. Admiral Benson then cited the record of the 12,000 ton *Eclipse* steam turbo-generator, electric drive, which at last report had reached Singapore without the loss of a turn of the propeller, and with a remarkable record in reduction of fuel consumption; but he again emphasized his belief that the ultimate development would be the internal combustion engine combined with electric drive.

He then discussed the heavy charges for loading and unloading vessels, at times amounting to \$20,000 to \$25,000; pointing out the absurdity of wasting time and money to that extent when mechanical appliances would undoubtedly reduce such charges tremendously.

Chairman Waller next introduced the authors of the four papers scheduled for the evening: H. L. Hibbard, Commander C. S. McDowell, Eskil Berg and W. E. Thau. The discussion of these papers was participated in by the following: M. W. Day, J. C. Shaw, R. H. Mc Lain, G. A. Pierce, Commander Jones, W. B. Flanders, and C. O. Giroux.

Philadelphia.—January 21, 1921. Manufacturers Club of Philadelphia. Joint meeting of the Engineers Club of Philadelphia and the Philadelphia Sections of the A. S. C.E., A. S. M. E. and A. I. E. E. Opening of the afternoon technical session by Mr. Guilliaem Aertsen, President of the Engineers Club of Philadelphia. The following papers were then presented: "The Modern Hydraulic Turbine" by Mr. Frank H. Rogers, of the William Cramp & Sons Ship & Engine Building Company, Philadelphia; "The Application of a New Method of Water Measurement in the Efficiency Tests of the 37,500-h.p. Turbines of the Niagara Falls Power Company" by Mr. Norman R. Gibson, of the Niagara Falls Power Company, Niagara, Falls, N. Y.; "Speed Regulation of the Hydraulic Turbine" by Mr. Raymond D. Johnson, Consulting Engineer, New York City; "The Present Trend of Hydraulic Turbine Development" by Mr. Lewis F. Moody, of the William Cramp & Sons Ship & Engine Building Company, Philadelphia. Informal dinner at the Bellevue-Stratford Hotel. Opening of the evening session by the President of the Engineers Club and presentation of moving pictures on "Philadelphia's Waterfront from the Air." The following papers were read; "Niagara Falls Power Development and Its Products in Philadelphia" (illustrated) by Mr. John L. Harper, Vice-President and Chief Engineer, the Niagara Falls Power Company, Niagara Falls, N. Y.; "Electrical Features of Hydroelectric Power" (illustrated) by Mr. David B. Rushmore, General Electric Company, Schenectady, N. Y. Attendance 650.

Pittsburgh.—January 21, 1921. Bureau of Mines. Joint meeting of Pittsburgh Sections of A. I. M. E. and A. I. E. E. A technical session was held at 3:30 p. m., the subject being "Power Rate for Coal Mines" by Mr. H. C. Bailey, Consulting Engineer, Columbus, Ohio. At 5:00 p. m. an inspection trip was made through the buildings of the Bureau of Mines and at 6:30 p. m. a dinner was served in the cafeteria of the Bureau of Mines. The subject of the evening session was "Gathering in Coal Mines" by Mr. R. L. Kingsland, of the Consolidated Coal Co., Fairmont, W. Va. Attendance 150.

February 8, 1921, Chamber of Commerce. Subject "Some Elements of the Electron Theory of Matter." Speaker: Professor V. Karapetoff, of Cornell University. The speaker outlined some recent fundamental experiments and discussed the mathematical relationships, by means of which the size of the electron, its charge of velocity, etc., may be computed. Attendance 350.

Pittsfield.—January 20, 1921. Masonic Temple. Subject: "On the Frontiers of the Universe." Speaker: Mr. B. R. Baumgardt, Lecturer of Los Angeles and New York. Attendance 700.

February 4, 1921, Boys Club. Subject: "Making the Desert Bloom." Speaker: Mr. C. J. Blanchard, Chief Statistician, U. S. Reclamation Service, Washington, D. C. Attendance 250.

Providence.—January 17, 1921. Providence Engineering Society Rooms. Joint meeting of the Providence Engineering Society and the Providence Section of the A. I. E. E. Subject: "Survey of the Proposed Superpower Zone." Speaker: Mr. William S. Murray. Attendance 400.

February 9, 1921, Providence Engineering Society Rooms. Subject: "Switching Equipment for the New England Power System." Speaker: Mr. E. W. Dillard, Assistant Electrical Engineer of the Power Construction Company of Worcester, Mass. Attendance 30.

Rochester.—January 28, 1921. Subject: "Electric Ship Propulsion." Lieutenant R. D. DeWolf, of the New York State Naval Militia, Electrical Officer of the U. S. S. *Nevada* during the war. The talk was accompanied by numerous lantern slides showing the development of turbine drive and electric drive in marine propulsion. The economics resulting from the use of electric drive were clearly pointed out. A moving picture entitled "The Queen of the Waves" showing the development of boat propulsion in America from the primitive methods of the Indian to the completion of the U. S. S. *Mexico*, closed the address. Attendance 72.

St. Louis.—January 26, 1921. Engineers Club. Subject: "The Practical Application of Telephone Repeaters." Speaker: Mr. H. P. Charlesworth, Plant Engineer of the A. T. & T. Co. Attendance 139.

Schenectady.—January 21, 1921, Edison Club Hall. Subject: "Technical Drawings as Applied to Visual Education." Speaker Mr. J. Milnor Dorey, of the Bray Pictures Corporation, New York City. The speaker outlined the application of the use of moving pictures made from drawings in the education for the trades as well as the general distribution of knowledge. Attendance 240.

February 4, 1921. Edison Club Hall. Subject: "Control of Heavy Traction Electric Locomotives." Speaker: Mr. Ray Stearns of the Railway Equipment Engineering Department, General Electric Company, The speaker described the many different systems which have been used for electric locomotives. He began with the 600-volt direct-current system, continuing through the different alternating-current systems and finally to a description of high-voltage direct-current. The different

systems were shown by lantern slides, a locomotive and a wiring arrangement being given in each case. This was followed by general description and illustrations of the methods of regenerative control on the Chicago, Milwaukee & St. Paul Locomotives. At the conclusion of Mr. Stearn's lecture, Mr. W. S. H. Hamilton presented a very interesting talk on practical operating problems where long and heavy freight trains are drawn by electric locomotives. He also described the operating results of regenerative braking and retardation. Attendance 180.

Syracuse.— January 14, 1921, Technology Club. Subject: "The Edison Storage Battery." Speaker: Mr. Walter H. Bancroft, Sales Engineer, of the Edison Storage Battery Co. Attendance 57.

Toronto.— January 28, 1921, Chemistry and Mining Building. Toronto University. Subject: "Technical Education in Canada." Speaker: Mr. Lester W. Gill. Attendance 44.

February 4, 1921, Chemistry and Mining Building, Toronto University. Subject: "The Use of Aluminum Conductors for Transmission Lines." Speaker Mr. Theodore Varney. Mr. Varney opened his talk with a brief summary of the conditions attending the collection of energy for moving trains, suggesting that a satisfactory solution of this problem would be obtained by reducing the clearance to a minimum and supplying a rigid overhead conductor of some light aluminum section. The use of aluminum for power transmission dealt with such points as electrolysis, insulation, tower spacing, sag, wind stresses, splices and methods of installation. A number of slides were shown to illustrate these points and some very interesting pieces of construction, including some very long spans of aluminum were brought to the attention of the audience. Attendance 78.

Urbana.—January 14, 1921, E. E. Laboratory, Univ. of Ill. Subject: "The Manufacture of Watt-Hour Meters." Speaker: Mr. C. R. Horrell, of the Sangamo Electric Company, Springfield, Ill. Attendance 45.

Utah.— January 27, 1921, Commercial Club. Joint meeting of Utah Section A. I. E. E. and Utah Society of Engineers. Subject: "Engineering Opportunities in America's Worldwide Activities." Speaker: Mr. Edwin S. Carman of Cleveland. Attendance 250.

Vancouver.— January 7, 1921. Subject: "The Use of Sem-Diesel Oil Engines in Small Power Plants." Speaker: Mr. Frank Sawford. The paper was well illustrated with lantern slides. Attendance 34.

Washington.—January 11, 1921, Cosmos Club Hall. Subject: "Some Things Engineers Should Know Concerning the Rudiments of Corporate Finance." Speaker: Mr. Ralph D. Mershon. Attendance 152.

February 8, 1921, Cosmos Club Hall. Subject: "Superpower and its Relation to Capital." Speaker: Mr. Harold Goodwin, Jr. The talk was illustrated by lantern slides. Attendance 160.

Worcester.— February 2, 1921. Worcester Polytechnic Institute. Subject: "Superpower and Its Relation to Industry." Speaker: Mr. Henry Flood, Jr. Attendance 135.

PAST BRANCH MEETINGS

Alabama Polytechnic Institute.—January 20. 1921. Papers were presented by Messrs. C. E. Reid and J. M. Dickenson on "Late Developments in the Electrical World." Attendance 26.

University of Arkansas.—January 11, 1921. Election of officers as follows: Chairman, Fred Moore; Vice-Chairman. R. Joerdon; Secretary, S. M. Sharp; Treasurer, G. R. Kilborn; followed by an illustrated lecture on a four wheel drive motor truck. Attendance 18.

January 25, 1921. Subjects: "Development of Radio Service in America" by S. M. Sharp; "Tendencies in the Design of the Power Stations" by W. M. Brewer; "Borrow and Develop Policy—Better than one of Deflation" by Max Ware; "Developments in Material Handling Methods" by Rex Kilborn. Attendance 11.

February 1, 1921. Subjects: "Tendencies in the Design of Power Plants" by W. M. Brewer; "Chances for Technical Graduates with the Westinghouse Company" by W. L. Teague. Attendance 13.

Armour Institute of Technology.—December 10, 1920. Subjects: "The Chicago Lake-Front Improvement" by J. J. O'Rourke; "Machine Switching Telephone System" by G. H. Kelley; "The Development of the Synchronous Converter" by T. L. Albee. Attendance 22.

December 15, 1920. Subjects: "The Ardois System of Signalling" by F. V. Walters; "Gas Engines as Prime Movers" by R. J. Grant; "The Present Outlook for the Engineering Graduate" by Leslie Weiss. Attendance 22.

January 6, 1921. Subject: "Radio Communication Within An Infantry Division" by H. R. Wing. Attendance 28.

Bucknell University.—January 21, 1921. Subject: "The Advantages of Electrical Engineering." Speaker: Prof. R. H. Rhodes. This was followed by an illustrated lecture on the F. W. D. Motor Truck. Attendance 24.

California Institute of Technology.—January 13, 1921. Mr. H. S. Steele, President of the United States Electrical Manufacturing Co. of Los Angeles, gave an illustrated talk on transformer design and construction. Attendance 31.

Case School of Applied Science.—January 11, 1921. Mr. A. F. Wilson of the Ohio Bell Telephone Company, gave an illustrated talk on the changing of the Cleveland Telephone System from the manual to the automatic. Attendance 53.

February 8, 1921. Subject: "Human Repair Work." Speaker: Mr. Ray Finger. Attendance 26.

University of Cincinnati.—January 11, 1921. Mr. E. B. Smith, of the General Electric Company, gave an illustrated talk on "Control of D-C. Motors." Attendance 65.

January 18, 1921. Mr. E. B. Smith gave an illustrated talk on "A-C. Motor Control." Attendance 78.

January 25, 1921. Mr. E. B. Smith repeated his talk on "D-C. Control." Attendance 53.

Clemson Agricultural College.—January 20, 1921. Subjects: "History of the Gas Engine" by L. G. Smoak; "Internal Combustion Marine Engines" by L. H. Hiers; "Automobile Engines" by H. J. Jones; "Current Events" by C. A. Stevenson. Attendance 31.

February 1, 1921. Subjects: "Prime Movers" by C. Yongue; "Motors and Generators" by B. C. Cobb; "General Applications" by B. O'Neil. Attendance 34.

Drexel Institute.—January 28, 1921. Subject: "Advantages of Starting Engineering in the Drafting Room." Speaker: Charles E. Bonine. Attendance 26.

University of Iowa.—January 17, 1921. Subjects: "Insulators" by G. Miller; "Farm Lighting" by C. Longerbeam. Attendance 31.

January 24, 1921. Subjects: "The Automatic Substation" by R. D. Mott; "The Keokuk Power Plant" by R. C. Mathews; "Practical Test and Remedies for Electrical Wiring Troubles" by R. V. Morse. Attendance 33.

Iowa State College.—January 25, 1921. Subject: "Novel Applications of Electricity." Speaker: Mr. A. F. Riggs, General Electric Company, Chicago, Ill. Attendance 106.

February 3, 1921. The following moving pictures were shown: "The Benefactor" and "Cuban Sugar." Attendance 91.

University of Kansas.—January 12, 1921. Subjects: "Village Street Lighting" by Seymore Cronk '21; "Tendencies of White Way Lighting" by Dana McCall '21. Attendance 28.

Lehigh University.—January 20, 1921. Paper: "Industrial Engineering." Author: Mr. H. P. Liversidge, Philadelphia Electric Co. Attendance 70.

Michigan Agricultural College.—January 26, 1921. Subjects: "Electrochemistry in General" by Mr. W. S. Bersey; "Nodon Valve and Mercury Arc as Rectifying Apparatus"

by Mr. R. S. Backus; "Electricity and Titration" by Mr. Hemans; "Rectification of High-Voltage Alternating Current, and the Precipitation of Solid Particles Out of Gases by Electricity" by Mr. A. R. Carlson. Attendance 32.

School of Engineering of Milwaukee.—A trip to the Allis Chalmers Mfg. Co. Plant was made by the Branch on January 17 and 18. On January 21 a meeting was held at which Mr. A. J. Ackerman gave a short talk on the "Layout of the Plant." Special reports were presented as follows: Products of A. C. Co., by E. T. Webb; Foundry and Pattern Work, by F. J. Renner; Machine Shop, by G. D. Rick; Turbines, by R. W. Groot; Coil Winding, by F. J. Renner; Test Room, by W. A. Smith; Power Plant, by F. J Renner; Illumination of Plant, by L. F. Greve; Accommodations and Labor Conditions, by I. L. Illing; ystems of Engineering Department, by A. J. Ackerman. Attendance 60.

University of Minnesota.—January 7, 1921. Subject: "Features of the New C. M. & St. Paul Electric Locomotive." Speaker: Mr. Q. W. Herschey, Westinghouse Elec. & Mfg. Co. Attendance 103.

University of Missouri.—December 8, 1920. Subject: "Railway Electrification." Speaker: Mr. C. Bethel, Westinghouse Elec. & Mfg. Co. Attendance 54.

January 24, 1921. Subject: "Third Brush Control of Automotive Generators." Speaker: Mr. M. E. Epstein. Attendance 25.

February 7, 1921. Subject: "Opportunities for the Young Engineer in the Telephone Field." Speaker: Mr. R. H. Baxter. Attendance 25.

Montana State College.—December 17, 1920. Paper: "Street Lighting Practise." Speaker: Mr. K. A. Hills, General Electric Co., Butte. Attendance 51.

University of Nebraska.—January 20, 1921. This meeting was given over to a general discussion of summer employment for engineering students. Mr. F. W. Norris and Mr. Fred Acton described the General Electric test course and gave their experiences in Schenectady and Pittsfield. Mr. H. O. Peterson described his summer's work with the Westinghouse Elec. & Mfg. Co. Mr. C. O. Hedges discussed his summer's work with the Minnesota and Ontario Paper Co. Attendance 21.

University of North Carolina.—January 7, 1921. Subject: "The Illuminating Engineer; His Work and How He Does it." Speaker: Mr. James M. Ketch, National Works of General Electric Company. Attendance 45.

January 28, 1921. Subjects: "Thawing With Electricity" by Mr. T. E. Hinson; "Vacuum Tubes" by W. F. Allston; "Wireless Telephony" by T. B. Smiley; "The Edison Industries" by O. W. Freeman. Attendance 30.

University of Notre Dame.—January 17, 1921. Subjects: "Life of John Clerc-Maxwell" by R. A. Black and "Life of Michael Faraday" by W. L. Shilts. Attendance 18.

February 7, 1921. Subjects: "Surveys of the Indiana-Michigan Electric Company" by A. Butine and "Life of Joseph Henry" by J. Huether. Attendance 16.

Ohio Northern University.—January 19, 1921. Subjects: "Submarine Propulsion" by C. E. Walker; "Gyro Compass" by Frank Veverka. Attendance 28.

February 2, 1921. Smoker and talks by faculty. Attendance 50.

Oregon State Agricultural College.—January 12, 1921. Four reels of motion pictures were shown at Y-Hut. Lent by Ford Motor Co. and General Electric Co. Attendance 31.

February 10, 1921. Subject: "Commercial Side of Engineering." Speaker: Mr. A. C. McMicken, of the Portland Railway, Light and Power Company. Attendance 200.

University of Pittsburgh.—January 18, 1921. Election of officers as follows: Chairman, C. W. Merritt; Vice-Chairman, S. L. Pendleton; Secretary, C. B. Nennett. Professor H. E. Dyche gave a short talk on the scope and purpose of the A. I. E. E., with particular reference to the Student Branches. Attendance 25.

January 25, 1921. Talks as follows: "Lubrication, With Particular Reference to Railway Motors" by C. W. Merritt; "An Electrical Device Used During the War for the Detection of Enemy Batteries" by C. A. Anderson; "Safety Measures, and Their Application to the Electrical Industry" by W. H. McCardy. Attendance 24.

February 1, 1921. Talks as follows: "Natural Draft in Boiler Rooms" by R. A. Young; "The Bottle Industry" by Frank Braum; "The Production End of Manufacturing" by Lee S. Pendleton. Attendance 28.

February 15, 1921. Talks as follows: "The Electric Furnace" by E. H. Banks; "The Building and Operation of Oil Fields in Northwestern Pennsylvania" by R. J. Helfrich; "The Engineer in Public Life" by W. J. Zuck. Attendance 24.

Purdue University.—January 11, 1921. Film entitled "The Queen of the Waves" was shown. Attendance 43.

January 22, 1921. Joint meeting with the Indianapolis-Lafayette Section A. I. E. E. Subject: "Professional Men and the American Institute of Electrical Engineers." Speaker: Mr. A. W. Berresford, President A. I. E. E. Attendance 104.

February 1, 1921. Subject: "Explanation and Demonstration of High-Voltage Phenomena." Speaker: Mr. K. B. McEachron. Attendance 406.

Syracuse University.—February 4, 1921. Subject: "Automatic Substations." Speaker: Mr. L. Lyman. Attendance 13.

February 11, 1921. Subject: "Arc Welding." Speaker Mr. Chapin. Attendance 13.

University of Virginia.—January 20, 1921. Subjects: "Colorimetry of Nearly White Surfaces" by Mr. Gilchrist; "Superpower Survey" by Professor Rodman. Attendance 15.

February 10, 1921. The following motion pictures were shown "Big Deeds"; "The King of the Rails"; "Cuba, the Island of Sugar." Attendance 15.

Virginia Polytechnic Institute.—January 24, 1921. Mr. Painter gave a very interesting and instructive talk, based upon practical experience, on "Automatic Starters for D-C. Motors." Mr. Bailey gave a talk, with a practical demonstration, on "The Mercury Vapor Rectifier." Attendance 43.

February 2, 1921. Messrs. Bailey and Grear gave a very interesting lecture, accompanied by slides, on "The Part Electricity Played in the Building and the Operation of the Panama Canal." Attendance 36.

University of Washington.—January 11, 1921. Paper. "The Skagit River Transmission Line." Author: Mr. W. T. Batchellor, Secretary of the Seattle Section A. I. E. E. Attendance 18.

State College of Washington.—January 21, 1921. Election of officers as follows: Chairman, Charles Carpenter; Vice-Chairman, Albert Carlson; Treasurer, Harry Garver; Secretary, Julian Swanson. A moving picture was shown on how the Northeast Static Generator worked. Attendance 38.

West Virginia University.—January 24, 1921. Subjects: "Manufacture of Insulators" by J. L. Hark; "The Oscillograph" by C. M. Hill; "Life of Michael Faraday" by C. A. LaPoe; "Maintenance of Interior Lighting Systems" by H. S. Shinn. Attendance 13.

University of Wisconsin.—January 26, 1921. Business meeting and election of officers as follows: Chairman, R. E Hantzsch; Secretary-Treasurer, R. H. Herrick. Attendance 22.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL *are not acknowledged by personal letter, but unless the applicant is otherwise advised his notice will appear in the coming issue.*

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to EMPLOYMENT SERVICE, 33 West 39th Street, New York City, the employment clearing house of the Societies constituting the Federated American Engineering Societies.

Correspondence relating to replies to advertisements returned to the Bureau will be held in the Bureau for one month only.

Positions of the Bureau are on file in the offices of the member societies of the Federated American Engineering Societies.

OPPORTUNITIES

INSTRUCTORS: All engineers willing to consider teaching positions are invited to register with Employment Service The Bureau has been called upon to fill more positions, varying in grade f rom laboratory assistant to heads of departments in various engineering and technicals school of this country, than it has been able to do from among the men now registered. Blanks for purpose of registration and information regarding the Bureau may be had by addressing W. V. Brown, Manager, 29 West 39th Street, N. Y. City

FIRST CLASS MECHANICS for electrical measuring instruments. Men with executive ability only will be considered. Location Mass. Interview from 9-5 p. m. January 5th, at 29 W. 39th St., N. Y. City. Z-2657.

COMBUSTION ENGINEER. Technical graduate. Two or more years experience, to take charge of tests and investigations of combustion and operating problems. Applicant to state education, training, experience and salary desired. Location Eastern Ohio. Z-2658.

YOUNG MAN WITH TECHNICAL EDUCATION and experience in the design, construction and operation of 2200 volt or standard city distribution lines. Reply giving education experience, references and salary expected. Z-2644.

SALES ENGINEER. Must be a technical graduate with E. E. degree between 22-35 years old. Some sales, testing and repairing experience in small motors desirable. Location New York City. Z-2648.

MECHANICAL ENGINEER for a veneer package plant, steam power plant operation; electrical plant operation and maintenance; woodworking machine maintenance; planer-saws, veneer lathe and clipper, stapling machines, tenoner nailers. Location Ga. X-4.

SALES MANAGER & SALES ENGINEER. Electric heating appliance (especially for domestic cooking) experience desirable. Must have sales manager experience. Application by letter only. Location Wisconsin. X-12.

SALES EXPERT AND SALES PROMOTION MAN with thorough experience in direct and magazine advertising, knowledge printing and electrotype requirement. Able to write "Peppy" copy. Bring sample of work. Electrical experience desirable. Age 26 to 29, not over. X-23.

ELECTRICAL STATION LAYOUT, DESIGNING DRAFTSMEN, experienced men. Preference given technical graduates Location Canada. X-24.

INSTRUCTOR OR ASSISTANT PROFESSOR IN PHYSICS. Must be a graduate engineer not over thirty years old with some teaching experience. Application by letter only. Term will begin January 31, 1921. Location New York City. X-38.

TECHNICAL GRADUATE for Instrument Laboratory. Must have had actual manufacturing experience on electrical measuring instruments. Location New Jersey. X-58.

ASSISTANT PHYSICIST for research work with government. Location New Jersey. X-60.

ELECTRICAL ENGINEER for general instruction work in a correspondence school. Some practical engineering experience required. Application by letter only; give complete information. Location New York City. X-63.

HIGH-GRADE Sales Engineer. Must be live wire—one acquainted with power equipment. Position will pay salary and commission of from eight to ten thousand dollars a year. Prefer man between ages of thirty and forty. No one will be considered whose past sales record does not prove him worth this amount. Position now open. All replies confidential. Location Illinois. X-68.

POWER PLANT SWITCHBOARD OPERATORS with hydroelectric experience. Two years contract. Location Peru. X-84.

ELECTRICAL ENGINEER to install telephones and switchboard. Two years contract. Location Peru. X-85.

CHIEF OPERATING ENGINEER, for two power houses. One plant consisting of five 350-h.p. B. & W. boilers with superheaters and stokers, one 1250-kw. Westinghouse, turbine, one 300-kw. bleeder type Westinghouse turbine, direct current, two compound Corliss type reciprocating pumps for 1200-lb. pressure and one 1250-h. p. compound reciprocating engine in our rolling mill. The other plant has eight 50-h. p. H. R. T. boilers, one Westinghouse high pressure turbine, one De Laval atmospheric pressure turbine, one Curtis mixed pressure turbine, running condensing, a 500-kw. motor-generator set, and two single-cylinder Corliss engines direct-connected to the rolls. Location Connecticut. X-102.

INSTRUCTOR of electricity for Trade School. Should have had several years practical training in the trade; should be well informed regarding the fundamentals of electricity, and must meet the ordinary character requirements. Teaching experience is essential. Will be expected to handle classes in elementary principles of direct and alternating currents and the application, operation, and repair of d-c. and a-c. apparatus. Classes consist of boys fourteen years of age and over, and ex-soldiers sent here under the Rehabilitation Act. The school is in session twelve months in the year. Work to begin on or before February 10th. Location Missouri. X-116.

RECENT ELECTRICAL GRADUATE of a Leading Engineer College wanted for power equipment, development and research in New York City. Two or three years experience in electrical power plants and machines desirable. Work of a consulting nature including supervision of design and the development of control systems and operating methods for machines, switchboards, gas engines and batteries; cost studies, etc. Broad theoretical foundation and acceptable personality are essential. Salary $1800 to $2400 to start, depending on experience. Good opportunity for advancement. Give complete details. Technical and personal. X-143.

EXCELLENT opportunity offered in Shanghai, China for thoroughly experienced designing erecting power plant engineer to handle well-known equipment for well-known established export organization able to finance any installation. Willing to give responsible capable engineer good salary and opportunity to secure up to twenty thousand dollar interest partnership in firm. Only high grade financially able man considered. Give detailed experience references first letter. All confidential. X-142.

MANAGER to take charge of mechanical part of plant manufacturing a line of automobile parts used by manufacturers of cars and trucks, also some machine tool parts, made on Automatic and Hand Screw Machines, Punch Presses, Millers, Drillers, Tappers, Threaders and Polishing Equipment. These parts, are made in quantity lots on above machines. Location Ohio. X-171.

SUPERINTENDENT to have complete charge of a plant manufacturing plants and varnishes. Location Dela. X-181.

SALES EXECUTIVE. Should be familiar with construction and mining machinery of all kinds and should be able to lay out and plan a sales campaign in the West Virginia territory for this class of equipment. Should also have some knowledge of machine tools and electrical equipment but his knowledge need not be too accurate as they already have a high priced electrical engineer. Good salary to right man and in addition a share in the success of the business in addition to salary. Location West Va. X-182.

ARCHITECTS INSPECTOR to brake in on roof work. Estimating. One who knows roof constructions. (specific work)—Estimating of roof coverings. Location New York. X-183.

ELECTRICAL ENGINEER, familiar with maintenance work in publishing plant. Must understand repairs, extension to plant, etc. Must be between 32-38 years old. Application by letter only. X-185.

PROGRESSIVE firm in Middle West needs man to sell high grade electrical device in large units to city gas, coke oven and steel industries. Applicant must be graduate of technical university of good standing. Experience in engineering sales work or in operating in any of above industries will be advantage, but most importance will be attached to well balanced engineering sales ability, desire for hard work and a personality adapted to the exploitation of a proven device. In reply state education training and experience to date and when available. X-190.

ENGINEER for editorial work in electrical periodical. Will be required to look after personal items and also description of electrical apparatus, plants, etc. Application by letter only. X-188.

MEN AVAILABLE

ELECTRICAL ENGINEER, University of Illinois graduate '12, Central station experience on substation design, transmission line specifications and rights, power rates and contracts. Industrial plant experience on power, heat and light installations and superintendence of operation. Desires position of stability and with chances for advancement. E-2517.

PROFESSORSHIP OF ELECTRICAL ENGINEER. Have taught in large university for fifteen years, electromagnetic theory, d-c. and a-c. practise, transient phenomena, radio telegraphy, etc. In charge of important engineering operations during the war (Major). Now on engineering research. Desire suitable position in university with increasing research activities. E-2518.

ELECTRICAL ENGINEER, age 25; married. Two years public utility and one and one half years manufacturing experience, desires sales engineering connection. Location preferred central states. E-2519.

ENGINEER, age 42, large company, salary $7000.00. Wants to join smaller organization. Fourteen years one concern. Twenty years development manufacture sale electrical devices particularly telephones, ignition equipment. Successful inventor having brilliant record developing patent situations and perfecting inventions. Salary secondary, primary requisite congenial connection with real future. E-2520.

ELECTRICAL AND MECHANICAL ENGINEER, technical graduate. Seventeen years general experience in electrical and mechanical engineering, and in charge of construction work in connection with all kinds of power developments, transmission distribution, electric railways and industrial plants, available for new position immediately. E-2521.

DESIGNING ENGINEER, with exceptionally broad experience and highest references on distribution and substation work desires to join a progressive engineering firm and will make a reasonable investment to secure an interest in the business. E-2522.

PLANT SUPERINTENDENT OR FOREMAN. Age 24; married. Experience in large generating plants and substations of nearly every description. At present employed as operator. Would consider operating position with chances for advancement. Location anywhere; South America preferred. Can give best of references. Associate A. I. E. E. E-2523.

GENERAL LINE FOREMAN ten years experience on maintenance and construction installation. Also able to handle chief electrician of mines both a-c. and d-c. Technical training. Can handle large force of men. Married; age 38; available at once. E-2524.

TECHNICAL GRADUATE desires position in radio or electrical laboratory on research and experimental work; radio work preferred. Four years experimental work in laboratory. Now employed as assistant instrument inspector by large public utility company. E-2525.

ELECTRICAL AND MECHANICAL DRAFTSMAN age 33; married. Two years experience on practical and electrical work. Ten years experience in machine design and electrical dreafting. Eight years with present employer. Desires position with chance of advancement. Salary $2500. Location Cleveland. E-2526.

TECHNICAL GRADUATE. Three years in mill, power plant, and electric railway maintenance. Three years teaching both General Science and as head of electrical wiring department of eastern technical school; desires position as works engineer or chief electrician. Prefer eastern states. E-2527.

TECHNICAL GRADUATE, age 35; single, desires position with large company as electrical engineer where a thorough knowledge of electrical construction and motor application and ability to handle men would be appreciated. Salary $3600. Slight knowledge of Spanish. Go anywhere. Employed. Thirty days notice required. E-2528.

MECHANICAL SUPERINTENDENT, chief engineer and master mechanic of textile mills, age 39, married; technical graduate, practical mechanic, thorough knowledge of steam plant economy, electric drives, machinery installations for industrial plants and building construction. First class Massachusetts engineers license. E-2529.

TECHNICAL GRADUATE in electrical engineering desires employment for evenings and spare time, amounting to fifteen hours per week. Will accept any engineering problem or investigation. Have had experience in efficiency investigations of steam plants, electric motor design, radio and telephone engineering. Location St. Louis, Mo. E-2530.

ELECTRICAL ENGINEER GRADUATE, 12 years experience at industrial engineer with large companies. Work includes design of power and industrial plants, supervision and control of plant operations and application of modern engineering methods to standardizing and cheapening production. A. I. E. E. member. E-2531.

TECHNICAL GRADUATE. Is there an opportunity in some electrical engineering department for young man, age 23, protestant, high school graduate business education, I. C. S. graduate in complete electrical engineering, with two months experience as electrician helper, also two years experience as power station and switchboard operator? Associate of A. I. E. E. E-2532.

ELECTRICAL ENGINEER. For sale. Eleven years installation and repair, motors generators, power house, substation, illumination. Capable and efficient man. Sales training. At present electrical superintendent of power and light. Write for details before closing the position you have open. Location no object. Permanent mutual satisfaction only requirement. Best possible references. E-2533.

YOUNG MAN, age 26; single, desires position as electrician or storage battery man with good firm. Four years electrical and six years storage battery experience. Speaks Spanish and has no objection to going outside United States. Can furnish best of references. E-2534.

GRADUATE ELECTRICAL ENGINEER. Ten years practical experience; seven years with large iron mining company. Experienced in design, and operation of steam and water power plants, transmission systems and industrial applications. Now available for position where advancement depends on results obtained. Prefer part outside work. Age 31; married. Best reference. E-2535.

GENERAL ENGINEERING WORK, wanted by member, now employed as investigating engineer by high grade investment securities house in New York. Desires change that will give him active (partial or entire) outside or road work in which he may utilize twelve years experience in sub and central station design, installation and operation, with the country's largest central station company, and four years on hydro and sub-station design and hydraulic investigations and tests with well known engineering company. E-2536.

ENGINEER, technical graduate, experienced in sales, construction, inspection, and advisory work in connection with power stations, electric railways, and large industrial plants, will consider position in advisory capacity with financial investment house or importing or exporting concern. Interview by appointment. E-2537.

ENGINEER, nine years and eight months in last position as chief engineer and superintendent of works in Gas and Electric plant 6000-kw. electric plant and 600,000-cubic-foot gas plant. Open for immediate position in East preferred. Holds 1st class Mass. license. Associate A. I. E. E. Salary $3500. Age 48. E-2538.

OPPORTUNITY wanted with contractors, engineers or public utility. Five years 66 kv. transmission; three years pole lines; eight years industrial installations, illuminations (textile) Technical training, Assoc. A. I. E. E. Fellow Aerial League America. Present employed supervising estimating and. engineering large textile plant. Age 34; Canadian. Prefer any section Canada. Good reasons for changing. References. Present location Mass. E-2539.

ELECTRICAL ENGINEER, age 39, graduate M. I. T. Fifteen years practical experience with all kinds of electrical construction, operation, and maintenance. Deisres position as supervising engineer on construction or electrical engineer for industrial concern. Best references. Salary $2800. E-2540.

ELECTRICAL ENGINEER, 12 years experience including responsible charge of electrical operation and maintenance of large modern power station and sub-stations, electrical design and also construction of power and sub-stations. Application of motors to industrial service including cranes and other material handling devices. E-2541.

ELECTRICAL ENGINEER, age 27. Five years experience in power plant distribution, electric railway and industrial construction, including purchasing, valuation, estimating, draughting and field work, resigning as electrical engineer. Three years experience in metal parts manufacturing including inspection design and development, production and factory systems and accounting, resigning as manufacturing manager. Now with consulting engineering firm but seeks positions in construction or operating fields. Future opportunity primary, salary secondary. New York City or vicinity. E-2542.

ELECTRICAL AND MECHANICAL ENGINEER, age 26, at present employed, desires position with industrial concern or in hydroelectric work. Several years experience in power plant operation, industrial plant layout work and in estimating costs of construction. Available on two weeks notice. Salary expected $250 per month. E-2543.

GRADUATE ELECTRICAL ENGINEER. Six years experience with General Electric Company, including work covered by testing department and switchboard department; also two years additional experience as sales engineer with other companies. Wishes employment with reliable manufacturer on general engineering or research work. E-2544.

TECHNICAL GRADUATE, age 26; married. Four years testing and development engineering with large manufacturer including; 1½ years research work with government. Desires position with growing concern in middle west in research or industrial engineering. Present salary $3000.00. Available immediately. E-2545.

ELECTRICAL DESIGNING DRAFTSMAN wishes position with large manufacturer on special work. Eight years experience in shop mechanical drafting and detailing with railroad and manufacturing plant; three years wiring and general contracting; three years in service and with consulting engineer, telephone, wireless and power house details. Correspondence course in electrical engineering E-2546.

SALES REPRESENTATIVE would like one or two kindred electrical lines for Chicago district. Graduate Wisconsin 1912. Manufacturing, power and commercial experience; past five years as buyer for large mercantile corporation. Sold over $400,000.00 worth of appliances in 1920. Age 33; married. Available at once. E-2547.

ELECTRICAL GRADUATE, age 29, with four years electrical experience in construction, testing, drafting and design, as well as office work, seeks assistantship to engineer in charge of large power system or with consulting engineer engaged along similar lines. E-2548.

TECHNICAL GRADUATE, age 33; married. Eight years operating and supervising large and small coal-carburated water gas properties, manager gas utility, community 7000, one year tool designing automobile plant and one year purchasing and costs auto trailer industry. Desires position with future. Available short notice. E-2549.

GRADUATE ELECTRICAL ENGINEER, two years G. E. test and calculating room. Seventeen years design, construction and operation of power plants, substations, overhead and underground feeder lines on railway electrification. One year superintendent of building construction. Desires permanent sales or executive position with industrial or operating company. E-2550.

ELECTRICAL ENGINEER-PHYSICIST. Engineer in charge of installation of first commercial wireless telephone system in Canada for large hydroelectric company, also in charge of work on protection and on mitigation of inductive interference of telephone lines. Extensive experience in research work, as well as electric power station operation and maintenance. Available on short notice. Desires position with power company or with manufacturer or electrical 'equipment. Location preferred Canada E-2551.

GRADUATE ELECTRICAL ENGINEER, age 30; married. Five years experience including G. E. test, central station test department instructor in radio division of air service and manager of small hydroelectric company. Desires position with hydroelectric company, central station company or firm of consulting engineers. Available on short notice. E-2552.

ENGINEER, eighteen years successful experience in design, manufacture and sales of alternating and direct current motors. Qualified to assume entire charge of business as factory manager, sales or district sales manager. Age 40; American; available March 1st. E-2553.

ENGINEER AND EXECUTIVE. Five years practical experience doing graduate work at present, desires employment during afternoons as assistant to executive. Has specialized on industrial problems of an economic nature. E-2554.

ELECTRICAL ENGINEER, age 32; single. Nine months testing experience with Westinghouse Electric & Mfg. Company. Four years with large electric railway company. Experience includes electrolysis investigation, cable inspection, and solution of problems pertaining to electric traction and power plant operation. E-2555.

ELECTRICAL ENGINEER, thirteen years experience in manufacture, testing and designing of alternating current motors and generators. At present in charge of electrical and mechanical design of alternating and direct-current motors and generators. Desires to connect with one of smaller progressive companies. Available in sixty days. E-2556.

ELECTRICAL ENGINEER, desires responsible position with central station. Ten years experience on large systems, systems power stations, substations, transmission, and a-c, and d-c. distribution. Cansup ervise the making of plants and handle construction and operation. Associate A. I. E. E. and technical graduate. Best references from former employers. E-2557.

EXPORT ENGINEER. Graduate electrical and mechanical engineer desires connection with firm, that needs man acquainted, through ten years experiences with electrical manufacturers material, and also acquainted with languages and social conditions of Scandinavian countries. At present in charge of electrical department, with large contracting and designing engineering company. E-2558.

YOUNG MAN, technically trained in electrical engineering. Four years practical experience in repair works. Thorough knowledge of Spanish. Has travelled in Latin American countries. Ambitious and willing worker. Age 22; single. Will accept position as assistant to electrical engineer, interpreter or translator. Location no object. E-2559.

GENERAL OR WORKS MANAGER. Mechanical and electrical engineer. 15 years executive industrial experience in management, sales, finance, factory organization and quantity production. Can handle old established or develop new manufacturing propositions from raw materials to the marketing of finished product. E-2560.

ELECTRICAL ENGINEER. Yale A. B. Massachusetts Institute of Technology, S. B. in electrical engineering. Harvard S. B. E. E. Nine years experience in designing and construction of steam railway electrification, power stations, substations and high tension transmission lines. E-2561.

GENERAL MANAGER of utilities, at present operating twelve electric, eight ice, two water works properties, desires change because individual properties are being sold. Age 37; married, technically trained, exceptionally competent in manufacture and sale of ice. Salary $7500. E-2562.

YOUNG MECHANICAL and electrical engineer with 1½ years experience in industrial and power plant work desires to make connection with industrial, power plant, construction or general consulting concern. Training largely executive in nature. E-2563.

EXPERIENCED ELECTRICAL ENGINEERING INSTRUCTOR a-c. and d-c. theory and laboratory and electrical transmission, B. S. in E. E. 1917. Three years experience in power plants Signal Corps and assistant to consulting engineer, one year teaching. Desires associate professorship in recognized engineering college beginning Sept. 1921. E-2564.

PUBLIC UTILITY MANAGER, electrical engineer, member A. I. E. E., American. Broad experience construction, operation and management light, power and street railways, steam and hydroelectric. Available at once, this country or Spanish America. Thorough knowledge of Spanish. E-2565.

ELECTRICAL SUPERINTENDENT. Services available on short notice, power house, substation, industrial plants, distribution overhead and underground, construction or maintenance. 22 years experience; age 42; location anywhere. At present employed but looking for permanent location. E-2566.

ENGINEER EXECUTIVE, university graduate, electrical, mechanical, sound business training. Construction, sales and purchasing experience. Until recently in charge of exports New York office well known foreign house of contractors merchants, managers. Good knowledge domestic industry and foreign conditions. Associate A. I. E. E. and A. S. M. E. Age 33; married. Good references. E-2567.

ELECTRICAL ENGINEERING GRADUATE, 1919 B. S. Age 23; wishes to become associated in work of commercial character with concern handling electrical equipment. General Electric test; excellent English and Russian, full of energy and aflame with ambition. Entrance salary dependent on future possibilities. Available on short notice. East preferred. E-2568.

GRADUATE MECHANICAL ELECTRICAL ENGINEER. Experience; two years in radio research; two years in radio design in government service; two years in manufacture of radio apparatus; one year in engineering sales of industrial equipment. One year as plant manager of organization building $500,000 worth of radio and similar equipment per year. Available after March 1st, for production or engineering sales work. E-2569.

YOUNG RAILROAD MAN, desires position as superintendent or master mechanic with small street or interurban railway property. 8 years experience in construction, maintenance and operation, 5 of which were spent with two leading New York rapid transit systems. At present employed as chief electrician of large power company but desires to return to work in which he has previously specialized. References. E-2571.

RESEARCH AND DEVELOPMENT ENGINEER, age 27; married; associate A. I. E. E.; college graduate. Six years of research and development both electrical and mechanical. Capable of handling independent investigations and getting results. Prefer position with manufacturing concern where experience can be applied to production problems. Acquainted with electrical machinery and storage batteries. Minimum salary $2400. E-2572.

GRADUATE ELECTRICAL ENGINEER, age 31. One and one-half years G. E. test; one year G. E. radio research; three years broad electrical experience; radio experience in the army; and two years teaching electrical engineering in western university. Desire teaching position in university or engineering school. E-2573.

GRADUATE ELECTRICAL ENGINEER, 1917, Associate A. I. E. E. age 26; married. Two years experience as manager of steam plant desires position as assistant to electrical engineer or with electrical contractor. Present salary $2200. References furnished on request. E-2574.

ELECTRICAL ENGINEER, nine years experience in design and operation of electric light power systems, desires position with central station company or large engineering firm. Can handle men. Experience includes power stations, substations, transmission, and a-c. and d-c. distribution, overhead and underground. University graduate; married. E-2575.

ENGINEER. Associate A. I. E. E. age 32; married. Fourteen years practical electrical and steam experience construction, testing, operation, and maintenance. Technical education self attained. Desire charge of electrical plant, transmission lines, wiring, etc. Location West. E-2576.

TECHNICAL GRADUATE, American. At present in charge of operation, construction and maintenance of electrical and mechanical equipment of large mine in Spanish America. Available within sixty days. Married. Speaks Spanish fluently. Present salary $4000. Would consider similar position with industrial mining or central station anywhere. E-2577.

ELECTRICAL ENGINEER, thoroughly equipped for organization and direction of research and development of electrical apparatus or materials, having recently completed notable work in connection with automotive, magneto and ignition equipment. E-2578.

ELECTRICAL ENGINEER, 1917 Illinois electrical engineering graduate, age 28. Sound business training; six years of railway, power shop, and distribution experience. Salary $200.00 per month. E-2579.

TECHNICAL GRADUATE, with ten years experience in field, office, and laboratory engineering with power plant equipment and electrical precipitation processes. Sales and patent experience. Desires position as development engineer or in executive capacity. E-2580.

YOUNG ELECTRICAL ENGINEER, age 23; graduate of 1919, desires position in or near New York City. Experience includes G. E. test course (7 months) one-half year of central and substation testing and some teaching. E-2581.

ELECTRICAL ENGINEER, on month's notice. Desires position as sales or service engineer. Seven years experience on actual construction, installation and testing work. Broad knowledge of general testing and meter laboratory work. Degree E. E. Desires territory near Indiana. E-2582.

PRODUCTION MANAGER, assistant works manager. Graduate electrical engineer. Age 26; married. Former Captain Engineer Reserve Corps. Desires position offering an opportunity for advancement. At present production manager of a plant of 50,000 unit capacity. Middle Western location preferred, but not essential. E-2583.

TECHNICAL SCHOOL graduate, age 23; with three years college training towards degree in Electrical Engineering; also experience as assistant superintendent in vocational school electricity and machine shop practise, wishes electrical installation, or work not too confining; preferably outside. Any location considered. Preferably eastern United States. E-2584.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute Records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1. Leo Arany, Room 201, Parkway Bldg., Broad & Cherry Streets, Philadelphia, Pa.
2. De Los De Tar, 411 East 15th Street, Kansas City, Mo.
3. Richard H. Gust, Mountain States Tel. & Tel. Co., Pocatello, Idaho.
4. Alex. E. Keith, 138 Elm Street, Hinsdale, Ill.
5. H. S. Logan, 215 15th Street, Seattle, Wash.
6. Harry I. Shire, 1310 Majestic Bldg., Detroit, Mich.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED FEBRUARY 16, 1921

ADAMS, ALLEN A., Asst. Supt., U. S. Electrical Mfg. Co.; res., 1021 W. 91st St., Los Angeles, Calif.

ALEXANDER, PETER P., Electrical Engineer, General Electric Co.; res., 16 Baker St., Lynn, Mass.

ALLEN, ALEX D., Engineer, Allen Engineering Co., 41 King William St.; res., Y. M. C. A., Hamilton, Ont.

ALLEN, CHARLES S., Engineer, Ingersoll-Rand Co., Phillipsburg, N. J.; res., 909 Northampton St., Easton, Pa.

ALLEN, JOHN E., Asst. to Testing Engineer, Pennsylvania Water & Power Co.; res., 2517 Garrison Ave., Baltimore, Md.

ANDREWS, ALVIN G., Electrolysis Engineer, Michigan State Telephone Co.; res., 76 Churchill Ave., Detroit Mich.

APOSTOLOU, JAMES, Engineer, Westinghouse Elec & Mfg. Co., E. Pittsburgh; res., 516 Holmes St., Wilkinsburg, Pa.

*ARMSTRONG, MORRIS S., Service Dept., Westinghouse Elec. & Mfg. Co., Philadelphia, res., 143 Walnut St., Jenkintown, Pa.

AYLES, JESSE A., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston 8, Mass.

BALHATCHET, HAROLD S., Vice-President, Benjamin Electric Mfg. Co. of Canada, Ltd., 17 Charlotte St., Toronto, Ont.

BARNES, IRVING T., Electrical Draftsman, Edison Electric Illuminating Company, 39 Boylston St., Boston; res., 7 Chestnut St., Waverly 79, Mass.

BEEDLE, A. L., President, Beedle Equipment Co., 1309 Union Trust Bldg., Cincinnati, Ohio.

BEHNER, LEROY, Asst Supt., Telegraph & Signals, Pennsylvania System, Central Region, 1502 Chamber of Commerce Bldg., Pittsburgh, Pa.

BERTON, PHILIP L., Telephone Engineer, Northern Electric Co. Ltd.; res., 41 Victoria St., Montreal, Quebec.

*BIGGERS, JESSE D., Electrical Engineer, Oil Cities Electric Co., Breckenridge, Texas; Norman, Okla.

BLAISDELL, COLBORN E., Meter Tester & Inspector, Twin State Gas & Electric Co., Dover, N. H.; res., York Village, Maine.

*BLOSS, ERNEST K., Railway Section, General Engg. Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 382 S. Negley Ave., Pittsburgh, Pa.

*BOCHER, HERMAN W., JR., Instructor of Electricity, School of Engineering of Milwaukee; res., 765 Marshall St., Milwaukee, Wis.

BODICKY, ANDREW, Transformer Tester, Wagner Electric Mfg. Co., 6400 Plymouth Ave., St. Louis, Mo.

BOODY, PERCY L., Foreman, Electrical Construction, Twin City Rapid Transit Co.; res., 4311 E. Lake St., Minneapolis, Minn.

*BOOTHROYD, CLAUDE OLIVER, Power Plant Engineer, Hospital Good Shepard; res., 510 E. Jefferson St., Syracuse, N. Y.

BOYER, WILLIAM H., Engineer, Cable Testing, The Pacific Tel. & Tel. Co.; res., 1892 E. Yamhill St., Portland, Ore.

BRIGHT, JACOB, Chief Clerk, General Supt. Telegraph, Pennsylvania System, 168 Broad St. Station, Philadelphia, Pa.,

BROWN, ELLSWORTH A., Chief Electrician, Halcomb Steel Co.; res., 631 Onondaga Ave., Syracuse, N. Y.

*BROWN, JOHN D., Electrical Engineer, Fletcher-Thompson, Inc.; res., 1 East St., Bridgeport, Conn.

BROWN, WILLIAM J., Tester, Georgia Railway & Power Co.; res., 327 Spring St., Atlanta, Ga.

BRUNS, HARRY, Electrical Gunner U. S. Navy, Testing Laboratory Bldg., No. 22, Navy Yard, New York; res., 290 Nassau Ave., Brooklyn, N. Y.

BRUSH, CHARLES F., JR., Electrical Engineer, 3701 Euclid Ave., Cleveland, Ohio.

*CALHOUN, ERNEST N., Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

*CANNON, WILLIAM D., Research Graduate Assistant, University of Illinois, Urbana, Ill.

CAPWELL, ELMER A., Master Mechanic, Coventry Co., Anthony, R. I.

CARROTHERS, JOHN W., Draftsman, Hans von Unwerth, 505 Finance Bldg.; res., Y. M. C. A., Kansas City, Mo.

*CARROW, HAROLD G., Asst. Electrical Engineer, Michigan Public Utilities Commission; res., 1600 Vermont Ave., Lansing, Mich.

*CARTER, PHILIP S., Engineer, Radio Corporation of America, 233 Broadway, New York, N. Y.

CASSELBERRY, CHAS. L., Foreman, New Construction, Halcomb Steel Co.; res., 101 Elk St., Syracuse, N. Y.

CHADWICK, WALLACE L., Plant Engineer, California Alkali Co., Cartago, Inyo County, Cal.

CHELTON, HENRY C., Contractor, Safety Electric Service Co., 423 W. Franklin St., Baltimore, Md.

CHURCHLAND, JOHN, Manager, Construction Dept., Electric Supply Co., 781 Granville St., Vancouver, B. C.

COGAN, MYLES M., Engineering Dept., New England Tel. & Tel. Co., Boston; res., 47 Woodbine Road, W. Roxbury, Mass.

COTTERMAN, LEO K., Treasurer & Manager, Philippine Acetylene Co., Manila, P. I.

COTTING, PAUL M. L., Electrical Draftsman, Charles H. Tenney & Co., Boston; res., 30 Hume Ave., Medford, Mass.

COWIE, HUGH, Testing Dept., Canadian General Electric Co., Ltd.; res., 462 Sherbrooke St., Peterboro, Ont.

COX, ARTHUR S., Electrical Engineer, Messrs. Turner, Hoare & Co., Ltd., Bombay, India.

CROLY, ROBERT M., Power House, Pennsylvania R. R., Long Island City; res., 215 W. 21st St., New York, N. Y.

CRONKHITE, MINTON, Salesman, 115 Worth Street, New York, N. Y.

CROSS, CHARLES H., Manager, Village of Solvay Electrical Dept., 1100 Woods Road, Solvay, N. Y.

CUNNINGHAM, PAUL D., Tester, Georgia Railway & Power Co.; res., 505 Highland Ave., Atlanta, Ga.

DARLING, JOHN A., Asst. Chief System Operator, Edison Electric Illuminating Company of Boston, 776 Summer St., So. Boston; res., Dorchester, Mass.

DAVIS, R. J., District Sales Agent, Century Electric Co., St. Louis, Mo.; 171 2nd St., San Francisco, Calif.

*DAVIS, ROBERT L., Lecturer, Electrical Engineering Dept., Queens University, Kingston, Ont.

DAWSON, HILARION D., Engineering Dept., Westinghouse Elec. & Mfg. Co., East Springfield Plant; res., Y. M. C. A., Chestnut St., Springfield, Mass.

DEGNAN, ROBERT E., Inspector of Electrical Conductors, Dept. of Water Supply, Gas & Electricity, City of New York, Municipal Bldg., New York, N. Y.

DENNISON, KENNETH REID, Electrician, Canadian Westinghouse Co., Ltd., 366 Adelaide St. West, Toronto, Ont.

DICKINSON, WILBUR K., Instrument Transformer Designing Engineer, General Electric Co., Lynn, Mass.

DOLE, SANFORD B., Switchboard Engineer, The Pacific Tel. & Tel. Co., San Francisco; res., 842 Acacia Drive, Burlingame, Calif.

DOYEN, DANIEL, Engineer, Appareils "Delco," Accumulateurs Prest-O-Lite, 148 Avenue de Malakoff, Paris, France.

DUNKLE, CLARENCE C., Electrical Foreman, Bunker Hill & Sullivan Mining & Consolidated Co.; res., 701 McKinley Ave., Kellogg, Idaho.

ELLIGERS, JOHAN, Machine Tender, Salt River Valley Water Users Association, 1131 Central Ave. North, Phoenix, Ariz.

ELLINWOOD, RALPH W., Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

ELLIOT, ANDREW H., Local Supt., Northern Ontario Light & Power Co., Matabitchowan; res., Montreal River, Ont.

*ENGLE, MELVIN D., Engineer, Consolidated Gas, Electric Light & Power Co.; res., 659 W. Franklin St., Baltimore, Md.

ENGLISH, G. H., Sales Engineer, The Leeds & Northrup Co.; res., 6709 McCallum St., Philadelphia, Pa.

ESTES, MARION S., Asst. Power Engineer, Denver Gas & Electric Co., 900 15th St., Denver, Colo.

EUSTON, JACOB H., Bureau of Commercial Economics, 122 S Michigan Ave., Chicago, Ill.

FARISS, TOM MCLEE, Supervision of Telegraph Service, Amer. Tel. & Tel. Co., 823 Boatmen's Bank Bldg., St. Louis, Mo.

FERGUSON, JOHN R., Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

*FERLIC, ANDREW J., Testing Dept., Westinghouse Electric & Mfg. Co., E. Pittsburgh; res., Cuddy, Pa.

FLOCKART, DERWENT P., 58 Broadway, East Camberwell, Victoria, Australia.

FONSECA, ARTHUR W., Transmission Engineer, The Pacific Tel. & Tel. Co., Telephone Bldg., Portland, Ore.

FONSECA, EDWARD L., Engineer, H. A. Wilson Co., 97 Chestnut St., Newark, N. J.

FORBES, ANDREW, Electrician, Portland Railway, Light & Power Co., Electric Bldg., Portland, Ore.
FRASER, WILLIAM W., Patent Dept., General Electric Co., Schenectady, N. Y.
FRYER, ROY C., Supt. of Meters, Union Gas & Electric Co., 4th & Plum Sts., Cincinnati, Ohio.
FUJIMOTO, TADASHI, Asst. in Physics Dept., Scott Laboratory, Wesleyan University, Middletown, Conn.
GARDNER, WILLIAM G., Erecting Engineer, General Electric
GARWIN, ROBERT, Electrical Engineering Student, St. Claire Ave. & 103rd St.; res., 773½ E. 103rd St., Cleveland, Ohio.
GAVIN, ROBERT G., Electrician, Northern Electric Co., Montreal, Que.
*GEORGE, BEAUFORD J., Engineer, Overhead Dept., Kansas City Power & Light Co.; res., 3617A Wyandotte Ave., Kansas City, Mo.
GEORGE, ROBERT B., Associate Prof. of Electrical Engineering, Mississippi Agricultural College, Agricultural College, Miss.
GERMAIN, LEON W., Division Plant Engineer, American Tel. & Tel. Co., 311 W. Washington St., Chicago, Ill.
GILBERT, FREDERICK W., Electrical Engineer, McIntyre Porcupine Mines, Schumacher, Ont., Canada.
GILLMORE, REGINALD W., Student Engineer, General Electric Co., W. Lynn; res., 107 Jersey St., Boston 17, Mass.
*GILT, CARL M., Electrical Engineer, Lighting Dept., General Electric Co.; res., 103 Edward St., Schenectady, N. Y.
*GISH, HENRY J., Electrical Engineer, St. Joseph Railway, Light & Power Co., St. Joseph, Mo.
GLENNIE, ALFRED G., Chief Electrician, Hartford Rubber Works Co., Hartford, Conn.
*GOLJENBOOM, GEORGE, Electrolysis Engineer, The Milwaukee Electric Railway & Light Co.; res., 184 Knapp St., Milwaukee, Wis.
*GOODALE, JOSIAH E., Junior Engineer, New York & Queens Electric Light & Power Co., Bridge Plaza, Long Island City, N. Y.
Co., Philadelphia, Pa.; res., 3114 West Ave., Newport News, Va.
GRADY, JAMES M., Asst. Engineering Manager, Industrial Bearing Division, General Motors Corp., 100 E. 41st St., New York, N. Y.; res., E. Orange, N. J.
GRAY, CECIL, Salesman, Westinghouse Electric & Mfg. Co., 121 E. Baltimore St., Baltimore, Md.
GREBEL, VILAR E., In charge of new Electrical Work, Northern Paper Mills, 640 S. Webster Ave., Green Bay, Wis.
GRIEST, GEORGE W., Chief Operator, Edison Co., Conestoga Bldg., Lancaster, Pa.
GRUSH, HENRY G., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.
HACKETT, J. HENRY, Transmission & Distribution Engineer, Philadelphia Electric Co., 10th & Chestnut Sts., Philadelphia, Pa.
HACKETT, JOHN W., Sales Engineer, The Okonite Co., 501 Fifth Ave., New York, N. Y.
HALLETT, WILLIAM S., General Supt., Northern Ontario Light & Power Co., Cobalt, Ont.
HAMMERTON, WILLIAM G., Maintenance & Power Inspector, Toronto & Niagara Power Co.; res., 317A Roncesvalles Ave., Toronto, Ont.
HAWLEY, DEXTER R., Supervisor of Toll Lines, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.
HAWLEY, HOWARD B., Supt., Meter Dept., Northern Ontario Light & Power Co., Ltd., Cobalt, Ont.
*HAWLK, CHESTON R., Electrical Draftsman, Leeds & Northrup Co.; res., 3235 N. Carlisle St., Philadelphia, Pa.
HAWTHORNE, JACK A., Electrical Inspector, The New York Board of Fire Underwriters, 123 William St., New York; res., Manhattan Beach, N. Y.
HEALEY, ROLLA E., Facilities Engineer, New England Tel. & Tel. Co., Boston; res., Glenwood Road, Needham, Mass.
HEIDENREICH, GEORGE E., Electrical Engineer, Warren D. Spengler, 200 Marshall Bldg., Cleveland, Ohio.
*HEINEMANN, J. ROBERT, Head of Testing Dept., General Electric Co.; res., 1502 Union St., Schenectady, N. Y.
*HILL, WALTER L., Electric Distribution Dept., Pacific Gas & Electric Co.; res., 415 S. 13th St., San Jose, Calif.
HOLLENDER, WILLIAM, Student in Automatic Telephony, New York Edison Co.; res., 99 St. Marks Place, Brooklyn, N. Y.
HORLEY, ROBERT E., Electrical Engineer, Pirelli General Cable Works, Western Shore, Southampton, England.
HOWARD, JAMES P. G., Electrical Draftsman, Light & Power Dept., City of Winnipeg; res., 654 Langside St., Winnipeg, Man.
*HUBBARD, FREDERICK W., Engineer, Railway Equipment Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 382 S. Negley Ave., Pittsburgh, Pa.
HUEY, RAYMOND W., Testing Dept., Georgia Railway & Power Co.; res., 214 E. Pine St., Atlanta, Ga.
*HUMPHREY, CHARLES G., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway; res., 612 W. 114th St., New York, N. Y.
ISLEY, CARY T., Local Superintendent, Yadkin River Power Co., Wadesboro, N. Y.
*JACOBS, ARTHUR R., Supply Dept., General Electric Co., Monadnock Bldg., Chicago, Ill.
JAMES, CARL P., Head of Electrical Division & Asst. to Head of Power Division, DuPont Chemical Co.; res., 611 Geddes St., Wilmington, Del.
JEMMETT, DOUGLAS M., Asst. Professor of Electrical Engineering, Queens University, Kingston, Ont.
JETT, CHARLES H., Chief Operator, Postal Telegraph Cable Co.; res., 1241 Lincoln St., Denver, Colo.
JOHNSON, HERBERT M., Head, Meter Dept., New England Power Co.; res., 427 Hamilton St., Worcester, Mass.
JONES, GERALD L., Testing Dept., Canadian General Electric Co.; res., 516 Charlotte St., Peterboro, Ont.
JONES, HERNDON C., Electrician, Weirton Steel Co., Weirton; res., Hollidays Cove, W. Va.
KALBACH, STANLEY M., Supt. of Electrical Installation & Contractors, Stone & Webster, Inc.; res., 1410 Madison Ave., Baltimore, Md.
*KAPP, CECIL A., Associate Professor in charge of Co-ordination, Georgia School of Technology, Atlanta, Ga.
KEELEY, HENRY J., Night Chief Operator, Postal-Telegraph Cable Co.; res., 1317 E. 18th Ave., Denver, Colo.
*KENNEDY, THOMAS W., Power & Mining Dept., General Electric Co.; res., 13 N. Wendell Ave., Schenectady, N. Y.
*KINLEY, CLIFFORD B., Transmission Man, American Tel. & Tel. Co., Nasby Bldg., Toledo, Ohio.
*KINNARD, ISAAC F., Research Engineer, Westinghouse Elec. and Mfg. Co., E. Pittsburgh; res., Westinghouse Club, Wilkinsburg, Pa.
*KLASS, FRED, Student Engineer, General Electric Co.; res., 1502 Union St., Schenectady, N. Y.
KLINGMAN, LOREN E., Foreman, Meter Test, General Electric Co.; res., 301 E. Pontiac St., Ft. Wayne, Ind.
KROUSS, WILLIAM A., Engineering Dept., General Electric Co., Oliver Bldg.; res., 5815 Rural Ave., Pittsburgh, Pa.
LAKE, CHARLES J., Special Tester, Philadelphia Electric Co., 266 South 11th St., Philadelphia, Pa.
LANG, EDWARD H., Supt., Pittsburgh Transformer Co.; res., 3903 Wilksboro Ave., N. S. Pittsburgh, Pa.
LATHOROP, WILLIAM F., Testing Dept., General Electric Co., Schenectady, N. Y.
LAWTON, LEWIS C., Cost Examiner, Installation Div., The Philadelphia Electric Co., 226 S. 11th St., Philadelphia, Pa.
LE COULTRE, ELIE P., Ingegnere Capo of the Sociata Meridionale di Elettricita, via P. E. Imbrani, 39 Napoli, Italy.
LEMMON, WALTER S., Sales Engineer, S K F Industries, Inc., 165 Broadway, New York, N. Y.
LEMON, ALONZO L., Power and Mining Engineering Dept., General Electric Co., Schenectady, N. Y.
LEONARD, WILLIAM E., Equipment Engineering Dept., New England Tel. and Tel. Co., Boston; res., 2 Nursery St., Salem, Mass.
*LOEWENTHAL, GEORGE G., Electrical Merchandising and Contracting, 618 N. Main St., Pueblo, Colo.
LONG, RALPH E., Graduate Student, Supply Sales Course, Westinghouse Elec. and Mfg. Co., E. Pittsburgh, Pa.
LOUGHEAD, ROBERT C., Chief Engineer, Michigan Inspection Bureau, 1200 Real Estate Exchange, Detroit, Mich.
*LOWCOCK, HENRY, Wilkinsburg Hotel, Wilkinsburg, Pa.
LUEKING, LANCELOT L., Division Plant Engineer, Long Lines Dept., Amer. Tel. and Tel. Co., 823 Boatmen's Bank Bldg., St. Louis, Mo.
LUENEBRINK, CHESTER F., Transformer Tester, Wagner Electric Mfg. Co.; res., 2504 University St., St. Louis, Mo.
*LUNEY, OSWALD S., Engineer, Hydro-Electric Power Commission of Ontario; res., 5 McGrail Ave., Niagara Falls, Ontario.
*LURIE, SIDNEY J., Asst. Engineer on Equipment Design, Delta Star Electric Co.; res., 109 E. 59th St., Chicago, Ill.
LYNDE, WALTER L., Equipment Attendant, American Tel. and Tel. Co., Beaver Dam, Ohio.
MACALISTER, JAMES E. D., 754 Drexel Blvd., Detroit, Mich.
MACDONALD, RUSSELL R., Asst. Designer, Philadelphia Electric Co., Penn. R. R., Broad St. Station, Philadelphia, Pa.
MAHER, HENRY C., Salesman, International General Electric Co., 120 Broadway, New York, N. Y.

*Marsh, E. L., Erecting Engineer, Construction Dept., General Electric Co., Schenectady, N. Y.; Marion, Mass.
Marson, Arnaldo, Leading Structural Draughtsman, New York Edison Co.; res., 118 E. 18th St., New York, N. Y.
Mason, Roy W., Electrical Engineering Dept.. General Electric Co.; res., 28 Stratford Ave., Pittsfield, Mass.
Matsuno, Shigeo, Electrical Engineer, Takata and Co., 50 Church St., New York, N. Y.
Maxwell, Marshall P., President, Maxwell Engineering and Mfg. Co., Eastern Sales Manager, R. Thomas and Sons Co., 61 Broadway, New York, N. Y.
Mayer, Geo. H., Supt. of Telegraph, Soo Railway Co., Stevens Point, Wis.
McDonald, Gordon R., Engineer, Switchboard Dept., General Electric Co.; res., 211 Union St., Schenectady, N. Y.
McDonald, John A., Mgr., Mfg. Dept., Capital Electric Co.; res., 855 So. 6th East St., Salt Lake City, Utah.
McEver, William L., Professor, Georgia School of Technology, Atlanta, Ga.
McFerrin, Albert B., Tel. and Tel. Installer, Penn. R. R., St. Louis, Mo.; res., 1230 Walnut St., Terre Haute, Ind.
McGill, Charles S., Electrical Supt., Wilmington & Philadelphia Traction Co., Wilmington, Del.
McKamy, William E., Superintendent, T. H. McKenney, Inc., Atlanta, Ga.
McWilliam, Cecil E., Testing Dept., Canadian General Electric Co.; res., 209 Murray St., Peterboro, Ont.
Miles, Frank T., Branch Manager, The Beedle Equipment Co., 509-10 Lemcke Bldg., Indianapolis, Ind.
Milford, William J., Foreman, Electrical Construction, Tacoma Ry. & Pr. Co.; Puget Sound Elec. Ry.; Puget Sound Pr. & Lt. Co.; res., 1717 S. 7th St., Tacoma, Wash.
*Millard, Arthur M., Engineer's Asst., Southern New England Telephone Co.; res., 115 Howe St., New Haven, Conn.
*Miller, LeRoy J., Partner & Salesman, Miller-Lyke Co., 823 Flatbush Ave.; res., 284 Ocean Parkway, Brooklyn, N. Y.
Milne, Gordon R., Construction Engineer, T. A. Edison, Inc., W. Orange; res., 593 N. 8th St., Newark, N. J.
Moffitt, L. E., Asst. Supt. of Distribution, Brooklyn Edison Co., 14 Rockwell Place, Brooklyn, N. Y.
Moore, Ernest R., Engineering Dept., New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.
*Moore, Harold S., Testing Dept., General Electric Co.; res., 205 Seward Place, Schenectady, N. Y.
Moore, Harry L., Student, School of Engineering; res., 545 Market St., Milwaukee, Wis.
*Moore, Willard S., Research Engineer, Conveyor Belt Dept., U. S. Rubber Co., 1790 Broadway, New York, N. Y.
Mortimer, Ernest A., Asst. Manager, Companhia Telephonica, Rio de Janeiro, Brazil, S. A.
Mosher, Maurice E., Service Dept., Cutler-Hammer Mfg. Co., 50 Church St., New York, N. Y.
Muller, George G., Engineering Dept., Western Electric Co., 463 West St., New York; res., 594 Park Place, Brooklyn, N. Y.
Munro, Peter B., Testing Dept., Canadian General Electric Co.; res., 462 Sherbrook St., Peterboro, Ont.
Murray, Edwin R., Sales Specialist, Western Electric Co., San Francisco; res., 1222 Versailles Ave., Alameda, Calif.
*Nalle, John M., Jr., Asst. Electrical Engineer, Panama Canal, Balboa Heights, C. Z.
Nealis, F. H., Salesman, Westinghouse Elec. & Mfg. Co., 1107 Traction Bldg., Cincinnati, Ohio.
Nelson, Rufus L., Power Engineer, Utica Gas & Electric Co., 222 Genesee St., Utica, N. Y.
*Neumann, Warren R., Instructor in Electrical Engineering, University of Kansas, Lawrence, Kans.
*Newell, Hobart H., Electrical Engineer, Westinghouse Elec. & Mfg. Co., Research Bldg., E. Pittsburgh, Pa.
*Noddins, Raymond W., Manager, Easton Ind. Tel. Co., Orleans, Mich.
*Nottingham, Wilbur F., Asst. Electrical Engineer, Great Northern Power Co., Duluth, Minn.
*Olson, Richard H., Partner, Pearson & Olson, 1420 Fisher Bldg., Chicago, Ill.
Orsoe, John J., Partner, P. A. Storage Battery & Electric Co., 266 Madison Ave., Perth Amboy, N. J.
Ostroll, Harry, Student, Brooklyn Polytechnic Institute; res., 1851 85th St., Brooklyn, N. Y.
Papineau, Denis V., Telephone Engineer, Northern Electric Co., Ltd., Montreal; res., 793A Champagneur Ave., Outremont, P. Q., Canada.
Payne, Walter B., Supt., Repair Dept., Georgia Railway & Power Co.; res., 152 W. Merritta Ave., Atlanta, Ga.
Pendery, Horace F., Asst. Manager, The Beedle Equipment Co., 1309 Union Trust Bldg., Cincinnati, Ohio.
Pennock, Frederick W., Vice-President & General Manager, Cleaton Co. (Canada), Ltd., Coristine Bldg., Montreal, Que.
*Peters, Oscar F., Draftsman, Krantz Mfg. Co., 160-166 7th St., Brooklyn; res., 300 W. 17th St., New York, N. Y.
*Peterson, Paul, Electrical Engineering Dept., Hudson Coal Co.; res., 921 Quincy Ave., Scranton, Pa.
Phillips, Leon L., Division Transmission Engineer, The Pacific Tel. & Tel. Co., Telephone Bldg., Portland, Ore.
Pomares, Marino L., Vice-President, Austin & Moore Inc., 87 Wilbur Ave., Long Island City, N. Y.
Quinneen, Charles R., Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.
Rainey, Punderson A., Electrical Engineer, Pennsylvania System, 438 Broad Street Station, Philadelphia, Pa.
Ralston, Emmet G., Chief Electrical Engineer, Indianapolis Light & Heat Co., 48 Momument Place, Indianapolis, Ind.
*Randa, Charles E., Telephone Equipment Engineer, Western Electric Co., Hawthorne; res., 3839 W. 26th St., Chicago, Ill.
Ransom, Paul, Electrical Engineer, Utah Apex Mining Co., Bingham Canyon, Utah.

ASSOCIATES REELECTED FEBRUARY 16, 1921

BEHNKE, R. E., Asst. Electrical Engineer, Dwight P. Robinson & Co., Inc., Grand Centrral Palace; res., 2835 Marion Ave., New York, N. Y.
BLISS, ERNEST F.; East Moriches, Long Island, N. Y.
HAISLIP, RICHARD A., Telephone Engineer, Dept. of Development & Research, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
JONES, JULIAN D., Supt., Telegraph & Signals, Eastern Region, Pennsylvania System, Broad Street Station, Philadelphia, Pa.
LEET, ARTHUR W., Transportation Engineer, Mercury Mfg. Co., 816 Union Trust Bldg., Detroit, Mich.
STEPHENS, HERBERT C., Chief Engineer, The Electric Motor & Repair Co., 60-62 Iron St., Akron, Ohio.

MEMBERS ELECTED FEBRUARY 16, 1921

GRAHAM, WARREN C. S., Consulting Engineer, Calle Rividavia 770, Buenos Aires, Argentina, S. A.; res., 5317 Magazine St., New Orleans, La.
HARRISON, JOHN A., Traffic Engineer, The North Electric Mfg. Co.; The Lime Tel. and Tel. Co., 122 So. Elizabeth St., Lima, Ohio.
JONES, WILLIAM S., Electrical Engineer, Bureau of Yards and Docks, Navy Dept., 2943 Navy Bldg., Washington, D. C.
MALING, SILAS Y., Deputy City Electrical Engineer, Municipal Council of Sydney, Town Hall, Sydney, Aus.
MATTHEWS, CHARLES H., Electrical Engineer, M. A. Hanna and Co., 1300 Leader-News Bldg., Cleveland, Ohio.
PEEBLES, JOHN B., Professor of Engineering, Emory University, Emory University, Ga.
SURPRISE, EDWIN M. Equipment Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.
WATSON, WILLIAM G., Managing Director, W. G. Watson and Co., Ltd., 279 Clarence St., Sydney, Aus.
WINTERS, E. P., Chief Electrician, Woodward Iron Co., Woodward, Alabama.

TRANSFERRED TO GRADE OF FELLOW FEBRUARY 16, 1921

GRAY, GEORGE F., Assistant Manager, Engineering Dept., National Aniline & Chemical Co., New York, N. Y.
HAZELTINE, LOUIS A., Professor of Electrical Engineering, Stevens Institute of Technology, Hoboken, N. J.
OSBORNE, HAROLD S., Transmission Engineer, American Telephone & Telegraph Co., New York, N. Y.
WATERS, GRANVILLE A., Assistant Chief Engineer, Wagner Electric Mfg. Co., St. Louis, Mo.
WOODBRIDGE, J. LESTER, Chief Engineer, Electric Storage Battery Co., Philadelphia, Pa.

TRANSFERRED TO GRADE OF MEMBER FEBRUARY 16, 1921

APPLEYARD, ARTHUR E., Manager, Minneapolis Anoka & Cuyuna Range Ry. Co.; President, British Columbia & Alberta Power Co. Ltd.; Minneapolis, Minn.
BARNS, BIRD L., A. C. Engineer, Canadian General Electric Co., Peterborough, Ont.
BERNHARD, FRANK H., Editor, E. M. F. Electrical Year Book, Electrical Trade Publishing Co., Chicago, Ill.
CARPENTER, HENRY C., Chief Engineer, New York Telephone Co., New York, N. Y.
EVANS, PORTER H., Engineering Dept., Western Electric Co., New York, N. Y.
FECHT, ARTHUR J., Associate Electrical Engineer, Bureau of Standards, Washington, D. C.
GROSS, BENJAMIN, Chief Engineer, Hatzel & Buehler, Inc., New York, N. Y.
HANNAFORD, FOSTER, General Manager, Twin City Rapid Transit Co., Minneapolis, Minn.
HERRMANN, RAYMOND R., Instructor in Mathematics and Mechanics, University of Minnesota, Minneapolis, Minn.

LEE, CARL, Electrical Engineer, Peabody Coal Co., Chicago, Ill.
PETTY, EDWIN W., Electrical Engineer, H. M. Byllesby Co., Chicago, Ill.
POMEROY, WILLIAM D., Vice-President and General Manager, Goulds Manufacturing Co., Seneca Falls, N. Y.
POOL, RALPH Y., General Superintendent, Intermountain Railway Light & Power Co., Colorado Springs, Colo.
STICKNEY, H. RUSSELL, Electrical Engineer, Jackson & Moreland, Boston, Mass.
STOKES, STANLEY, General Supt. Outlying Plants, Union Electric Light & Power Co.; Vice-President & General Manager, Commercial Telephone Co., St. Louis, Mo.
WHALEN, JAMES M., Vice-President & Manager of Machine Dept., Northwestern Electric Equipment Co., St. Paul, Minn.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meetings held November 29, 1920, January 3, February 7 and 11, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To grade of Fellow

ACKER, ALBERT J., Electrical Engineer of Shaw Crane Works for Manning, Maxwell & Moore, Inc., Muskegon, Mich.
EWING, DRESSEL D., Professor of Electric Railway Engineering, Purdue University, Lafayette, Ind.
FINLAY, WALTER S., JR., Vice-President, American Water Works & Electric Co., New York, N. Y.
MACLACHLAN, WILLS, Electrical Engineer, Toronto, Ontario.
MOORE, EDWARD T., Electrical Engineer, Halcomb Steel Co., Syracuse, N. Y.

To grade of Member

ABBOTT, LEWIS W., Supervisor of Equipment, New England Tel. & Tel. Co., Boston, Mass.
BARNES, HAROLD B., Chief Engineer, Golden Fleece Mining & Milling Co., Denver, Colo.
BEAUCHAMP, LEON, Vice-President and Chief Engineer, The Solex Co. Ltd., Montreal, Quebec.
BRADLEY, HAROLD H., Commercial Engineer, Latin American Sales Dept., International General Electric Co., Schenectady, N. Y.
BROWN, GEORGE N., District Manager, Pittsburgh Transformer Co., New York, N. Y.
COOPER, CHARLES P., General Manager, Ohio Bell Telephone Co., Cleveland, Ohio.
DEFOREST, CORNELIUS W., Manager, Electrical Dept., Union Gas & Electric Co., Cincinnati, O.
FORGES, FREDERICK A., Consulting Engineer, New York, N. Y.
HOOD, JOHN, Local Engineer, General Electric Co., San Francisco, Cal.
JONES, PHILIP C., Electrical Engineer, Goodyear Tire & Rubber Co. of California, Los Angeles, Cal.
KEARNS, J. EDWARD, Electrical Engineer, General Electric Co., Chicago, Ill.
KELLEY, WILL G., Overhead Engineer, Commonwealth Edison Co., Chicago, Ill.
LEACOCK, GEORGE D. Y., Sales Manager, Moloney Electric Co. of Canada, Ltd., Toronto, Ont.
MEYERHERM, CHARLES F., Engineer, Albert F. Ganz, Inc., New York, N. Y.
MOLONEY, T. O., President Moloney Electric Co., St. Louis, Mo.
PATTERSON, JAMES G., Staff Engineer, New England Tel. & Tel. Co., Boston, Mass.
RICKWOOD, HAROLD A., Works Manager, Pirelli General Cable Works Ltd., Western Shore, Southampton, England.
SCHIRTZINGER, LEO, District Manager, Century Electric Co., Cincinnati, O.
SPEIGHT, HERBERT, Superintendent of Power, Granby Consolidated Mining, Smelting & Power Co. Ltd., Anyox, B. C.
WEBER, CORNELIUS, G., Assistant Engineer, Vaughn & Meyer, Milwaukee, Wis.
YOUNG, ROWLAND L., Power Engineer, Dept. of Development & Research, American Tel. & Tel. Co., New York, N. Y.
ZEHR, VRATISLAV A., Consulting, Designing, and Constructing Engineer, Pekin, Ill.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before March 31, 1921.

Abel, Lloyd C., Camden, Ark.
Adams, Calvin J., (Member), Syracuse, N. Y.
Adrianson, Gus W., Chicago, Ill.
Alexander, John P., New York, N. Y.

OFFICERS OF A. I. E. E. 1920-1921

President
A. W. Berresford

Junior Past-Presidents
Comfort A. Adams — Calvert Townley

Vice-Presidents
Charles S. Ruffner — C. E. Magnusson
Charles Robbins — E. H. Martindale
L. T. Robinson — C. S. McDowell

Managers
Walter A. Hall — Walter I. Slichter
William A. Del Mar — G. Faccioli
Wilfred Sykes — Frank D. Newbury
L. E. Imlay — Harold B. Smith
F. F. Fowle — James F. Lincoln
L. F. Morehouse — E. B. Craft

Treasurer
George A. Hamilton

Secretary
F. L. Hutchinson

A. I. E. E. COMMITTEES

(A complete list of the personnel of Institute committees will be found in the January issue of the Journal and will be published again in the June issue.)

GENERAL STANDING COMMITTEES AND CHAIRMEN

Executive, A. W. Berresford
Finance, Charles Robbins
Meetings and Papers, W. I. Slichter
Publication, N. A. Carle
Coordination of Institute Activities, L. T. Robinson
Board of Examiners, Clayton H. Sharp
Sections, John B. Fisken
Student Branches, C. Francis Harding
Membership, E. H. Martindale
Public Policy, H. W. Buck
Law, H. H. Barnes, Jr.
Headquarters, Wm. A. Del Mar
Safety Codes, Farley Osgood
Code of Principles of Professional Conduct, George F. Sever
U. S. National Committee of I. E. C., C. O. Mailloux
Standards, Dugald C. Jackson
Edison Medal, Comfort A. Adams
Research, F. B. Jewett

SPECIAL COMMITTEES AND CHAIRMEN

Geographical Divisions and Election Procedure, H. H. Barnes, Jr.
Superpower System, W. S. Murray

TECHNICAL COMMITTEES AND CHAIRMEN

Economics of Electric Service, Philip Torchio
Educational, C. E. Magnusson
Electrical Machinery, B. A. Behrend
Electrochemistry and Electrometallurgy, F. A J. FitzGerald
Electrophysics, F. W. Peek, Jr.
Industrial and Domestic Power, A. G. Pierce
Instruments and Measurements, F. V. Magalhaes
Iron and Steel Industry, W. F. James
Lighting and Illumination, C. E. Clewell
Marine, Arthur Parker
Mines, Graham Bright
Power Stations, H. P. Liversidge
Protective Devices, D. W. Roper
Telegraphy and Telephony, Donald McNicol
Traction and Transportation, Charles S. Ruffner
Transmission and Distribution, E. B. Meyer

A. I. E. E. REPRESENTATION

(The Institute is represented on the following bodies; the names of the representatives will be found in the January issue of the Journal and will be published again in the June issue.)

Council of the American Association for the Advancement of Science
American Bureau of Welding
American Committee on Electrolysis
American Engineering Standards Committee
American Engineering Council of the Federated American Engineering Societies
American Year Book Advisory Board
Board of Trustees, United Engineering Society
Engineering Foundation Board
Franco-American Engineering Committee
John Fritz Medal Board of Award
Joint Committee on Engineering Education
Joint Committee on Standard Thread for Insulators and Insulator Pins
Library Board of United Engineering Society
Electrical Committee of National Fire Protection Association
National Joint Committee on Overhead and Underground Line Construction
Engineering Division, National Research Council
Naval Consulting Board
Special Joint Committee on Determination of Power Factor in Polyphase Circuits
U. S. National Committee of the International Illumination Commission
Commission of Washington Award

A. I. E. E. SECTIONS AND BRANCHES

A complete list of the 39 Sections and 61 Branches of the Institute, with the names of the chairmen and secretaries, will be found in the January issue of the Journal and will be published again in the June issue.

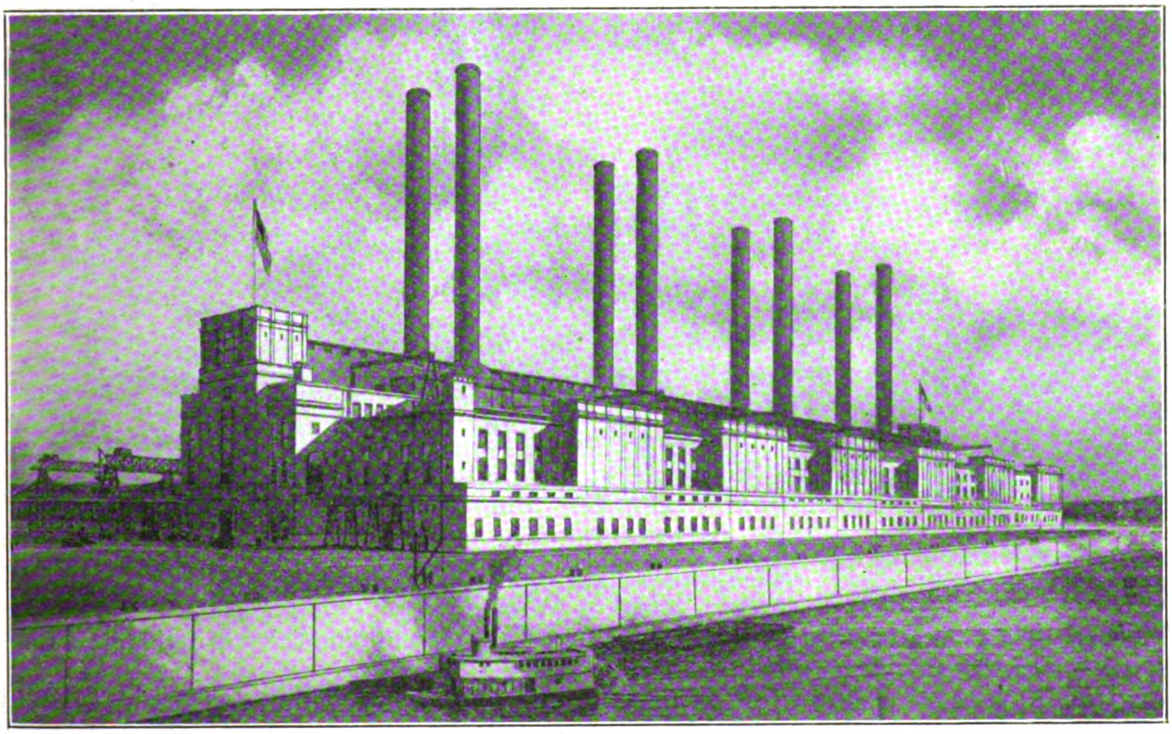
Colfax Power Station of the Duquesne Light Company Pittsburgh

By D. L. GALUSHA and C. W. E. CLARKE
of Dwight P. Robinson & Company, Inc.

THE PITTSBURGH district is the foremost steel-producing and manufacturing centre in this country. Steel plants with their furnaces and mills line the river banks for miles from the center of the city. Associated industries, attracted by an abundance of natural resources, adequate transportation facilities, ample labor supply, and proximity to markets for their products, have rapidly come into the adjacent territory. Growth during the war period was extensive, and the district as a whole has been busy since hostilities ended. Today, the Pittsburgh district may be fairly called the workshop of the world.



Colfax Power Station—The Ultimate Development

A power station which will utilize, for condensing purposes, the entire minimum flow of the Allegheny River in 300,000 kw. of turbo-generators housed in a building 830 feet long.

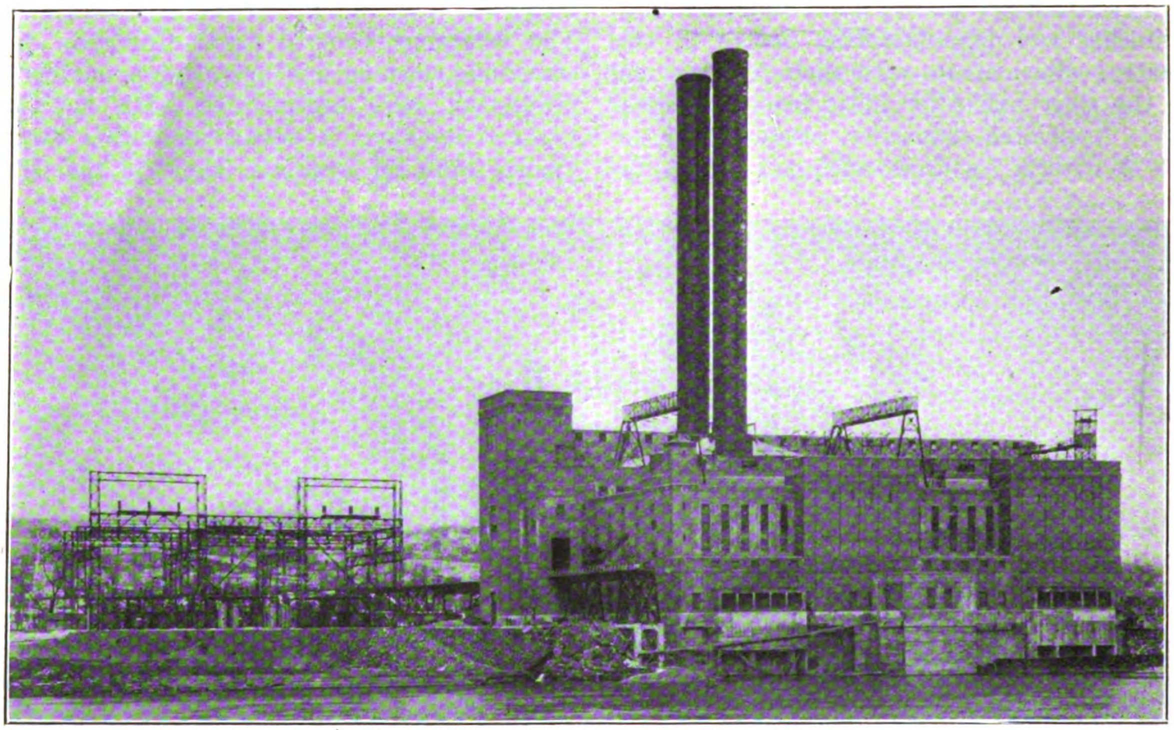
By 1912, central station facilities in the Pittsburgh district had become inadequate to meet the requirements of the rapidly growing industrial demand. The Allegheny County Light Company and other companies, owning and operating a number of small properties, were consolidated with the Duquesne Light Company. A steam-generating station previously built on Brunot's Island in the Ohio River below the city was considerably enlarged and the foundation laid for a comprehensive distribution system.

By an agreement with the West Penn Power Company and with the approval of the Pennsylvania Public Service Commission, a definite division of the territory served by the two companies was effected. The Duquesne Light Company, through this arrangement, serves the two counties—Allegheny and Beaver—with an area of 1154 square miles and a population of about one million and a quarter.

To be presented at the 369th Meeting of the A. I. E. E. in joint session with the A. I. & S. E. E., Pittsburgh, Pa., April 16, 1921.

In 1913, the first year after the formation of the new company, the energy output was 283,000,000 kw-hr. In recent years, the output has shown an average annual growth of about 15 per cent. Last year, the peak, which was somewhat affected by the curtailment of business, was 162,500 kw.; the energy output 805,000,000, kw-hr. giving a yearly load factor of 57 per cent.

Previous to 1921, power was generated at the Brunot's Island station of 120,000 kw. capacity and at six other plants, varying from 2000 to 17,000 kw. in rating. The total generating capacity safely available from all of these sources under maximum conditions is 160,000 kw.



COLFAX POWER STATION—THE FIRST STEP

A building for two 60,000-kw. units. The standard gage railroad entering the northwest corner of the building brings in the coal, and 66,000-volt cables descending from the roof to the steel structure at the west end of the building take the electric energy away.

In anticipation of the need of increased capacity, a site for a new power plant had been purchased. The location selected is on the Allegheny River about 15 miles from the center of Pittsburgh and only a mile distant from the Harwick mine. This mine and the private railroad from it to the power station are owned by interests affiliated with the Duquesne Light Company.

Actual construction of the new plant, known as the Colfax Power Station, was begun in September 1919, and the station was officially opened for service on December 18th, 1920. Transmission line and substation construction was in progress during the same period.

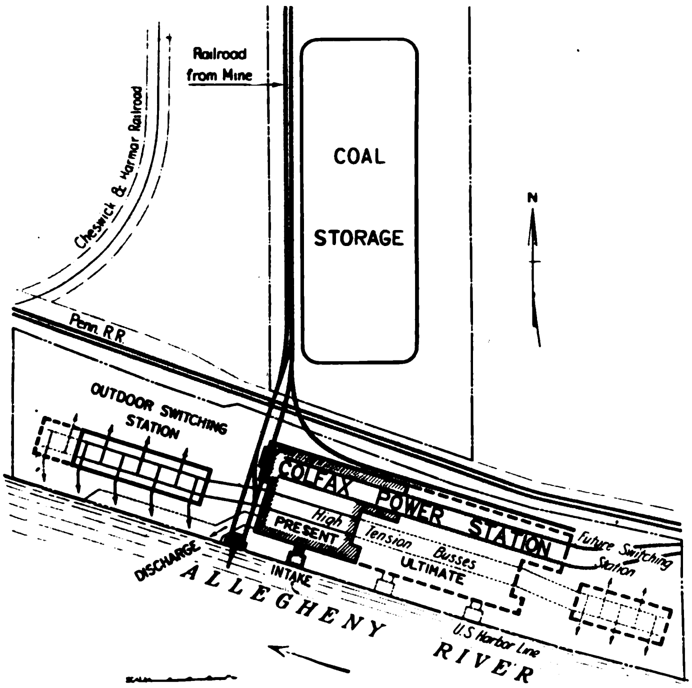
Duplicate 66,000-volt transmission circuits completely surround the city, forming an electric belt locally known as "The Duquesne Ring." The Brunot's Island and Colfax plants are almost diametrically opposite each other in this ring. Substations located at intermediate points and fed from either or both generating stations supply radial 22,000- and 11,000-volt feeders, which, in turn serve other substations and consumers within the industrial district.

In the design of the Colfax plant four major considerations have been kept in view; first, to plan for the largest development which is economical at the site chosen; second, to produce a plant which will generate power at the lowest unit cost, including fixed charges, permitted by the state of the art; third, to obtain the maximum reliability practicable, and fourth, to adopt simplicity of design as a fundamental policy.

The flow of the Allegheny River, upon which the plant depends for condensing water, is found to furnish a natural limitation to the capacity which may be developed at Colfax. The minimum flow of this river is sufficient to furnish condensing water for 300,000 kw., therefore the design is made so that the power station can be extended on a uniform plan until all available condensing water has been utilized. To allow for contingencies and spare equipment a development somewhat beyond the minimum is provided for.

The size of the unit chosen, 60,000 kw. nominal, is such that the ultimate development may be divided into five or six steps and when the plant is completed it will not be complicated with a large number of small units.

The first step of the development which is now completed includes one 60,000-kw. turbine and seven boilers. The power station building is, however, large enough for two units.



Power Station Lot Plan

This plan shows the relative locations of coal storage, power house and switching station. It also shows the simple and direct paths along which fuel, water and electric current progress on their way through the works.

The relative floor spaces occupied by the turbines and the boilers are important factors in the general arrangement of the power station. In this case the turbine room has a width of 84 ft. and the boiler room of 108 ft. which, together with the electrical bay, give a station 240 ft. wide over-all. The boiler room is 350 ft. long and the turbine room is 278 ft. long, giving an approximate balance in length between turbine and boiler room.

A Westinghouse three-cylinder compound turbine

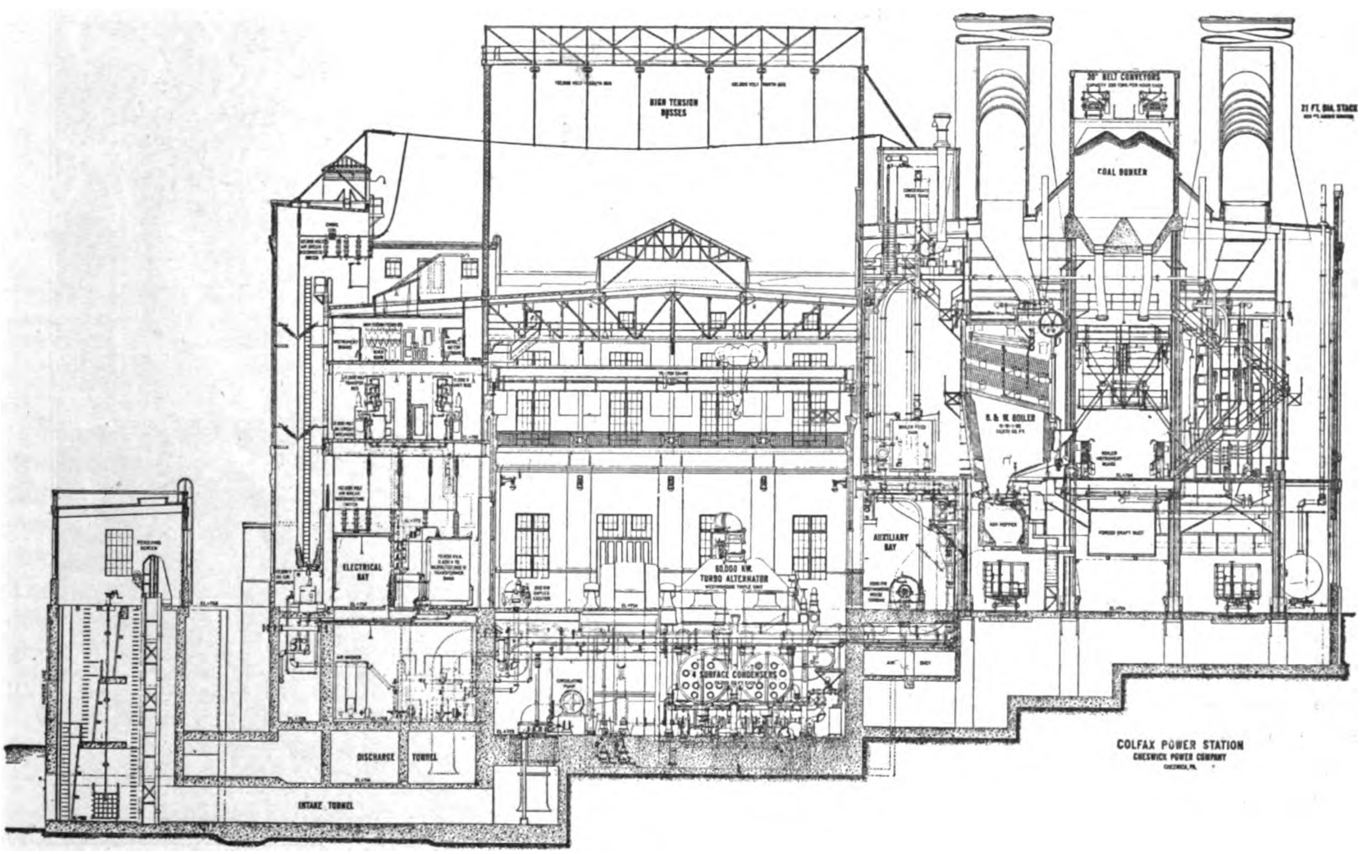
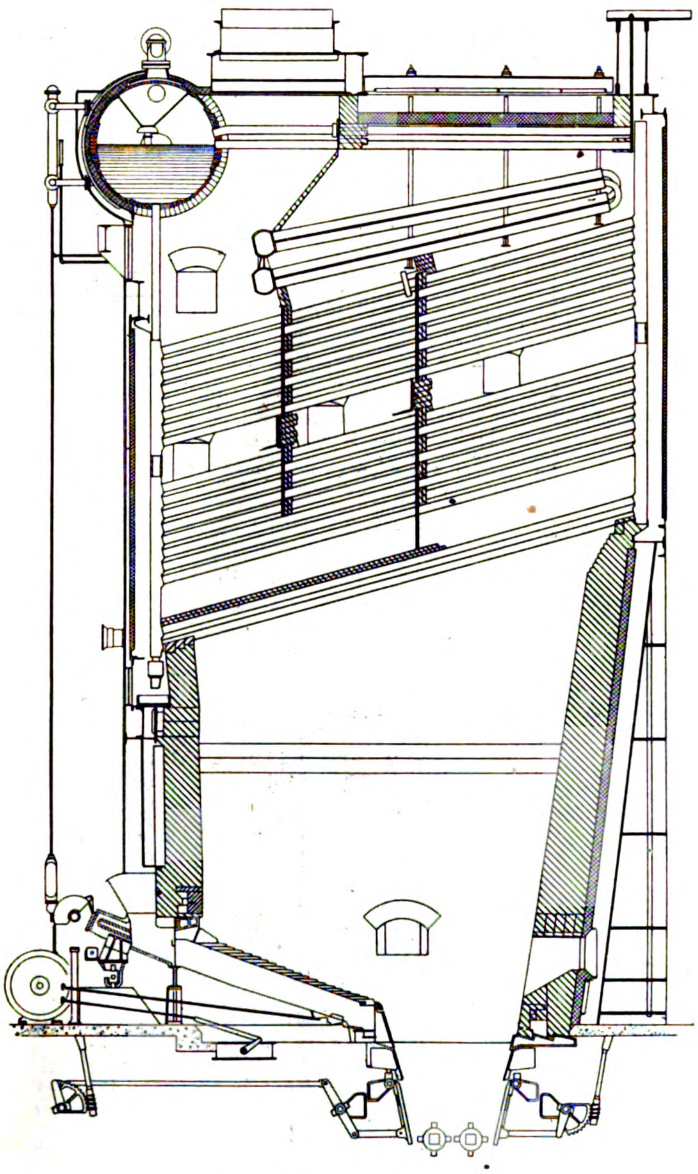
Relative location of boilers, stacks, draft fans, feed pumps, main turbines, house turbines, exciters, heat balance motor-generator, main transformers, house transformers and various auxiliaries.



Cross-Section of Colfax Power Plant

This section indicates the path of the coal from bunker through weighing larry to stoker and of ashes from stoker through ash hopper to railroad car. It also shows the path of the circulating water from intake through screen well, intake tunnel, circulating pumps and condensers to discharge tunnel. The arrangement of the apparatus in the electrical bay is well shown.

has been used. In this machine the expansion of the steam is divided into two steps and the low-pressure steam of the second step is divided into two parts. This division of the work of the steam gives three distinct mechanical elements, one being high-pressure and two low-pressure. These three elements are

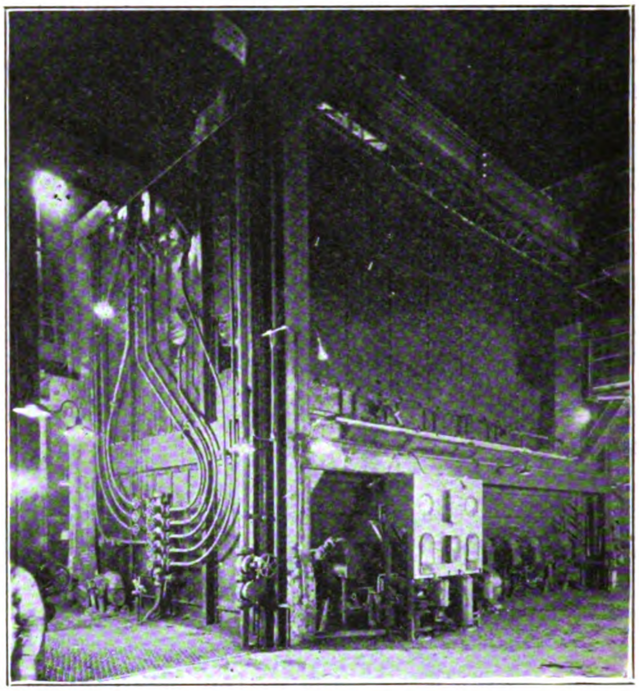


SECTION THROUGH BOILERS

The boilers are 18 tubes high with the two lower rows dropped below the tube bank and exposed to the direct heat of the furnace throughout their whole length. The boilers are set exceptionally high to give a large furnace volume.

logically grouped side by side with parallel shafts with the high-pressure element in the middle and one low-pressure element on each side. With this arrangement each unit occupies a space 50 ft. 10½ in. in the direction of the shafts and 79 ft. 2 in. at right angles to the shafts.

Babcock and Wilcox boilers of the greatest practicable width were selected, each boiler occupying a floor space about 34 ft. wide and 22 ft. from front to back.



COMPLETED BOILER

row of singly fired boilers, an arrangement which is highly desirable where the relative space occupied by turbines and boilers permits.

The illustrations herewith show the arrangement of the power house in much detail and the capacity and ratings of the important pieces of apparatus are listed in an appendix. A further detailed description is dispensed with in order to permit a discussion of some of the more important considerations which governed the design.

on an elevated trestle and the coal is dumped directly into the power station hoppers from which it passes by gravity to two crushers. The crushed coal is elevated by a bucket carrier to the top of the boiler room and is then distributed to the bunker by two belts with automatic traveling trippers.

The mine furnishes a semi-bituminous coal having a heating value of approximately 13,500 B. t. u. per lb. as received. Provision has been made for systematically testing the quality of the coal by taking a con-

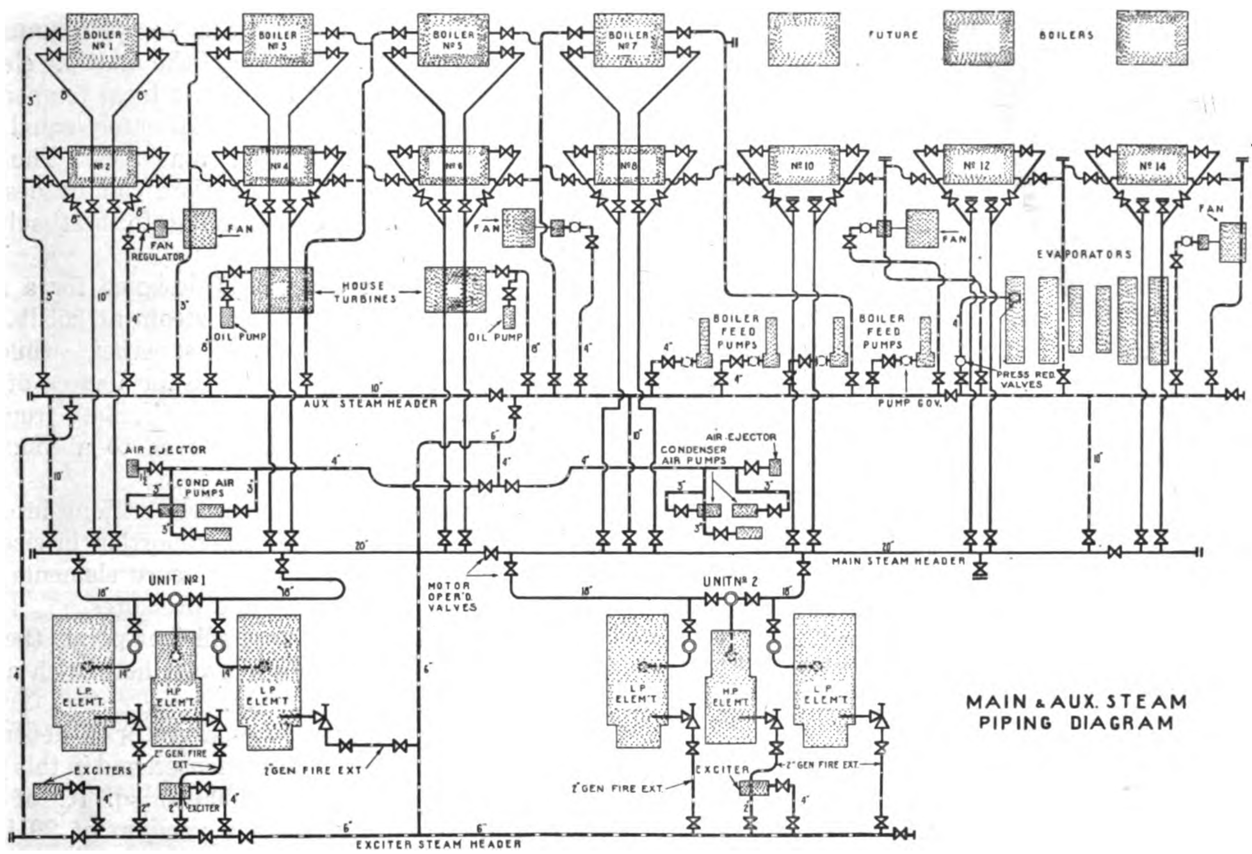

Diagram of Steam Piping

The high-pressure steam pipe which normally supplies only the high-pressure element branches to give an emergency supply to each low-pressure element. Each generator is piped to receive steam from the exciter steam header for use in extinguishing fire in the generator windings. This diagram covers the present unit and a future second unit.

Economy

An important factor in insuring the economical generation of power in this particular plant is its location near a coal mine. A mine mouth location, however, is not adapted to efficient generation unless combined with an ample supply of condensing water. The Colfax plant has therefore been located a short distance from the mine on the Allegheny River which gives a water supply of unusual magnitude for a mining region.

Great care has been taken that the coal should move forward in a simple manner from the mine to the furnaces with a minimum number of handlings and that it should be handled by gravity wherever possible.

A private railroad gives a cheap one-mile haul from the mine to the plant. At the plant the cars arrive

tinuous sample of the coal as it goes to the belts which distribute it to the bunker.

The quantity of coal used is determined by passing it through weighing larries with recording registers on its way from the bunker to the stokers.

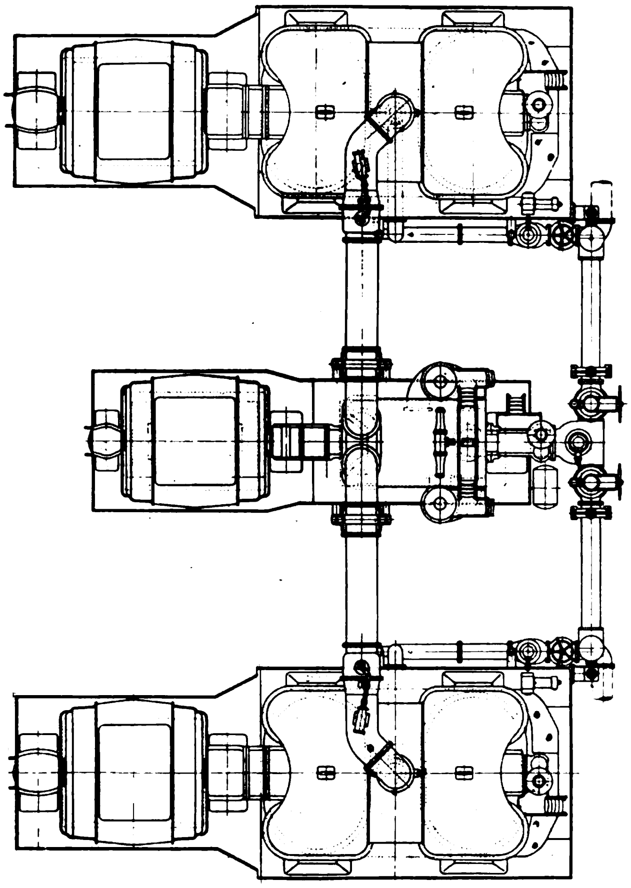
The ashes pass from the furnaces through clinker grinders to large hoppers for temporary storage. Air-operated ash gates discharge the ashes by gravity into standard railway cars in which they are removed without further handling.

From the furnace to the turbine every detail has been carefully considered so that the heat of the coal may be converted to electrical energy with the highest thermal efficiency.

The stokers are extra long and will burn coal at such a rate that the boilers will develop 300 per cent of rating

for peaks. However, so long as the load factor on the station is high a lower annual cost will be obtained by operating the boilers at from 200 per cent to 225 per cent of rating.

The boilers are set exceptionally high so that a furnace volume of approximately 3.45 cu. ft. per rated horse power is obtained. This liberal volume permits of the complete combustion of the coal even at high rates of evaporation in the boilers.



PLAN OF 60,000-KW. UNIT

The plan shows the three elements of one generator. Each element is of 20,000-kw. capacity. The speed of the central element is 1800 rev. per min. and the frequency 60 cycles; the speed of each outside element is 1200 rev. per min. and the frequency 60 cycles. The outer elements are spaced 30 feet on centers from the central element to give ample space around each element for convenient operation and also around the condensers in the basement below.

The boilers are 18 tubes high, which was the greatest height developed at the date of purchase. This gives the maximum amount of heating surface per foot of furnace width which is favorable for abstracting the greatest proportion of the heat from the gases on their way through.

The usual losses caused by air leaking through the brick boiler settings are much reduced in this plant by using steel casings.

A total steam temperature of about 600 deg. fahr. was chosen as giving the highest thermal efficiency consistent with thorough reliability. It was further decided that approximately 200 deg. fahr. of this steam temperature could best be used in the form of superheat. A gage pressure of 275 lb. per sq. in. was chosen in conformity with these considerations. To provide this superheat the superheating surface is 6700 sq. ft. as compared to 20,876 sq. ft. of heating surface in each boiler.

The instruments which are provided to permit of economical boiler operation include feed water regulators, water flow meters, draft gages, pyrometers and CO_2 recorders.

Excellent efficiency of the turbo-generators themselves is an essential element in insuring unusually high plant efficiency. The use of the multiple element type of machine has permitted the total temperature drop to be divided into two approximately equal steps which are utilized in separate machines. The high and low-pressure elements therefore can be designed with different speeds and blading to best suit the steam conditions.

The high-pressure element is designed for a speed of 1800 rev. per min. for taking steam at 265 lb. gage pressure and 175 deg. fahr. of superheat while the low-pressure elements are designed for a speed of 1200 rev. per min. for expanding the steam from an intermediate pressure of 55 lb. gage to a condenser pressure of one in. of mercury.

The division of the low-pressure machine into two elements removes an undue disproportion in size and speed between high- and low-pressure elements with this division of temperature and pressures.

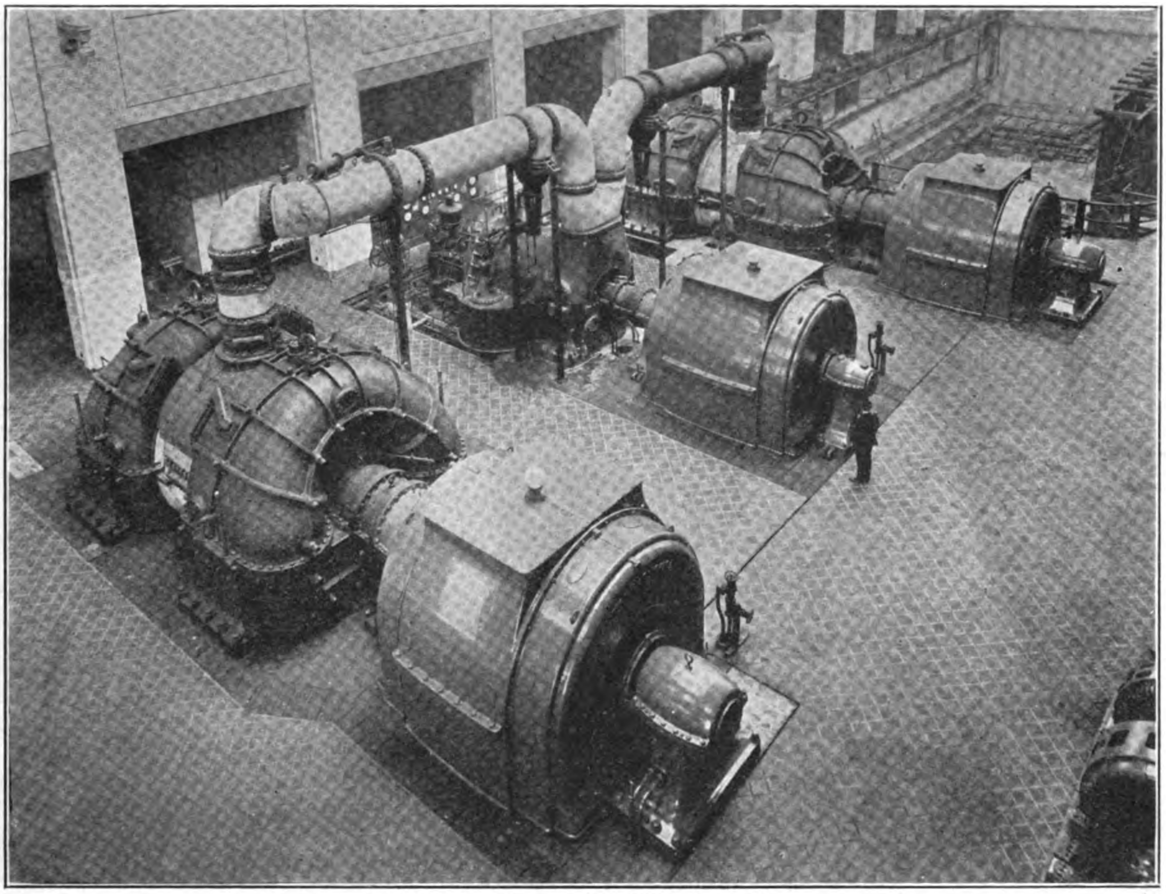
When operating at its most efficient point, the unit is guaranteed to generate a kilowatt hour with a consumption of steam of 10.58 lb.

The efficiency of the turbo-generator is dependent in a large measure on the condenser, and in this plant each unit is provided with 100,000 sq. ft. of condenser surface which insures a vacuum of 29 in. at full load.

While a plant should have a high thermodynamic efficiency if each of the major elements, furnace, boilers, turbines and condensers is highly efficient, there is an opportunity for material losses to occur in the numerous auxiliaries, which, with the best of design, may consume 12 per cent as much steam as the main turbines. In this plant great care has been taken in the design of each auxiliary system to stop all preventable losses.

The feed-water system may be taken for example as the most important of the auxiliary systems.

Under normal full-load conditions approximately 87 per cent of the water evaporated in the boilers is used in the main turbines, is condensed in their condensers and, then reused for boiler feed water. Another 10 per cent is used in operating auxiliaries and may also be condensed and used for boiler feed water. The remaining 3 per cent is accounted for in steam used in soot blowers, boiler blow-downs, drips, drains, vents and so forth where the water cannot be recovered.

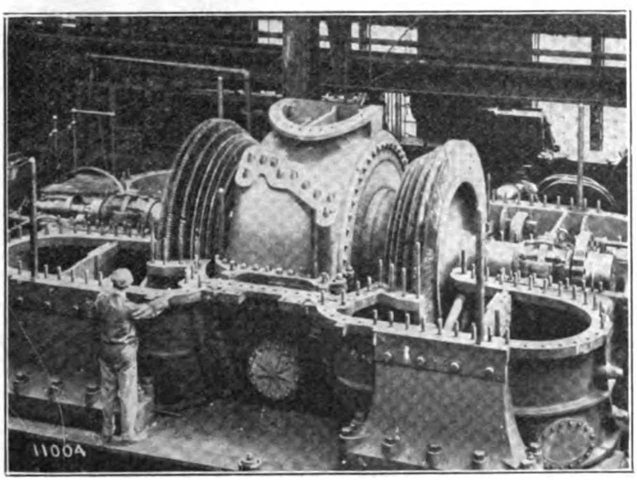


GENERAL VIEW OF 60,000-KW. UNIT

The central or high-pressure element receives steam from the boilers at 265-lb. pressure and exhausts it into the branched overhead pipe through which it passes at about 55 lb. to the two outside low-pressure elements. A butterfly valve in each branch of this pipe permits of this steam passage being closed.

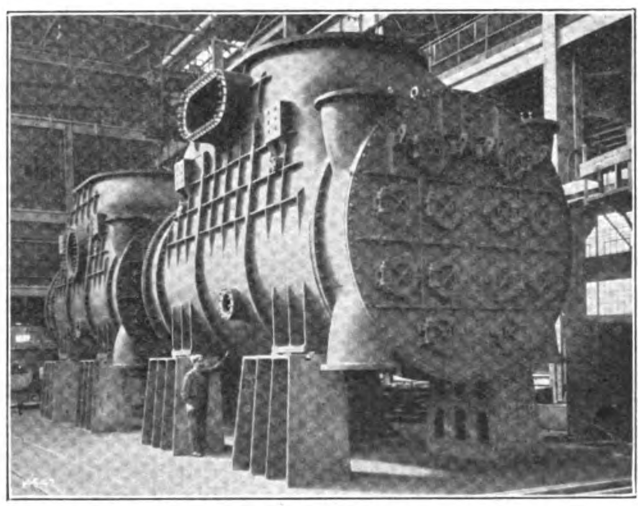
This loss of water is made up by evaporating river or well water to purify it before allowing it to enter the boilers.

The condensate from the main turbines which is the principal source of feed water is removed from the condensers by the hot well pumps at a temperature



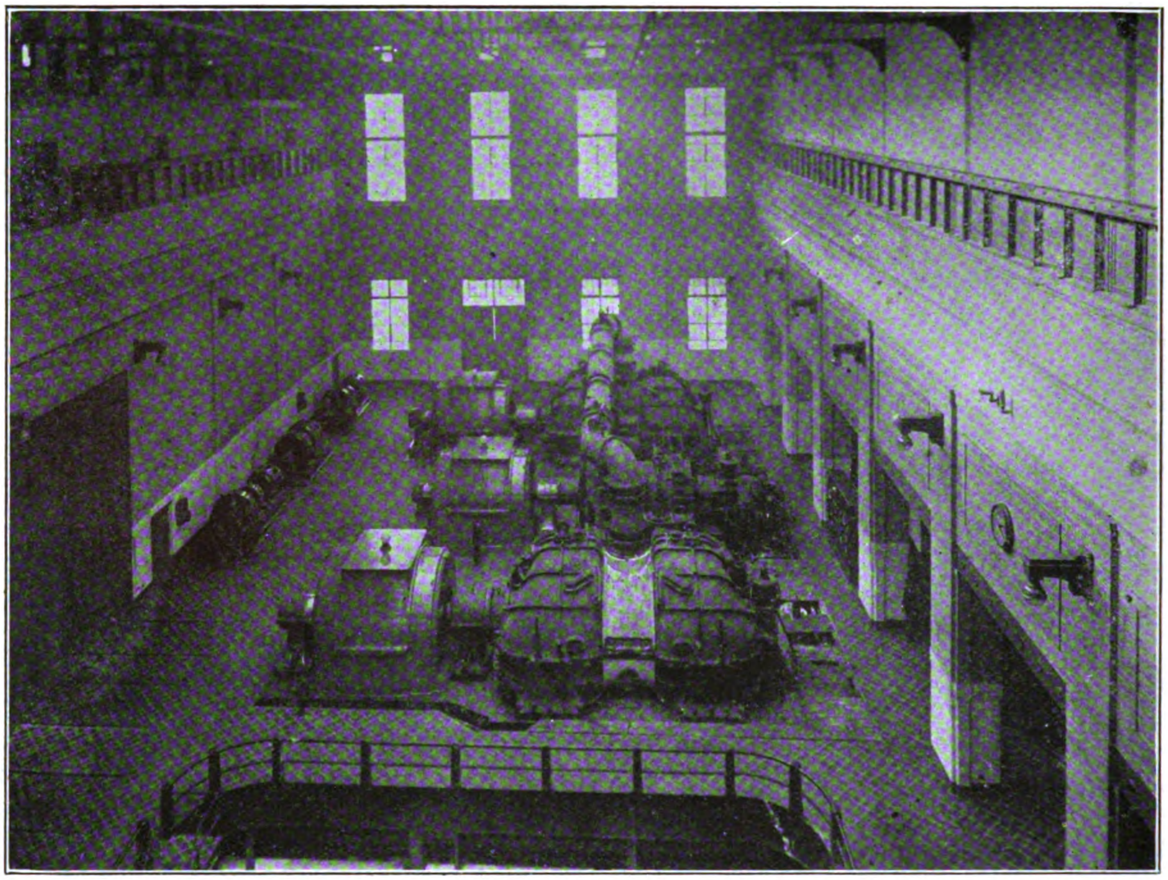
A LOW-PRESSURE ELEMENT

This 20,000-kw. 1200 rev. per min. turbine is of the semi-double flow construction. The steam entering through the opening shown at the top first passes through a section of single flow blading concealed beneath the central casing which is shown in place. The steam then divides and flows toward each end through the double flow blading which is exposed in the view by the removal of the outer casing. At each end the exhaust steam is discharged from the turbine through a separate opening below the floor. These two openings connect with separate condenser shells.



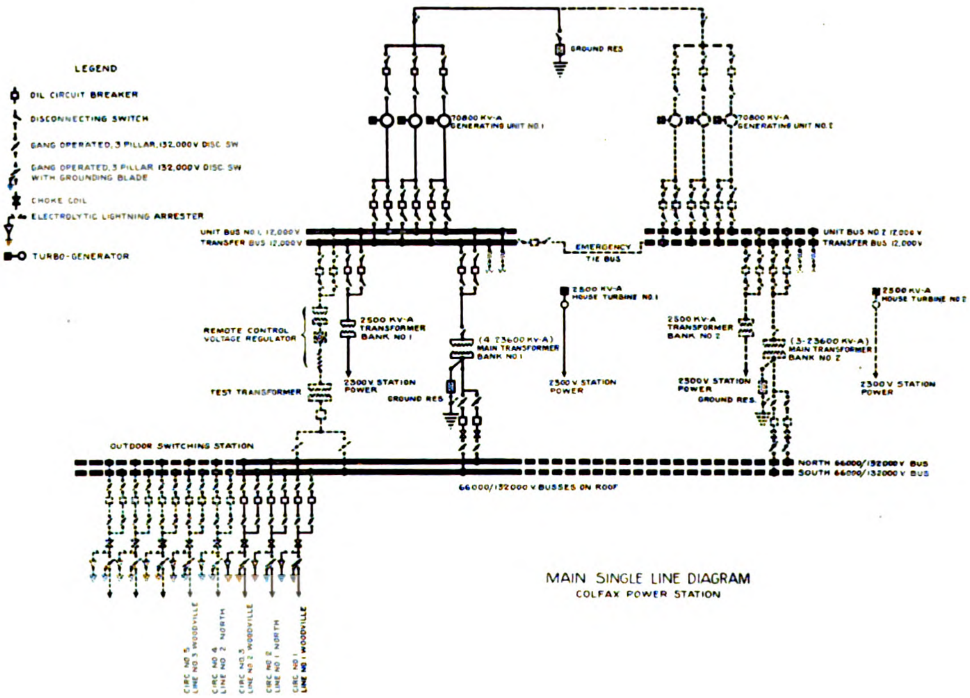
CONDENSER

Each unit has 100,000 sq. ft. of condenser surface divided between four shells. This view taken in the shop shows two shells, that is, one-half of the condenser for one unit. Exhaust steam enters the top of each shell through an elliptical opening 14 feet long and 9 feet wide. The smaller elliptical side outlet is for an equalizing pipe between the two shells of the same element. The divided water box construction which permits of separate cleaning of the halves of each shell is indicated by the duplicate flange on each side for circulating piping. The shell is shown standing on feet which are provided for convenience in erection. When in service it is suspended from a steel framework by straps which attach to the pads just below the equalizing opening.



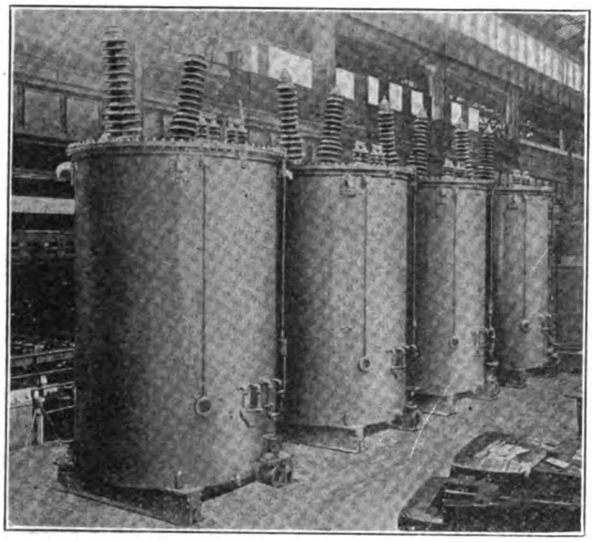
General View of Turbine Room

The units are spaced 125 feet on centers with a pit between for dismantling generators and transformers. The auxiliary bay which opens into the turbine room contains the feed pumps, draft fans and house turbines, thus bringing all steam driven auxiliaries to the turbine room floor and under the care of the turbine room operators.



Main Electrical Connections

The main circuit consists simply of a lead from each element to an isolated 12,000-volt bus which unites the three currents into one, a lead from this bus to a transformer bank which steps the voltage up to 66,000 volts, a lead from the transformer bank to a high-tension bus which carries the current from the power house to a switching station where it divides among three outgoing feeders. To facilitate maintenance and repairs both the low-tension and the high-tension busses are in duplicate with oil selector switches throughout.

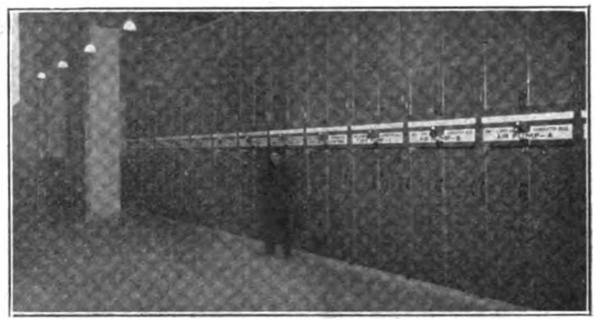


THE FOUR 23,600-KV-A. TRANSFORMERS

These are the largest single-phase transformers that have ever been constructed. Each is approximately 10 feet in diameter and 22 feet high over the terminals. Three of these units form one transformer bank and the fourth is a spare. The low-tension windings are connected delta for 12,000 volts and the high-tension windings are connected star for either 66,000 or 132,000 volts.

of 75 deg. fahr. It is desirable to raise the temperature of this water to about 200 deg. fahr. and to add to it the water used by the auxiliaries and the make-up water from the evaporator before pumping it into the boilers. It is furthermore desirable that all heat transferred in the process should be most efficiently utilized.

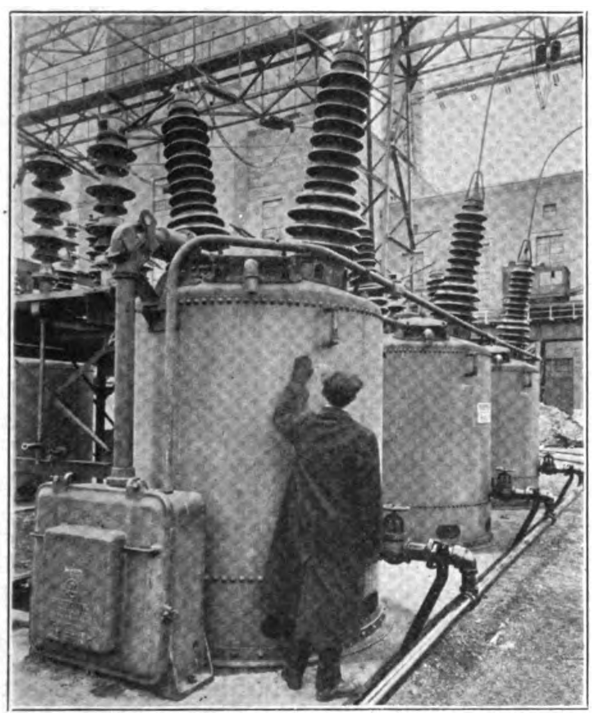
In this plant the process is therefore divided into several steps.



2300-VOLT BUS STRUCTURE

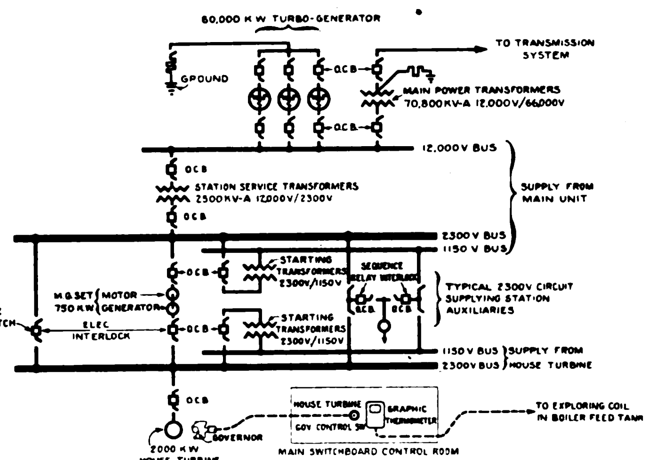
The 2300-volt circuits are used exclusively for supplying station auxiliaries. The 2300 system is supplied from duplicate sources, a separate 2000-kw. house turbine and a 2500-kw. bank of station transformers. As absolute dependence has been placed on electric drive for a majority of the essential auxiliaries the 2300-volt busses have been carefully safeguarded in cell work.

1. The auxiliary live steam is used to produce as much mechanical power as possible before its heat is used for other purposes. The auxiliaries which are steam-driven are the feed pumps, the forced draft fans and the house turbo-generator. The amount of exhaust steam from the feed pumps and draft fans is always less than the minimum necessary and the additional steam from the house turbine may be controlled at will by transferring load electrically between the generators of the house turbine and the main turbine.



A 132,000-VOLT, 400-AMPERE CIRCUIT BREAKER

The three tanks shown form a single three-pole oil circuit breaker. There are two of these breakers in the power station to control the high-tension circuit from the transformer bank and six in the outdoor switching station to control the three outgoing lines. Each switch is electrically operated by mechanism enclosed in the iron box shown at the end of the row of tanks. The electrical operation is by remote control from the switchboard.



CIRCUIT DIAGRAM AUXILIARIES & HEAT BALANCE CONTROL

DIAGRAM OF AUXILIARY CIRCUITS

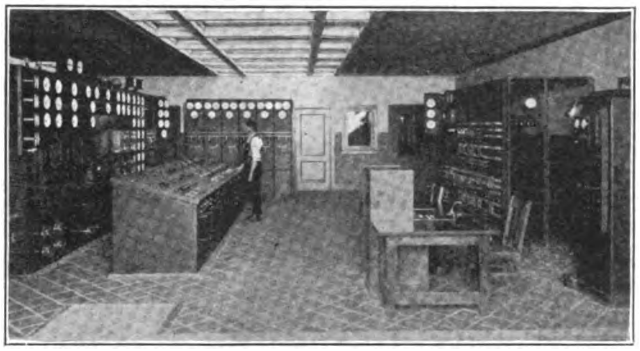
The essential auxiliary connections showing method of heat balance control from switchboard room.

2. Part of the exhaust steam from the auxiliaries is first used in the evaporator for evaporating make-up water.

3. The heat used in the evaporator is again recovered

and adds some 20 deg. to 30 deg. to the temperature of the main condensate which passes as circulating water through the condenser of the evaporator to condense the make-up water.

4. The steam from the auxiliaries, which is not needed in the evaporator, is condensed in a barometric condenser, which uses as condensing water the condensate from the main condensers that has already been raised in temperature 20 deg. or 30 deg. as above mentioned.



CONTROL ROOM

This shows the room 48 ft. long by 30 ft. wide from which the plant is controlled.

This combination is designed to maintain the feed water at a normal temperature of about 200 deg. fahr. without waste of either water or heat.

The electrical method of transferring the load between the house turbine and main turbine is particularly interesting. Practically all the station auxiliaries are electrically operated by induction motors which are normally supplied from the house turbine circuit. The house turbine circuit has, however, a second source of supply from a generator driven by an induction motor receiving its supply from the main generators. When the house turbine is run at the same frequency as the main generators the motor-generator will furnish no power and the house turbine will carry all of the electrical station auxiliaries alone. The speed of the house turbine is adjustable by the usual governor control, and as its speed is reduced the motor-generator will pick up load on the house circuit. The whole load or any part of it may be transferred from the house generator to the main generator.

The electrical losses inside of generating stations are so small that large savings are not possible, but in this plant there has been some improvement in transformer efficiencies. These transformers which are larger than any other single-phase units yet constructed have the high full-load efficiency of 99 per cent.

Records are not yet available to show the normal performance of the plant in actual service, but calculated figures indicate that at a load of 50,000 kilowatts, its coal consumption should be about 1.39 lb. per kw-hr.

RELIABILITY

Reliability without sacrifice of economy has been the next major consideration in the plant design.

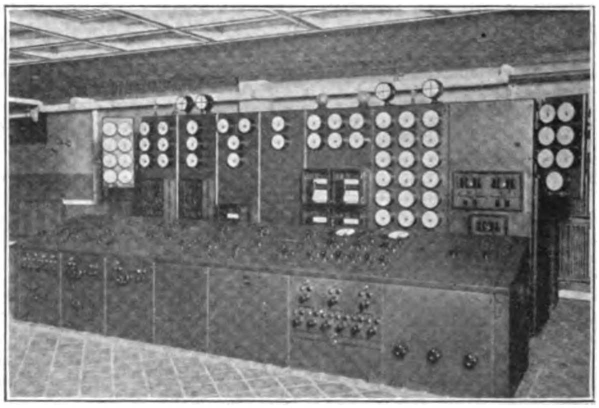
The coal supply is the first point requiring safe-guarding. The natural coal supply of the Colfax plant is direct from the Harwick mine. Two alternative methods of supply are however provided, either by barge on the river or by car over the Pennsylvania Railroad. Finally a coal storage of 150,000 tons within a few feet of the power station makes interruption of fuel supply a remote contingency.

Inside the power house the coal hoppers, coal crushers, coal elevators and conveyors are all in duplicate and each half has a capacity of 200 tons per hour. Furthermore, the coal bunker provides a storage of 240 tons immediately over each boiler.

The number and capacity of the boilers is such that it is always possible to take a boiler out of service when it is desirable for cleaning or proper maintenance.

The furnaces are designed to permit high furnace temperature with a minimum of brickwork upkeep.

In the high-pressure steam piping, special care has been used to insure reliability. Thus in the flanged joints double threaded bolts with two nuts of special high-grade, oil-treated steel are used. This avoids upsetting the material to form a head and results in a more reliable bolt.



MAIN BENCH BOARD

This is the board from which all the main circuits are controlled. On top of the desk apron there are mimic busbars representing the actual circuits in diagrammatic form. Circuits of different potential are distinguished by the use of different finishes for these busbars.

The division of the main unit into three mechanically distinct elements minimizes the loss of capacity from an accident to the machine, as any two of the elements may be operated with the other out of service or any one may be operated with the other two out.

Normally, all the steam supplied to the unit is under the control of the governor on the high-pressure element, but each low-pressure element is also equipped with a governor.

The closing of a butterfly valve in one branch of the steam pipe between the high and low-pressure cylinders

cuts off the low-pressure steam supply to that low-pressure element. Then the opening of a direct steam connection to the boilers permits of that low-pressure element being operated as an independent condensing turbine on its own governor. Either or both of the low-pressure elements may be so operated.

With the butterfly valves closed in both branches of the pipe between the high and low-pressure cylinders and with the atmospheric relief valve open, the high-pressure element may be operated as an independent non-condensing turbine.

The opening and closing of the proper valves for shifting to separate operation in case of an emergency is automatically controlled by the governors.

Overspeeding of a low-pressure element closes the butterfly valve and cuts off its low-pressure steam supply while a drop in speed admits live steam from the boilers.

Overspeeding of the unit cuts off all steam from the unit and closes both butterfly valves, but a subsequent slowing down will admit live steam to the low-pressure elements.

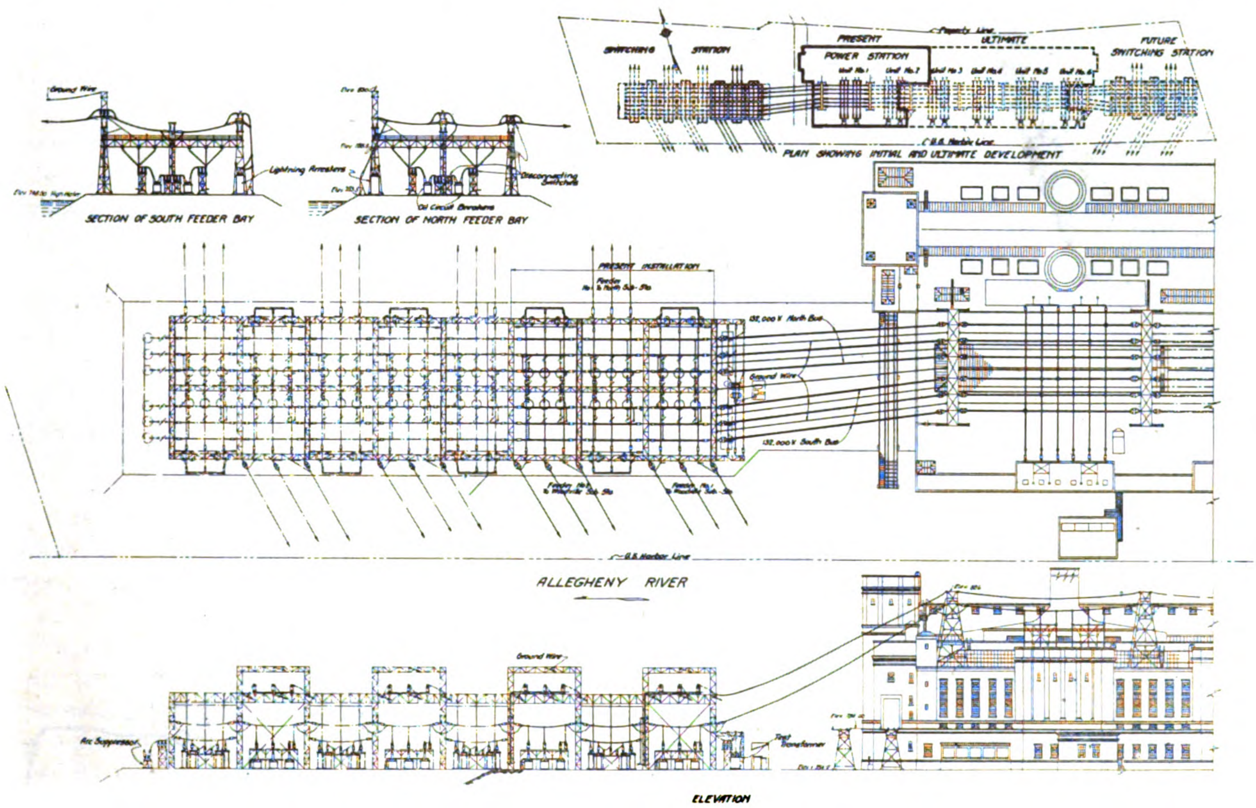
Each of the low-pressure elements is of the semi-double flow type with two exhausts from each cylinder. This has naturally resulted in dividing the condenser surface between four shells. Each shell is so divided that one-half of it may be isolated for cleaning, permitting one-eighth of the total surface to be cleaned at a time without interruption to service.

The excitation system is especially well protected against interruptions. The exciters are in duplicate, one being a spare machine. The exciters are normally motor-driven, but each is also connected to a steam turbine. When the exciter is being driven by the motor, a small amount of live steam is admitted to the turbine casing and if the motor permits the speed to fall, the turbine automatically takes the load from the motor and maintains the excitation.

The electrical devices provided for protecting the generator include a differential relay operated by the difference between the line and neutral current which will automatically perform all the functions necessary for isolating that generating element in case of an internal short circuit; a resistor of seven ohms between the generator neutrals and ground which limits the current to ground on the 12,000-volt system to 1000 amperes; and six resistance coils and six thermocouples for temperature measurement.

Great care has been used in insulating the connections from the generators to the busses. These consist of cables insulated for 13,000 volts, mounted on porcelain insulators as an additional precaution.

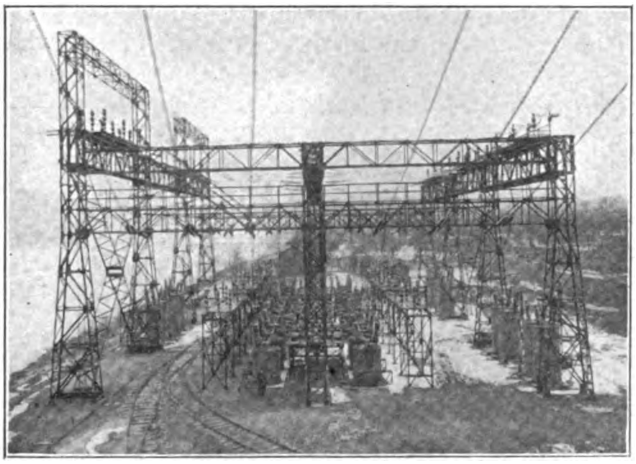
Four single-phase step-up transformers are installed, of which one is a spare unit. The spare transformer has all piping connections in place and is provided with disconnecting switches on the low-voltage side and removable pipe links on the high-voltage side, by means of which it can be connected



OUTDOOR SWITCHING STATION

The high-tension busses extend in a continuous line the length of the turbine room roof, thence across an intervening space to the switching station and then the length of the switching station. The switching station is divided at right angles to the busses into bays, each bay being used to control a separate line.

in place of any of the others in a few minutes. Each transformer has two hot-spot temperature indicators, one at the switchboard and one at the transformer, designed to show the highest temperature existing at the hottest spot in the transformer coils. The transformers are protected by differential relays in case of internal short circuits and by heavily set overload relays in case of a short circuit on the high-tension busses. The neutral of the high-voltage windings of



OUTDOOR SWITCHING STATION

The station consists of an iron framework supporting the insulators, horn gaps, conductors and disconnecting switches which are required. Oil circuit breakers and lightning arresters which stand on the ground.

the transformer bank is connected to ground through a resistance, which will limit the current in case of a ground on the high-tension circuit.

All electrical auxiliaries have duplicate sources of supply and may be operated from either the main generators or the house turbine.

The motor-generator which normally interconnects the main and the house turbine has reverse power relays which will disconnect it in case the frequency of the main turbine falls to a point where it would materially interfere with the operation of the house turbine or station auxiliaries.

In order that disconnecting switches may be opened and closed only when the corresponding oil switch is open, each set of switches is provided with a protective device, including as the indicating element, three lamps. A red light indicates a closed circuit breaker, a green light that the breaker is open and a white light that the control wires to the breaker are open.

Electric control is used for so many operations that a dependable supply is essential. Duplicate batteries, charging sets and busses are provided. Each circuit is equipped with a double throw switch for connecting to either bus.

A complete emergency lighting system provides sufficient light at every important point to permit of the operation of the station without hazard. When the normal alternating-current supply of the emergency lighting circuits is interrupted, connection is automatically made to a storage battery.

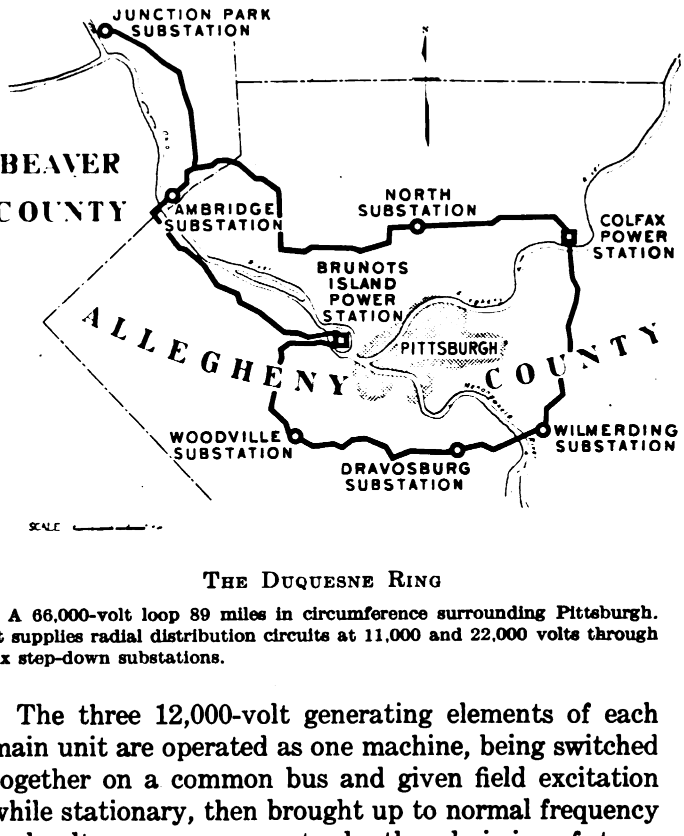
The various precautions to insure reliability above described may be summarized as including, first, careful design and a high factor of safety to prevent accidents, second, a complete duplication of all important but inexpensive elements so that complete service may be maintained in spite of any failure, and third, a subdivision of the large and expensive elements so that a failure merely causes a diminution of capacity without an interruption to service.

SIMPLICITY

Simplicity of design has been favored by the large size of the units, but great care has been necessary to attain reliability while preserving the simplicity.

The low steam consumption of the turbine and the large capacity of the individual boilers have simplified the boiler room by permitting a single firing aisle.

Each turbo-generator is regarded as a single unit taking steam through a single governor and delivering high-tension current through a single transformer bank. The division of the unit into three mechanical elements and the resulting division of the generated current into three low-tension circuits are regarded as internal structural peculiarities which can be taken advantage of in case of an emergency but which should not be made an excuse for complicating the design.



THE DUQUESNE RING

A 66,000-volt loop 89 miles in circumference surrounding Pittsburgh. It supplies radial distribution circuits at 11,000 and 22,000 volts through six step-down substations.

The three 12,000-volt generating elements of each main unit are operated as one machine, being switched together on a common bus and given field excitation while stationary, then brought up to normal frequency and voltage as one generator by the admission of steam to the high-pressure turbine and synchronized with the 66,000-volt system through the low-tension circuit breakers of the 70,000-kv-a. transformer bank.

When other units are added each is to have its own isolated 12,000-volt bus. Each generating unit may be considered as a single 66,000-volt machine. The station bus on which the machines operate in multiple is the high-tension bus from which the transmission circuits are supplied. This simple plan has been developed by taking advantage of the location of Colfax at a point where the local loads are not heavy and recognizing that there would be an undue expense and complication if a common low-tension bus were established in order to supply a small local load.

The use of a single transformer bank for each three-element unit simplifies the transformer house while the use of single-phase transformers provides a subdivision of the capacity which gives added reliability without complication or expense.

Another simplification in the power house is obtained by separating the distribution of power from its generation. With this plan the only switches in the power house are those of the generators and auxiliaries. The only high-tension switches which must be provided for in the power house design are two selector switches for each generator. After passing through these switches the generator circuits go out doors to the duplicate station busses which are suspended above the roof. The current thus leaves the power station proper at one end over two busses.

The distribution of power from a separate point permits the use of a simpler design and less expensive construction for this purpose than would be necessary in the power station building.

These simplifications in design have been important factors in keeping down the cost of the station. In spite of the fact that the station was constructed just at the time when the prices of material and labor were at their maximum the cost of that part of the plant which should be allocated to the first unit was about $105 per kilowatt.

APPENDIX

CAPACITY AND RATING OF APPARATUS

Coal Handling Apparatus. Duplicate concrete receiving track hoppers, each 150 tons capacity.

Duplicate crushers, each 200 tons per hour capacity.

Duplicate bucket elevators with overlapping, pivoted buckets, each 200 tons per hour capacity.

Duplicate 30-in. belt conveyers, each 200 tons per hour capacity.

Reinforced concrete bunker, capacity 10 tons, per lin. ft., or 240 tons per boiler.

Duplicate weighing larries, each 20 tons capacity.

Stokers. 17-retort, extra long underfeed with double roll clinker grinders.

Ash Handling Apparatus. Ash hoppers of reinforced concrete, brick-lined, 1900-cu. ft. capacity per boiler, fitted with air-operated ash gates, discharging direct into standard gage railroad cars.

Boilers. Seven Babcock & Wilcox steel-cased cross-drum boilers. Each contains 20,876 sq. ft. of heating surface, is 51 tubes wide and 18 tubes high. Tubes 20 ft. long; diameter of cross-drum 60 in.; steam pressure 275 lb.; furnace volume 3.45 cu. ft. per rated h. p.

Superheaters: Foster type, located above tubes between first and second pass. Each contains 6700 sq. ft. of heating surface giving from 140 deg. to 200 deg. superheat.

Forced Draft System. Three 250,000-cu. ft. per min. fans driven by 420-h. p. geared steam turbines. Air supply taken from generator discharge and boiler room basement.

Stacks. Two brick lined self-supporting steel stacks, each 21-ft. diameter with top 325 ft. above firing floor. Flues are above roof and covered with magnesia with sheet metal protection.

Main Turbo-Generator. One Westinghouse 60,000-kw. three-cylinder, two-stage parallel flow, compound steam turbine generator unit consisting of one 1800-rev. per min., single-flow high pressure element, and two 1200-rev. per min. semi-double-flow low-pressure elements; each element driving one 23,600-kv-a., 85 per cent power factor, 60-cycle, 12,000-volt, three-phase generator. Generators are star-connected with three neutral connections brought out; seven-ohm external resistance in ground circuit.

Main Unit Auxiliaries. Condensing equipment has 100,000 sq. ft. of surface in 4 two-pass shells of 25,000 sq. ft. each, connected to turbines by means of rubber expansion joints. Each condenser shell contains 5070 one-in. Muntz metal No. 16 gage tubes of 18 ft.-10 in. active length.

Three circulating pumps, each 44,000 gal. per min., motor-driven.

Four condensate pumps, each 1000 gal. per min., two-stage, motor-driven.

Three Leblanc air pumps, each 30 cu. ft. per min., motor-driven.

Two submerged removal pumps, each 900 gal. per min., motor-driven.

Two air washers, each 115,000 cu. ft. per min.

Station Auxiliaries. "House" turbo-generator: One 2000 kw. 2300-volt, three-phase, 60-cycle unit, the turbine operating at boiler pressure and exhausting into barometric condenser.

Heat balance set: One 1100-h. p. 2300-volt, three-phase 60-cycle motor driving 750-kw., three-phase, 60-cycle, 900-rev. per min. 2300-volt synchronous generator. This set connected between the house turbine bus and the auxiliary bus fed from main turbo-generator.

Duplex exciters: Two sets, each consisting of a steam turbine on common shaft with 350-kw. 250-volt, d-c. generator and 530-h. p. 2300-volt motor.

Motor-generator sets for stoker and clinker grinder supply: Two, each consisting of 325-h. p. three-phase, 60-cycle, 2300-volt motor driving 200-kw. 250-volt, d.c. generator.

Battery charging sets: Two, each consisting of 25-h. p. three-phase, 60-cycle, 440-volt motor driving 15-kw. 125-volt, d-c. generator.

Elevator: Combination passenger and freight, automatic, two-ton capacity; to all floors on electrical bay side.

Evaporator, double effect, "dry-tube" type: Capacity 15 tons per hour. The two effects reversible.

Three boiler feed pumps: Each 1500 gal. per min. four-stage centrifugal, turbine-driven.

Main distilled water storage tank: Capacity 200,000 gallons.

Traveling crane: One four-motor, 75-ton main hoist, 25-ton auxiliary hoist.

Transformers. Main Transformers: Four 23,600-kv-a. 11,500/38,100/76,200-volt single-phase, 60-cycle, oil-insulated, water-cooled, low-tension delta, high-tension star. One transformer in reserve as spare.

Station Transformers: Three 833-1/3-kv-a. 11,500/2,300-volt single-phase, 60-cycle, oil-insulated, water-cooled, connected delta-delta.

Duplicate Storage Batteries. For circuit breaker control and emergency lighting. Each 125-volt, 160-ampere-hour.

Main Switchboard. Desk type for controls, vertical panels in rear for instruments on main board of seven sections. All other boards of vertical type. Panels of slate. Mimic busses of all circuits with different finish for each voltage.

Circuit Breakers. Remote control, solenoid-operated, type O-2 and CO-2 on 12,000-volt circuits; type G-2 on high-tension circuits.

Emergency Lighting. Emergency lights throughout plant automatically transferred from normal supply to storage batteries in case of station trouble; restored when trouble is removed.

Telephone, Etc. Duplicate private branch exchange boards. Telephones installed in all parts of building and important points outside of station. Loud speaker on main instrument board permits operator to talk without head set.

Master clock in control room with auxiliary clocks in various parts of building.

Load indicator in center of boiler room firing aisle with double-faced illuminated dial electric clock and steam gage.

Signal System. Induction regulator type sending and reeiving indicators and transmitters between control room and gage boards.

The Frequency Problem in the Steel Industry

BY B. G. LAMME

Chief Engineer, Westinghouse Elec. & Mfg. Co.

The standard frequency of 25 cycles for steel mill plants was adopted many years ago, when the conditions were such that this frequency more nearly met the steel mill requirements than was possible with 60 cycles. With the coming of large central power stations, for the general supply of electric service of all kinds, the frequency of 60 cycles has come into more general use. In consequence, in considering the purchase of power from the large supply companies, the steel mills are now confronted with the problem of utilizing 60 cycles to best advantage in plants which were initially designed for 25 cycles.

Various possibilities for utilization of 60 cycles in such plants are given, and the advantages and disadvantages of each are discussed briefly.

The intent of the paper is to bring forward certain points for free discussion, rather than to attempt to solve the problem, it being recognized that the whole matter is too complex and contains too many varied elements to allow any entirely satisfactory general solution.

SOME fifteen years ago, recognizing the advisability for standardization of certain requirements in connection with their work, the steel mill engineers took up the question of choice of frequency. At the time all the electric power used by the steel mills was produced in their own plants, and, in many cases, such plants were of relatively large capacity compared with central stations. Apparently there was no question then regarding advisability of the generation of their own power, as this was the only way in which they could obtain electric power.

At the time there were only two frequencies in general use in this country, namely, 25 and 60 cycles. The steel mill engineers, therefore, confined themselves to a comparison of these two frequencies, and their fitness for steel mill work in general. Various applications of electricity to steel mills then in use, and in contemplation, were gone into quite fully. The manufacturers of electric and other machinery were consulted quite fully regarding the possibilities of the various types of apparatus and equipment. At that time there were three conditions of service which required special consideration, namely, (1) the operation of large very low-speed induction motors: (2) the transformation from alternating to direct current; and (3) the parallel operation of low-speed gas-engine-driven generating sets. These three conditions will be gone into more fully.

At the time that this study was made, much of the heavier service of the steel mills was contemplated at relatively low speeds with direct-connected motors, or with as little gearing as possible, on the basis that large, high-speed, high-power gears would not be satisfactory. As motors up to 6000-h. p. nominal rating, with speeds of 75 to 90 rev. per min. were considered necessary in certain applications, it appeared, from all points of view, that for such work 25 cycles was far better than 60, both from the standpoint of the general performance and the first cost.

In transformation to direct current, both synchronous converters (or "rotaries" as they are often called) and motor-generators were recognized as possible methods. With synchronous converters, 25 cycles offered by far the better proposition, compared with the 60-cycle synchronous converters of that time; whereas, with motor-generators, there was not much difference. With induction-motor drive, for motor-generator sets, naturally the lower frequency appeared to offer advantages, while with synchronous motor drive, the 60-cycle possibly was better. It must be borne in mind that in those days the high-speed d-c. commutating-pole generator, as we now know it, was not yet developed, and, therefore, with the then relatively low speeds of motor-generator sets, 25-cycle synchronous driving motors were fairly comparable with 60 cycles, while with induction-motor drive the advantage naturally was with 25 cycles. The coming of the commutating-pole d-c. machines, with consequent very much higher speeds, has greatly changed the situation, as will be referred to later.

To be presented at the 369th meeting of the A. I. E. E. in joint session with the A. I. S. E. E., Pittsburgh, Pa., April 16, 1921.

The third condition mentioned, namely, parallel operation, is one which concerned, principally, gas-engine drives. It was the belief that by using furnace gases with suitable large, low-speed, gas engines, the most economical generation of power would be obtained. The Gary plant is an illustration of this early tendency. It was well-known, at the time, that, with 25 cycles, parallel operation of alternators, with gas-engine drive, was a much easier proposition than with 60 cycles, and even with 25 cycles there were some doubts regarding successful paralleling.

This Gary plant should be referred to further as an illustration of certain extreme conditions undertaken in some of the earlier pioneering in electrification of steel mills. Everything was more or less new and special in this electrification and this was frequently cited as an illustration of an entirely electric-driven steel mill. In this early plant, there were many conditions of motor drive which, even with very low-speed motors, still required huge gears for still further reduction in speed. Some of the ultimate speeds, at the load, corresponded to six to ten revolutions with direct motor drive, obviously representing impossible conditions as far as direct motor applications were concerned. Even with gearing, the conditions of motor drive were such that 60 cycles would have represented impracticable conditions, so that 25 cycles was a practical necessity in this plant as designed. This Gary plant had a very decided influence in fixing 25 cycles as a standard for steel mill work.

Taking all the various conditions into consideration, the steel mill engineers decided definitely upon 25 cycles as their future standard for generating plants. A standard voltage of 6600 was also decided upon, although this was not considered as of first importance, but practically amounted to setting an upper limit. It was felt that there would be considerable use for lower voltages, such as 2200, and in fact, experience has shown that, in the smaller plants, 2200 volts is used more than 6600.

This choice of 25 cycles at that time, was undoubtedly the correct one, with the knowledge and experience available, and it may be stated emphatically that no real mistake was made in this choice of frequency. It may be said, moreover, that if 60 cycles had been chosen, instead of 25 cycles, at the time, it is probable that steel mill electrification would have been greatly handicapped in many ways and would not have reached nearly the stage of development that has been attained today.

However, new conditions have arisen in recent years which have changed the complexion of the problem to a certain extent. Fifteen years ago it was believed quite generally, that 25 cycles would be the future power frequency of the country on account of its general advantages in generation, transmission, utilization and transformation to direct current. If this was true of the general problem, it applied still more positively to the steel mill situation. The whole trend for large power service seemed to be toward 25 cycles; but, for lighting purposes, 60 cycles was favored as being by far the more desirable frequency.

From the central station standpoint, however, the situation gradually changed. One of the big handicaps of the 60-cycle system was in the greater difficulties in transformation to direct current. The 60-cycle synchronous converter, while operative in a fairly satisfactory manner in some applications, was considered quite unsatisfactory in others. This, therefore, meant that motor-generators were required, to a considerable extent, in connection with 60-cycle generating plants, while with 25 cycles, synchronous converters were used almost exclusively. Thus the large generating plants for operating d-c. railway service and those for operating the three-wire d-c. Edison systems went almost exclusively to 25 cycles, mainly on account of the advantages of synchronous converters over motor-generators. However, improvements in the 60-cycle synchronous converter, making it a better operating machine, appeared about fifteen years ago, but nevertheless the machine, being of the non-commutating pole type, was of relatively low speed, with many poles, and was unduly complicated and expensive and inefficient. The coming of the commutating poles in d-c. generators was naturally followed, although several years later, by the use of similar poles in synchronous converters beginning about 1911. At first the use of commutating poles on synchronous converters was considered as unnecessary, and simply in the nature of a refinement, due to their relatively low speeds, and there was some truth in this. However, the use of commutating poles on synchronous converters immediately opened the way to very much higher speeds, so that within a year or two after their real introduction, the speeds of both 25 and 60-cycle synchronous converters began to climb at a rapid rate. Here, however, the 60-cycle converter had the advantage, for soon the 25-cycle machines reached their limiting minimum number of poles; whereas the 60-cycle machine could go to materially higher speeds before reaching such limits. Consequently, in this race toward higher speeds, the 60-cycle synchronous converter, in the smaller capacities, especially, soon outran the 25-cycle, while in the larger machines, it made such a good showing relatively, that it put the 60-cycle generating system nearly on a par with the 25-cycle from the standpoint of transforming to direct current. Here was a big step in favor of 60 cycles.

In the development of induction motors, the tendency also was toward higher speeds. In the small sizes of 25-cycle induction motors, there is not much choice in speeds on account of the few combinations of poles which are possible. Here 60 cycles presented material advantages in offering very much higher

speed machines for general power purposes, with the resultant lower first costs. 1200 and 1800 revolutions, corresponding to six and four poles, respectively, became common practise on 60 cycles; whereas 750 rev. per min. was practically the nearest corresponding 25-cycle machine. Of course, two-pole, 1500 rev. per min., 25-cycle machines are possible, but it happens that, for constructive reasons, the two-pole machine does not show any material advantage in cost or otherwise over the four-pole machine.

From a third standpoint, namely, power generating units, 60 cycles also soon presented advantages. In the earlier days of the turbo-generator, the 25-cycle, two-pole, 1500-rev. per min. unit was favored over the 60-cycle, six-pole, 1200-rev. per min. of corresponding capacity. However, in the race toward higher speeds, which has occurred in the turbo-generator practise as well as in other lines of electrical design, the 1200-rev. per min., six-pole machine was dropped in favor of the 1800-rev. per min., four-pole machine, thus putting the advantage somewhat in favor of 60 cycles. Moreover, up to 5000 kw., a 3600-rev. per min., two-pole machine at 60 cycles became possible; whereas the best that the 25-cycle frequency could offer was 1500 rev. per min.

In transformer development, in the early days, it looked at first as if 25 cycles had all the advantage, due to the fact that the iron losses were relatively much lower and, therefore, the iron in the magnetic circuit could be worked at very much higher flux densities. However, with improvements in the quality of transformer steel, such as the introduction of silicon steel, it was found that with either 25 or 60 cycles the flux densities could be worked up to such a point that saturation of the magnetic circuit, and in consequence the magnetizing current itself, became one of the limiting conditions. Thus 25 cycles represented simply lower losses in the transformer iron, which were more than counterbalanced by the increased quantity of iron required, so that the advantage began to be on the side of the 60 cycles; and in later development the 60-cycle transformer, as a rule, has proved to be materially smaller, lighter and cheaper than its 25-cycle competitor.

Thus it may be seen from the few indications given above, that there were strong reasons for the trend toward 60 cycles for general power generation and distribution. The transmission advantages at first seemed to be in favor of 25 cycles. However, transmission voltages soon rose from 11,000 to 22,000, 33,000, 44,000, 66,000, 110,000, 132,000, 154,000, and now 220,000 is to be tried out soon, and with these higher voltages the 60-cycle transmission has proved to be sufficiently satisfactory; so that taking generation, transformation, transmission, distribution and the nature of the load into account, the sum total of the advantages has been considerably in favor of 60 cycles.

Another consideration must be taken into account, namely, fifteen to twenty years ago large control stations for general power supply were almost unknown. There were lighting stations and there were railway stations and there were power stations furnishing individual industries, but there were practically no central stations for the general supply of power for all purposes, as have developed during the past few years. With the gradual recognition of the advantages of centralized power plants, the smaller lighting and general power distributing stations began to expand and reach out toward the isolated and special service plants. Gradually as the central stations increased in capacity, they began to make special power rates to the railway companies and to the industrial plants, which were better than these plants could obtain from their own generating plants. Consequently, there was soon a tendency toward shutting down the individual plants, with purchase of power from the central plant. This action has been cumulative, for the more load that was taken over by the central plant, the bigger the central plant became, and the better rates it could make, etc. In this growth the tendency has been very largely, and in recent years almost exclusively, toward 60 cycles as a general purpose frequency.

Naturally, in reaching out for more load, these large central power plants have gone after the steel industry along with other industries, and here is where the steel mill problem of frequency has become prominent. As many of these steel mills, especially the older ones, are already equipped for 25 cycles, the problem has been that of best adapting the 60-cycle frequency where power is to be purchased.

In the former days, the steel mill could compete quite favorably with the central station in the cost of power. However, with the increased growth of the central power stations and their lower rates for power, the steel mills are naturally strongly tempted toward the purchase of power. Even though the steel power plant may be able to generate power as cheaply as it can be purchased, it still is not, in itself, an attractive investment as capital is not, as a rule, invested in the steel industry without the expectation of a reasonable return. As some of the steel mill engineers have said, their business is to produce steel and not manufacture power, and, therefore, naturally they cannot compete in many cases with those whose sole business is the manufacture and sale of power.

One condition which now lends itself toward the use of 60 cycles in steel mill work has been the increased use of gearing, thus allowing higher speed motors. For many kinds of service, gearing is now used where direct connection, a few years ago, was considered as the only method. In consequence, the speeds of the motors used in steel mill work will average much higher than a few years ago.

On the other hand, however, there are certain pre-

judices against large gears for heavy service, based to a large extent upon more or less unfortunate experiences. However, through greater experience and with more suitable types of gears, this prejudice is disappearing to a very great extent. As in everything else, there has been considerable development in the gear situation to meet many of the applications, and while there may be individual cases where gears are not looked upon favorably, yet it must be admitted that the general tendency in recent years has been quite strongly toward higher speed motors with gearing. Regardless of whether or not it represents the best engineering, the trend is toward such gearing, and, as a rule, where a trend persists it must sooner or later become recognized as desirable practise. The law of the survival of the fittest holds in steel mill machinery as well as in everything else.

Of course, it must be borne in mind that operative low-speed motors can be built as well for 60 cycles as for 25 cycles, but with either lower power factor or with high cost. In some cases, lower power factor may not be an important item. To state it plainly, with equal power factors, a low-speed 25-cycle induction motor is inherently smaller and cheaper than the corresponding 60-cycle motor. This is a fundamental difference. On the basis of equal costs of motors, with quite different power factors, additional cost of power factor correction should be included to make the two entirely comparable. It is, however, only in the low-speed induction motors that the 25-cycle frequency represents any material advantage. If, therefore, a plant should be made up largely of low-speed induction motors, the 25-cycle frequency would represent a most nearly ideal arrangement. However, there are very few plants, if any, where the larger part of the total power is utilized in such motors. Therefore, taking all the other service into account, it will probably be found that there are very few plants where 60 cycles cannot now make practically as good showing as 25 cycles. In other words, where the low-speed service represents but a relatively small part of the total service, it may be better to make some sacrifices in this smaller part to the advantage of the whole.

The question of purchase of 60-cycle power is dependent, of course, upon many conditions. In the Pittsburgh district, for instance, the total electric power used in the various steel mills may represent the equivalent of a huge power plant in itself. In consequence, if the various mills were to combine their power plants into one general plant, the capacity of such plant and the conditions of operation would probably be such that it could compete quite favorably with any large central station, and in such case 25 cycles could be the frequency. Moreover, this would remove the manufacture of power from the mills themselves and place it in a plant whose sole business would be the manufacture and supply of electric power. It may be suggested at this point, that, at present, furnace gases are used to a greater or less extent under the boilers for power plants and that with the power plant placed elsewhere these gases would be wasted. However, there is not much doubt but that other uses would be found for such gases, and, in fact, some of the steel mills at present can find uses for all the furnace gases without burning them under the boilers.

However, in considering a single large power plant, the Pittsburgh district represents very unusual conditions in that there is a concentration of many huge steel plants within one relatively limited district. A combined steel power plant in the Pittsburgh district would, therefore, represent a very special rather than a general condition and would furnish the solution of the problem for only one general district. In other districts the problem of 60 cycles versus 25 cycles would still hold and would have to be met. Therefore, it is the general problem rather than a special one which should be considered broadly.

With this question of purchase of power before them, a number of the steel mills throughout the country which have been planning to increase their power plants, are faced with the question of installing additional plant at 60 cycles instead of 25 cycles; also, with their existing 25-cycle plants, the purchase of additional power at 60 cycles involves numerous problems in the application of such power to the existing equipment. Various suggestions have been made from time to time as to how to handle this situation in its various forms. Probably as good a way as any to look into the problem would be to classify the various methods by which the double-frequency situation could be met. These methods may be given as follows, the order in which they are given, however, not representing their expediency or importance.

1. Rebuilding, or allowing to become obsolete, the existing plant and replacing entirely with 60 cycles.

2. Conversion of 60-cycle purchased power to 25 cycles by frequency-changers and operating in connection with existing plants. This retains the advantage of the existing 25-cycle system but means, however, considerable losses due to the frequency-changers.

3. Allowing the existing 25-cycle plant to remain in service, and installing new generating and motor equipment for 60-cycle. This would allow purchased 60-cycle power to be utilized in connection with the new generating plant. This, however, involves a more or less mixed system throughout the plant.

4. Retaining the existing 25-cycle plant for those parts of the service where 25 cycles is materially better, and changing other parts to 60 cycles for use on purchased power. This could be continued until the old plant and equipment became obsolete. This would probably mean a mixed system throughout the mills for years to come.

5. Utilizing the existing plant within certain areas and applying 60-cycle purchased power to extensions and new areas. This involves a double system, but not a general mixture of two systems in the same areas. Eventually if the purchased power proves more satisfactory than the local supply, the latter could gradually become obsolete. This means, however, that in the new areas the 60-cycle frequency would be applied to low-speed motors as well as all other apparatus.

Looking at the matter broadly, it does not seem advisable to generate two separate frequencies in the local plant. In other words, if 25 cycles is the existing frequency, it is not desirable to put in an additional generating plant at 60 cycles, unless such new equipment is to be of greater capacity than that already installed. In this latter case it might be advisable to put in the additional plant of 60 cycles, simply with the understanding that the older small 25-cycle plant will soon be superseded entirely. In other words, the only condition under which the two frequencies should be mixed in the one generating plant, is where one of them is to be abandoned entirely within a reasonably short time. Wherever the additional plant, however, is to be less in size than the plant already installed, or simply represents the normal growth, then it appears that it would be better to put in the additional plant at the same frequency, rather than mix the two frequencies.

Some of the large central stations throughout the country have encountered a similar problem. In some of these cases both 25- and 60-cycle generating units have been installed in the same power plant, but as a rule, they supply quite different service and areas. For instance, the 25-cycle service will be utilized almost entirely by conversion to direct current, and within a given district this will apply exclusively. In other cities the 60 cycles may be represented by entirely separate power plants supplying outlying districts mostly, a large part of the application being by direct service instead of by conversion to direct current. As far as the writer knows, in general, the two services are not mixed indiscriminately. In the earlier days where 60-cycle service came into considerable demand in connection with 25-cycle plants, frequency-changers for giving 60 cycles were installed in many cases. As the 60-cycle service grew, instead of adding more frequency-changers, whose sole function is to change frequency, not to generate power, the practise has been to install 60-cycle generating units often in separate power plants, the existing frequency-changers then being used as a tie between the two plants. In those cases where the capacity of the two power plants has been very considerable compared with the capacity of the frequency-changers tying them together, there have been certain conditions of unusual stresses in the frequency-changers at times of severe load conditions. In other words, if the link, tying the two plants together, is a relatively weak one, sometimes it may be broken. This problem of the two frequencies has been one of long standing with the central power stations, and as the present solutions are more or less a development from experience, this is possibly an indication that steel mills should follow along somewhat similar lines.

It has been suggested that in the application of 60 cycles to steel mills, this might be used largely for one kind of service such as the motor-generators or synchronous converters, for producing direct current. In this way the 60-cycle service need not be distributed so generally throughout the mills, but would simply be supplied to the converting machinery which is not scattered through the mills in the same way as the motors. Moreover, the modern 60-cycle synchronous motor-generator is just as cheap and economical as its 25-cycle competitor, or cheaper in some cases, while the 60-cycle synchronous converter, if transformers are included, approaches pretty close to the 25-cycle in general operating characteristics.

In existing mills, however, changing to 60 cycles would mean replacing or remodeling, at very considerable expense, the existing motor-generators and synchronous converters, and unless the future growth of such apparatus is to be very large compared with that already installed, this reconstruction or replacement might prove in the end to be relatively expensive, perhaps as much so as the installation of frequency-changers, which would allow the continuation of the existing 25-cycle frequency. Even if the existing machinery is more or less out of date, unless it has uneconomical characteristics, it can probably be kept in service for many years to come, for much of this machinery is well built and of durable construction and may still have twenty to thirty years of good operative life. In fact, some of the motor-generators and synchronous converters which have been in operation for ten to twenty years in steel mills appear to be as good as when first installed, and it will be difficult to justify their obsolescence and replacement.

Something might be said further regarding frequency-changers. As stated before, the function of the frequency-changer is simply to change frequency at a considerable expense in power. There are other objections outside of inefficiency which count against the frequency-changer, but these probably would not be dominating or controlling in themselves. On the face of it, the frequency-changer seems to furnish such a simple solution of the frequency problem that in some instances it might pay to sacrifice other considerations in favor of simplicity.

It must be kept in mind, that there are no means for getting the exact 60 to 25 relation with an economical type of machine, for the numerical ratio of 60 to 25 only allows a 24-10 pole combination, which represents a rather low speed except for units of enormous capacity. If any other more economical combination of poles is chosen, such as 10-4 or 14-6,

then, with a 60-cycle supply system, some other frequency than 25 cycles will be obtained. The 10-4 pole combination gives 24 cycles, while the 14-6 pole combination gives 25.7 cycles. Therefore, for either of these combinations, it would be necessary to change the steel mill frequency slightly, for it would be almost impossible to get any general power company to change its frequency of 60 cycles. Naturally, if either of the above combinations were to be adopted, the 10-4 pole would be preferable from the standpoint of the frequency-changer itself. However, there might be some question regarding the use of 24 cycles instead of 25 cycles in steel mill applications, for this means a general reduction of 4 per cent in the speed of all synchronous and induction motors. Thus the choice of the most advantageous speed for the frequency-changer may possibly represent a material disadvantage in the motor equipment. Again, the use of the 14-6 pole frequency-changer would mean increasing the mill frequency about 3 per cent, which should not be as objectionable as a reduction of 4 per cent. However, the 14-6 pole combination would not represent nearly as cheap frequency transformation.

As affecting the cost of the frequency-changer and its losses, there may be considerable saving over the installation of corresponding capacity in additional power generating plant. In installing new or additional power plant, the cost of the electric machinery represents but a small part of the total cost and, unquestionably, the extra buildings and equipment, to go with the frequency-changer, would be very materially less than that of additional generating plant. This saving in first cost, in some cases, might go a long way toward offsetting the losses of the frequency-changer, especially in those cases where 60-cycle power can be obtained at a very low rate. However, no definite statement can be made as to the comparative costs, because each case would have to be worked out individually.

As soon as two or more frequency-changers are to be installed in one plant, these to be operated in parallel with each other and with the existing generating plants, then complication comes in, possibly to such an extent as to lose most of the simplicity of the scheme. The synchronizing and proper paralleling of two or more frequency-changers with each other and with their respective power plants, is one of the "fussy" things which can be carried out successfully, but which nobody likes.

Attention should be called to the fact that if any particular combination of frequency-changer sets is chosen such as represented by 10-4 poles, or by 14-6 poles, then this exact ratio must be retained throughout, if additional frequency-changers are ever to be added to the plant. It is obviously impossible to parallel two combinations of poles which do not have the same ratio.

As to the capacities of such apparatus which are practicable in single units, 10-4 pole sets of 5000-kv-a. capacity have been offered recently by manufacturers. However, for larger capacities than 5000 kv-a. certain difficulties arise, as the next possible pole combination is 20-8, which represents just half the speed. In consequence, even with a 10,000-kv-a. set, halving the speed will probably more than offset the gains in cost and efficiency resulting from larger capacities. One would assume, in consequence, that two 5000-kv-a. units would be preferred to one 10,000-kv-a., and presumably this is correct, if the two units can be operated independently. For parallel operation, however, the added complexity might be considered sufficient to offset a slight increase in cost of the larger single unit.

For costs and efficiencies of such apparatus, the following very approximate figures are suggested.

For a 5000-kv-a. set including auxiliaries, switchboard appliances, etc. from \$10.00 to \$11.00 per kv-a. The combined efficiency will be approximately 92 per cent or better at full load and 89 per cent or better at half load.

For a 10,000-kv-a. set, having 20-8 poles, the cost per kv-a. could be taken roughly at \$11.00 to \$12.00. No figures for efficiency have yet been worked out.

Neither of the above approximations includes cost or efficiency of step-down transformers.

There is one other class of electric machinery used in steel mills where the effect of frequency has not yet been considered, namely, in the induction-motor speed-regulating sets which are coming into use to a considerable extent in recent years. There are three types of such speed-regulating appliances in use today, all of them requiring commutating machinery, namely, (a) those in which the secondary electrical power of the induction motor is transformed into mechanical power and utilized as such; (b) where the secondary electrical power is transformed into direct current and utilized; and (c) where the secondary power is transformed from the variable or adjustable frequency of the secondary to some fixed frequency such as that of the line and thus utilized. The first of these schemes involves polyphase commutating type motors; while the second requires synchronous converters; and the third requires commutator type frequency-changers, which are a more recent development than the other types of machinery mentioned.

From the standpoint of commutation, (a) and (c) present considerable advantages in first cost, general performance and efficiency at 25 cycles, as compared with 60 cycles, while method (b), involving synchronous converters, makes its best showing at 60 cycles, although all three arrangements are praticable at both frequencies. Arrangements (a) and (c) allow satisfactory operation both above and below the synchronous speed of the induction motor; whereas, (b),

heretofore, has only been worked below synchronism, although auxiliary means may be found for this scheme just as with the other two, for successfully passing the synchronous speed condition. All these methods of speed control will doubtless be used to a considerable extent, depending upon the conditions and the applications, but as they can be operated successfully on both 25 and 60 cycles, apparently they will have no controlling influence on the choice of frequency.

In conclusion, it may be said that there is no good general solution to this frequency problem and each case must be handled on its merits, taking the future tendencies and growths into account. In many cases it appears that the large existing 25-cycle local systems should be retained at least until such time as the need for replacement is more obvious than at present. Unless the future service of the mill shows strong inclinations of going almost entirely to 60 cycles a mixed generating plant is not to be recommended. In those cases where existing 25-cycle power and purchased 60-cycle power are both to be used, they should at first have their own individual services or areas, as far as possible, to avoid indiscriminate mixing of services throughout the mills, and to avoid frequency-changers, with their attendant losses, unless conditions are such as to warrant their use. In general, where both frequencies are liable to be used for some time to come, and there is any real necessity for a tie between the two, then frequency-changing becomes a necessity. However, as central station service has now become quite reliable there is not the need for a tie between two frequencies that was formerly the case, so that doubtless, in many cases, frequency-changers can be dispensed with. In case of a new plant, even where it expects to generate its own power, in general it should be installed at 60 cycles, if *located in a 60-cycle district,* simply on account of future possibilities. There is no question whatever that future central stations will supply power for general purposes, at 60 cycles, within certain large districts, the trend being too strong to be changed or controlled. In other large districts it will be principally at 25 cycles, as in the territory served by Niagara, for instance. There will be still other cases where both frequencies will be used, simply because the field for 25 cycles is already so large that 60 cycles cannot replace it. In New York City, for instance, 25 cycles is already in use on such a vast scale (1,099,600 kv-a., 25 cycles, and 217,000 kv-a., 60 cycles) that it may be almost a lifetime before the 60-cycle service overtakes it. But the present growth in 25 cycles appears to be limited to existing plants, many of which may never be replaced by 60 cycles. In consequence of this mixed service, the ultimate solution of the general supply problem may mean 60 cycles for general purposes with 25 cycles as an auxiliary supply. It may be assumed that in those cases where 25 cycles presents such advantages that the consumer will put in his own generating plant, if necessary, to obtain such service, that eventually the general power service will find some means for supplying the individual case.

FOREIGN PATENTS

Those inventors who have interest in foreign patents should note that at the present time many changes are being made in continental and other patent laws, which need to be watched if it is desired adequately to protect the inventions in Europe or in the greater part of the world. A new law has recently been provided in Jugo-Slavia which brings this matter into prominence. Protection of industrial property is now uniformly regulated for the whole of the kingdom of the Serbs, Croats and Slovenes, and all protections which have been obtained in any part of Jugo-Slavia, either in the former kingdom of Serbia, or in Austro-Hungarian territories, which were in force at the end of last year, must be re-filed if it is desired properly to protect the invention throughout the kingdom of Jugo-Slavia.

The provisions of the new law correspond largely with those of the old Austrian Patent Law, and therefore exclude from protection matters which are Government monopolies. It is not usually known in this country how far these monopolies extend, so that it is well, before deciding on any particular patent application to be lodged in the new kingdom, to inquire of authorized parties. Explosives, tobacco, certain kinds of paper, and petroleum are among the subjects for which valid patents cannot be obtained.

Among other countries in which modifications have been made in connection with Patent Laws recently there may be named Roumania, Esthonia, Greece and Hungary.—*The Engineer,* London.

GEORGIAN WIRELESS STATION

According to an issue of the Near East for February 3, 1921, the Georgian Ministry of Supplies has concluded an agreement with a French trading and financial company for the erection of a powerful radiotelegraphic station in Georgia, by means of which it will be possible to communicate within a radius equivalent to the distance between Tiflis and London. The new station will connect Georgia with large European centers, such as Paris, London, Rome, Moscow and others.

According to the agreement, the Ministry of Supplies is to pay for the erection of the station by means of a consignment of tobacco. The station is to be erected within the next six months. At the same time another agreement under the same conditions was signed for the erection of four wireless telephone stations in various parts of Georgia. The central wireless telephone station will be erected in Tiflis.

Carrier Current Telephony and Telegraphy

E. H. COLPITTS and O. B. BLACKWELL
Western Electric Co. American Telephone & Telegraph Co.

This paper briefly outlines first the history of the development of carrier multiplex telegraphy and telephony. The fundamental principles underlying particularly the newer developments of the art are then discussed. Consideration is likewise given to the propagation characteristics of open wire lines, including those containing intermediate lengths of cable. Commercial types of apparatus and actual installations are then described and a brief statement made as to further applications of the art.

THE carrier method of multiplexing telephone and telegraph lines is technically one of the most interesting and important of the developments which have been perfected in the art of electrical communications during the past few years. In this paper we are giving a brief sketch of the development of this art, an explanation of the principles on which it is based, and a description of the applications which have been made in the plant of the Bell Telephone System.

In a carrier multiplex system, a number of separate telephone, telegraph or signaling messages are superimposed simultaneously on a single electrical circuit by employing a separate alternating current, usually called a "carrier current," for each of the separate messages. This carrier current is made to vary in accordance with the variations of current representing the telephone, telegraph or signaling message. The different carrier frequencies which are superimposed on a circuit must differ sufficiently in frequency so that they may be separated from each other at the terminals by the use of proper electrical circuits. Each carrier may be of either audible or ultra-audible frequency, but its frequency must be higher than the highest frequency represented in the message to which it corresponds. These currents are known as carriers, since in a sense, they may be said to "carry" the telephone, telegraph or signaling currents by which they are controlled.

The underlying principles of such systems are old in the communication art and indeed go back to the date of the invention of the telephone itself, for it will be recalled that it was Bell's experiments with the vibrating reed type of multiplex telegraph system which led to his discovery of the telephone. A short history of the art during the forty odd years that have elapsed between the conception of its possibilities by the early communication pioneers and the present realization of their hopes is given below under the heading "Historical."

In looking back over the early history of the carrier art it is now clear that the development of successful multiplex carrier systems had necessarily to await not only the evolution of the fundamental ideas for carrier operation, but also the development of radically new types of apparatus and the developments in electrical wave transmission over wires which have characterized the recent progress of long-distance telephony.

The telephone and telegraph systems which are described in this paper are in daily use over long toll circuits in the Bell telephone system. The telephone installations in service furnish simultaneously as many as four two-way telephone conversations over each circuit in addition to the telephone and telegraph facilities normally afforded by the circuit. The telegraph systems in service are arranged to furnish as many as ten duplex carrier telegraph circuits over each circuit in addition to the telephone and telegraph facilities normally afforded by the circuit. These figures do not indicate the maximum numbers of facilities which it will be found economical to employ ultimately, but cover the facilities furnished by the systems which are now commercially employed.

The increased circuit facilities obtained in this way are, in general, up to the high standards set for the best grade of long-distance circuits. They are relatively stable and are maintained by the regular telephone plant personnel. The carrier circuits, both telephone and telegraph, are so designed that as circuits they fit in completely with the more usual circuit facilities of the telephone system. They may be connected with each other and with ordinary circuits, and, in general, present much the same degree of practicability and flexibility of operation as do the more usual forms of circuits.

While the development has thus succeeded in making available to the communication art new types of circuit facilities, these facilities can only be made to meet the high standards required in a public service plant by the use of correspondingly high-grade equipment which, unfortunately, is correspondingly expensive. Indeed, the cost of these systems, at least at present, is such as to make their use economical only over relatively long toll circuits. For short-distance toll service, and for local exchange service, the equivalent facilities can be provided more cheaply by the older methods.

Historical

As indicated above, the multiplex carrier art had its origin in the harmonic telegraph systems dating back to the time of the invention of the telephone itself. With such alternating-current telegraph sys-

Presented at the 9th Midwinter Convention of the A. I. E. E., New York, Feb. 16-18, 1921.

tems are associated the names of Gray, Bell, Van Rysselberghe, Edison and Mercadier. The multiplex feature of these systems is well illustrated by Fig. 1, which is a reproduction of a diagram of Elisha Gray's system published[1] in 1886.

In this figure, the circles numbered 1, 2 and 3 represent vibrating reed transmitting instruments

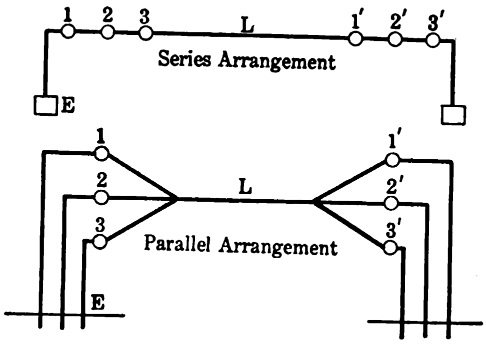


Fig. 1
(Multiple Harmonic Telegraphy)

while those numbered 1′, 2′ and 3′ represent the corresponding receiving electromagnetic reeds. When one of the transmitting reeds is vibrated, the electrical waves sent out set into oscillation the correspondingly tuned receiving reed which thus gives out an audible note. The systems invented by these pioneers are all characterized by the use of the mechanical resonance of tuned reed instruments for generating and selecting the carrier frequencies involved. This type of system has been more fully developed by Mercadier.

The Art of the 1890's. Shortly after 1890 there occurred the next outstanding development in this art, namely, the use of electrical resonance instead of

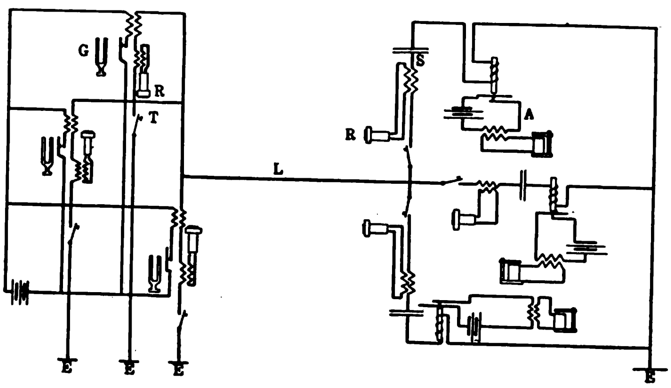

Fig. 2
(Pupin—1892)

mechanical resonance for selecting the carrier frequencies. An interesting piece of technical history is disclosed in the manner in which several investigators, Professor Pupin, Hutin and Leblanc, and John Stone Stone, independently invented about the same time the electrical method of selection of a plurality of carrier frequencies. Pupin was adjudged the earliest inventor in the United States. His original system is illustrated in simplified form in Fig. 2.[2]

In order to permit the successive figures in this historical discussion to be readily followed, a uniform system of lettering their important parts has been employed. These conventions are as follows:

G = Generator of carrier current.
T = Telegraph key, telephone transmitter or other carrier modulating device.

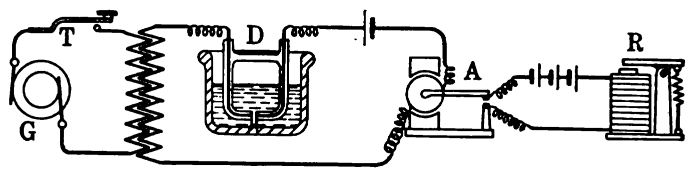

Fig. 3
(Pupin—1898)

L = Line.
S = Selecting or tuned circuit.
D = Detector.
A = Amplifier.
R = Receiver.
D R = Detecting receiver.
E = Earth.

By following this lettering Fig. 2 will be readily understood. It will be noted that at each end the line branches into three parts, and that each circuit is tuned by capacity and inductance to a particular frequency. It will be seen, furthermore, that each of the channels derived in this manner is arranged for sending in both directions, although not simultaneously. Each generator consists of a self-excited tuning fork driving a contact or a microphone transmitter. Re-

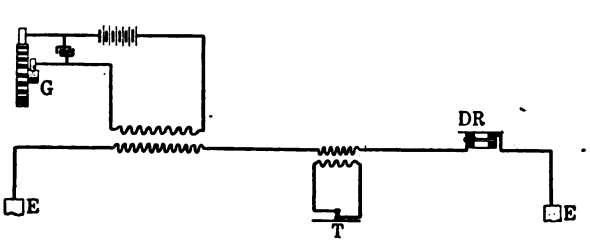

Fig. 4
(Hutin and Leblanc—1892)

ceiving is accomplished either by a telephone receiver or by a vibrating reed device which is operated by a microphone amplifier.

Pupin also invented an electrolytic detector for use in such alternating-current telegraph systems as shown in Fig. 3.[3]

The function of this detector was to rectify the alternating current and thus enable a d-c. telegraph relay to be operated from the rectified current. This marked the beginning of the use of separate

3. From U. S. Pat. No. 713,044, 1902.

devices for performing the two primary functions of carrier receiving; (1) that of reproducing from the carrier the current variations which represent the original signals, and (2) that of indicating the signals, as by a relay or telephone receiver. The separation of these two functions is important in the carrier art because it permits the place at which detection is effected to be separated from that at which the indication or interpretation occurs.

While the contributions up to this time were concerned primarily with telegraphy, they were very soon carried over into the field of telephony (still in the early 90's) by such pioneers as Gibboney, Hutin and Leblanc, and Stone. Their predecessors were concerned with the use of carrier frequencies of the order of a few hundred cycles, whereas, these inventors appreciated the necessity of employing for telephony carrier currents sufficiently high in frequency to preserve the characteristics of the voice currents. Thus we find suggested at this early date the use of carrier currents in the tens of thousands of cycles, which values have since proved to be in the preferred frequency range. Hutin and Leblanc so simply illustrated the use of relatively high-frequency alternating currents for telephony that it is useful to reproduce their early diagram as shown in Fig. 4,[4] for the purpose of obtaining in our discussion an appreciation of the principles involved.

This is a carrier telephone circuit of the simplest type, arranged for a single one-way transmission. Connected in the line are three elements, the generator of the high-frequency currents *G*, the voice-actuated modulator *T*, and the detector-receiver *D R*. The generator is a high-frequency commutator; the modulator is a microphone transmitter; and the receiver which is of the dynamometer type serves the double function of detection and of translation into sound waves.

Multiplex operation of this type of carrier telephone channel as devised by these French inventors at the same time (about 1892) is also representative of these early contributions to carrier telephony and is reproduced in Fig. 5[5]. Here we have the carrier telephone channel of Fig. 4, arranged for multiplex operation by the use of electrical selection, each of the carrier circuits being tuned by capacity and inductance to its own carrier frequency.

As indicated the carrier currents of all the channels are introduced into the line at a common point through a transformer. At each terminal the line divides into four branches. Each sending branch contains a microphone transmitter *T* connected into circuit through a transformer. Each receiving branch contains a dynamometer receiver *D R*. The condenser in each transmitting circuit and the inductance in each receiving circuit were employed in tuning the channels.

The multiplex system invented by John Stone Stone[6] was very similar to those illustrated above for Pupin, and Hutin and Leblanc, and is therefore not illustrated. It did, however, contain an important improvement over those of his contemporaries in that he tuned the local branch circuit individually instead of tuning the system from end to end for each

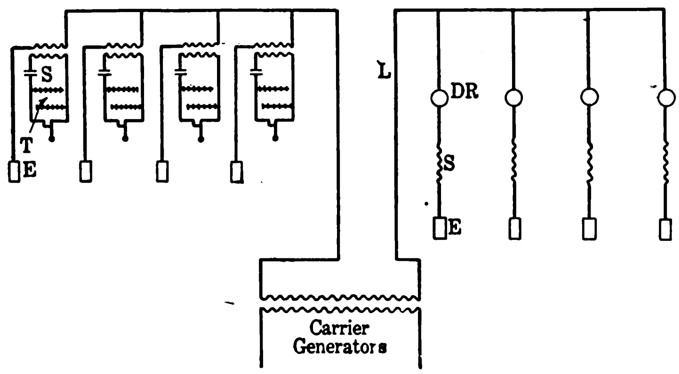

Fig. 5
(Hutin and Leblanc—1892)

carrier channel, as did Pupin, and Hutin and Leblanc (see their figures). This improvement is evident also in a system which he developed shortly afterward, especially for high-frequency transmission. This is illustrated in Fig. 6.[7]

Stone devised and tested this system in the laboratories of the American Bell Telephone Company in 1894. The high-frequency currents were generated by means of small arcs which were fed from a d-c. source through a suitable choke coil. One of the electrodes

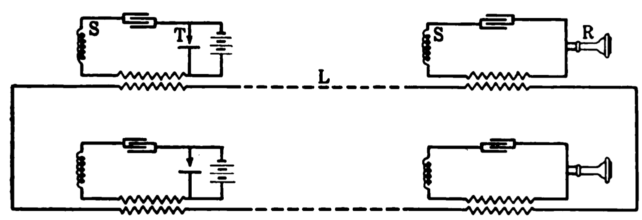

Fig. 6
(Stone—1894-96)

of each arc in Fig. 6 was made light in weight and was attached to a diaphragm which served, when acted upon by voice air waves, to modulate the high-frequency currents generated by the arc. The particular arrangement illustrated is also of interest in showing the tuned circuits at both the sending and receiving ends as associated with the line in a series manner, an arrangement which is an alternative of the parallel connections previously illustrated.

It is also of interest to note in connection with these

older multiplex telegraph systems that Van Rysselberghe recognized as early as 1886[8] the advantage of superimposing the alternating-current circuits on an ordinary d-c. telegraph circuit, thereby enabling the ordinary telegraph wires to be employed for the transmission of the multiplex system. While the idea of extending the range of frequencies employed in

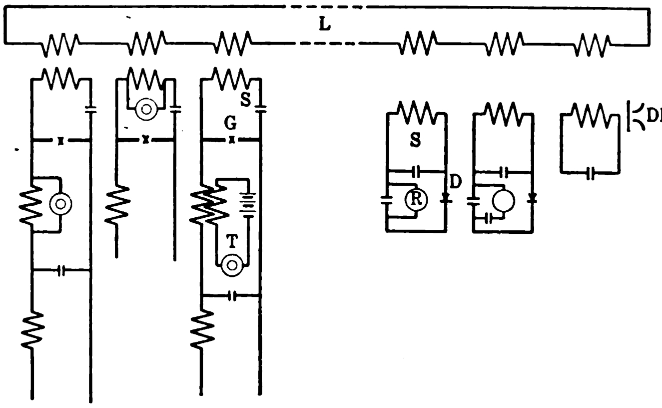

FIG. 7
(Ruhmer—1909-10)

the multiplex system down to zero frequency and thereby including the d-c. signaling circuit would naturally be obvious in a more advanced stage of the art, its invention at this early date illustrates the clear engineering appreciation these earlier inventors possessed.

It will be seen, therefore, that the foundation of the carrier art was laid back in the 1890's, at which time there had been contributed these cardinal features:

1. Electrical selection or tuning.
2. The use of continuously generated high-frequency carrier currents.
3. Modulation of the carrier, as by a microphone transmitter.
4. Detection and indication of the high-frequency currents by means responsive continuously and proportionally to the received current.

Relations of Radio Developments. With the entrance of wireless telegraphy into the communication field, the attention of those scientists and engineers who might otherwise have developed the art of wire multiplex, so well begun, as indicated above, seems to have been diverted to the new found art. The wireless art started with the use of very high frequencies, generated discontinuously by the spark method, and gradually came to use waves of lower and lower frequency, and of increasing persistency. Finally, with the use of continuously generated waves, the radio-frequency range came to overlap the frequency range earlier employed in high-frequency wire transmission. The wire carrier art started with the use of audible frequencies and extended into the ultra-audible range, where it was later met by the radio frequencies. The similarity of the history of the two developments is illustrated by the fact that the major steps, which are noted above for the early carrier art, also mark the major steps of advancement of the radio art. By reading over the four points above, keeping radio in mind, the parallel will be seen to be quite complete.

These ideas of continuous wave telephone transmission were quite thoroughly appreciated in the radio art by about 1905, although they have not been fully attained in practise until quite recently. It was natural that radio engineers should carry these ideas over to wires, using radio instrumentalities which, while different in form, operated on the same principles as did the means employed by the earlier wire pioneers.

Simultaneously with this evolution of the radio art, attention continued to be given to the older wire carrier transmission by such other investigators as Vreeland in America and Bela Gati and Maior in Europe. About 1906 Vreeland, using his well-known mercury-vapor oscillator as a generator of sinusoidal carrier currents, devised a multiplex carrier telegraph system which embodied improvements in the use of loosely coupled tuned circuits in proper relation to the impedance of the line. An engineering and commercial development of this period, as distinguished from more purely laboratory or theoretical investigations, was the so-called "Phantoplex" system devised by engineers of the Postal Telegraph Company and quite extensively employed by that company. In this system a relatively low-frequency carrier telegraph channel was superposed on the ordinary direct-current circuit. In addition to the above, attention may be called to the disclosures by Ehret and Kitsee. Ehret shows[9] a multiplex carrier telephone system including amplifiers, and Kitsee shows[10] a carrier telegraph channel operating over an ordinary telephone circuit.

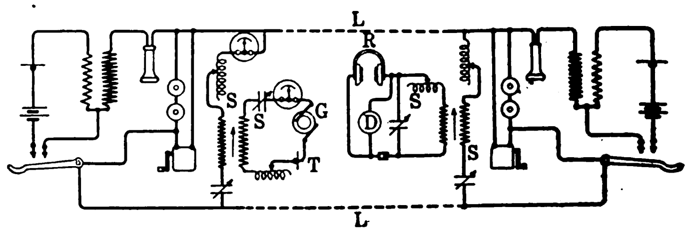

FIG. 8
(Squier—1910)

Previous to 1910, Dr. Ruhmer in Europe had undertaken experiments on high-frequency wire transmission, employing apparatus taken from the then current radio art. Ruhmer's system[11] is illustrated in Fig. 7.

8. U. S. Patent No. 363,188, 1887.

9. U. S. Pat. No. 789,087, 1905.

10. U. S. Pat. No. 666,883, 1901.

11. Belgian Pat. No. 224,008, Mar. 31, 1910; *Zeitschrift fur Schwachstromtechnik* of February, 1911; *Electrical Review and Western Electrician*, July 1, 1911.

He employed oscillating arcs as high-frequency generators, microphone transmitters as modulators, tuning at both the transmitting and receiving ends, and a radio detector in the receiving circuit.

In 1910 and 1911 Major, now Major-General, Squier carried out a set of experiments employing a carrier channel operating over a short telephone cable circuit. The announcement of his work popularized interest in this art, and the paper which he presented before the Institute in May, 1911 brought out considerable discussion.

The system which he used in his experiments is illustrated by Fig. 8.[12] This figure shows a carrier telephone channel operating over the wires of an ordinary telephone circuit. A high-frequency alternator is employed to generate the carrier current, a microphone transmitter is used as a modulator, tuning is employed at the sending and receiving ends, and a radio detector is employed in the receiving circuit.

As a part of the evolution of the radio art, there was developed in its early and somewhat crude form a device which was destined to play an extremely important part, not only in radio, but in wire communication as well, that is, the thermionic tube. Originally invented by Edison, this device was first applied as a radio detector by Fleming about 1904. DeForest in 1906 made a vital contribution by adding the grid, and thereby laid the foundation for its use as an amplifier. The history of this very remarkable device is so well covered in recent technical literature that we will discuss it here only in connection with its specific application to the carrier art.

The preceding history brings us up to about 1912. About this time an important step was taken toward the adaptation of the vacuum tube as a non-distorting amplifier by the addition of a negative grid battery by Lowenstein.

Since the above date, in addition to the active developments which were carried out in the Bell System and are described below, certain other investigators have been working in this field, among whom may be mentioned the General Electric Company, U. S. Signal Corp Engineers, Lee DeForest and certain European investigators, especially in Germany and France. In the attached bibliography will be found references to the more important publications which have been made by such investigators.

Bell System Developments. The most important developments, which have occurred since 1912 and are principally the work of the Research and Development Departments of the Bell System, may be stated as follows:

1. Development of the thermionic vacuum tube into a reliable and stable instrument for amplification, modulation and demodulation.

2. Development of the electrical filter and an improved technique of separating electrical currents of different frequencies.

3. Development of the technique of transmission over wires, particularly in connection with repeater operation and of methods for overcoming interference between circuits.

4. Development and operation of commercial carrier systems.

In considering the above developments which have led to commercial operation, it should be appreciated that in order for a carrier system to be commercially successful, it must compete on equal terms with the ordinary types of wire circuits, that is, it must have the same degree of reliability and stability, and must give the same degree of privacy and the same freedom from interference. Moreover, the system must be capable of being readily maintained and must be arranged so that it may be used interchangeably in the ordinary manner with any of the facilities furnished by the plant. All of these conditions must be met at a cost less than that of the ordinary types of circuits for similar service.

Developments in Thermionic Vacuum Tubes. The development of the thermionic vacuum tube as an amplifying element in a telephone repeater has already been described before the Institute,[13] as has also its application to radio telephony.[14]

The success which attended these two lines of development indicated that in this one device was embodied the solutions of many of the controlling difficulties that had previously stood in the way of the commercial development of carrier systems. In connection with a resonant circuit, the vacuum tube provides a compact and reliable source of continuous oscillations of readily adjustable frequency. As an amplifier of both low- and high-frequency currents, it removes the necessity for excessive line currents. As a modulator and demodulator, it provides an ideal means of impressing the voice waves on the carrier current, and of restoring them to their original form at the receiving end. These tubes have, moreover, been developed into devices which are very stable and reliable in operation, and may be maintained with only routine periodic supervision.

Electrical Filters. Another development which has been of vital importance in the success of carrier telephone systems is that of the "band-filter" invented by G. A. Campbell.[15] Without such electrical filters, it would be impossible to utilize economically the relatively low-frequency range employed in the present carrier telephone systems, or to separate various channels in this range from each other or from the ordinary telephone and telegraph channels. The simple

13. Gherardi and Jewett, A. I. E. E. Trans., pp. 1287-1345, 1919.

14. Craft and Colpitts, A. I. E. E. Trans., pp. 305-343, 1919.

15. U. S. Patents No. 1,227,113, 1,227,114, of 1917.

tuned circuits of the prior art would either introduce prohibitive distortion or, if made sufficiently non-selective to avoid distortion, would require placing the carrier channels widely apart in frequency. The Campbell filter, therefore, enabled the carrier channels to be squeezed closely together at comparatively low frequencies where the difficulties of transmission over lines are at a minimum.

Transmission over Wire Circuits. Since the attenuation over wire circuits is much greater at carrier frequencies than at the ordinary telephone frequencies, the successful operation of carrier systems is particularly dependent on the use of repeaters at comparatively frequent intervals in the line. This has required the development of high-frequency repeaters involving the application at high frequencies of all the developments of the repeater art which were described before the Institute in the paper on Telephone Repeaters already referred to. As in the case of telephone repeaters at voice frequencies, the amount of amplification which can be given by each repeater depends entirely on line conditions, such as the degree of line balance which can be maintained at the repeater point and the degree to which mutual interference between line circuits can be prevented.

This prevention of interference between line circuits required the development of more elaborate methods of transposing and adjusting them. In order to overcome the large transmission losses and irregularities introduced in open-wire lines by unavoidable sections of cable, new types of loading for cable circuits were developed for these carrier frequencies and put into practical use.

Development and Operation of Commercial Carrier Systems. In 1914, simple forms of carrier circuits, embodying the fundamentals of our present system, were successfully set up in the laboratory, and experiments carried out with them. In view of the favorable conditions which had resulted from the various developments noted above, it was decided to begin active work toward commercial carrier systems. Field measuring apparatus was developed with which the characteristics of existing telephone lines were carefully studied in the carrier-frequency range. At the same time in the laboratory the physical possibilities and limitations of the various types of apparatus and circuits were being studied. Based on these fundamental data there was developed in the laboratory a complete multiplex telephone system providing two-way telephone conversations, and operating over an artificial line. This laboratory apparatus was then taken into the field and tried out on a line between South Bend, Ind., and Toledo, Ohio. The practical difficulties always encountered were overcome, and satisfactory operation secured. At the same time satisfactory results were obtained on a simple type of carrier telegraph system between Chicago and Toledo.

The entry of this country into the war brought the work to a standstill for a time. However, the same cause created a demand for more telephone circuits between Washington and Pittsburgh. It was decided to meet this demand by a trial installation of a carrier telephone system between Pittsburgh and Baltimore, from which point cable circuits to Washington were available. In view of the urgency of the situation, the apparatus used in the earlier field experiments was adapted to equip the Pittsburgh terminal, while new apparatus was built for the Baltimore terminal. This carrier system went into service and has since been operating satisfactorily.

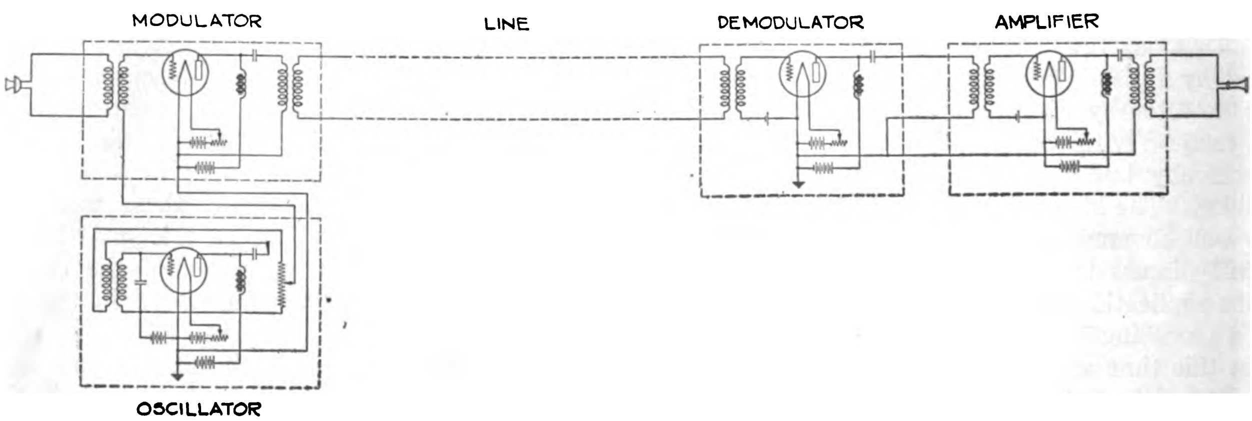

Fig. 9

Principles of Operation

General. An adequate understanding of carrier systems requires a consideration in some detail of the fundamental principles underlying their operation. Some of these principles, which are also important in connection with telephone repeater operation and in connection with radio telephony, have already been discussed at some length before the Institute in papers[16] on those subjects as referred to above. Emphasis will therefore be placed on those features which pertain more strictly to carrier operation.

16. Gherardi and Jewett, loc. cit.
Craft and Colpitts, loc. cit.

The underlying principles of carrier will be described in their application to carrier telephony. Their application to the somewhat different conditions of carrier telegraphy will be treated separately in a later section.

We will first discuss those features which are involved in a single one-way carrier telephone transmission channel, including generation of carrier current, modulation and demodulation or detection. Next will be considered multiplex operation in a single direction, involving separation of channels by selective circuits, followed by a consideration of two-way operation of single and multiplex channels. Next will be presented an explanation of another type of system in which no unmodulated carrier current is transmitted over the line and of a special mode of carrier current generation particularly adapted to this system. Finally the repeaters used for amplifying the currents of carrier frequency at intermediate points, and certain other matters such as ringing and the assignment of carrier frequencies will be discussed.

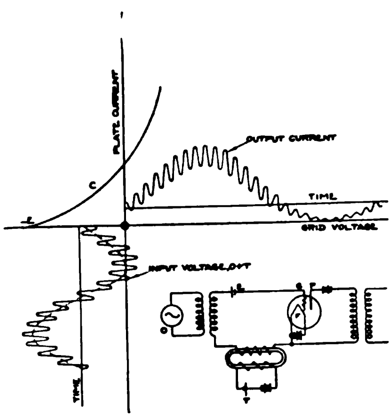

Fig. 10

Fig. 9 shows schematically the circuits involved in a single one-way channel. The source of carrier frequency shown is a vacuum-tube "oscillator." The operation of oscillator circuits in their many forms has been so thoroughly covered in the recent technical literature as not to require detailed discussion here.

Modulation. The process by which the carrier current produced by the oscillator is so combined with the voice currents from the telephone transmitter, that the variations of the latter are impressed upon the former, is known as "modulation," and the tube circuit in which this is accomplished is known as the "modulator."

It will be noted in the circuit shown that the potentials of carrier and voice frequencies are applied in series in the grid circuit of the modulating tube together with a steady voltage from a battery. Owing to the non-linear relation, which exists between the plate current and grid voltage, the output current of the tube is not simply a reproduction of the alternating voltages applied to the grid. In fact, the modulating properties of the tube result from the interactions between applied voltages which this non-linear relation introduces.

The mechanism of this interaction is shown graphically in Fig. 10, which is reproduced above from the paper on Radio Telephony already referred to.[17] It is evident that while the output current includes both the modulating current (here a sinusoid) and the carrier current, the amplitude of the latter varies in accordance with the instantaneous value of the former. Hence, even though the relatively low modulating frequency itself be removed by a selective circuit, its variations are preserved in the wave form of the higher carrier frequency. The form of this modulated carrier wave is shown in Fig. 11. Here curve *A* shows a modulating wave of irregular form representing the voice current, curve *B* the carrier wave, and curve *C* the modulated carrier wave, whose envelope has the form of the modulating wave.

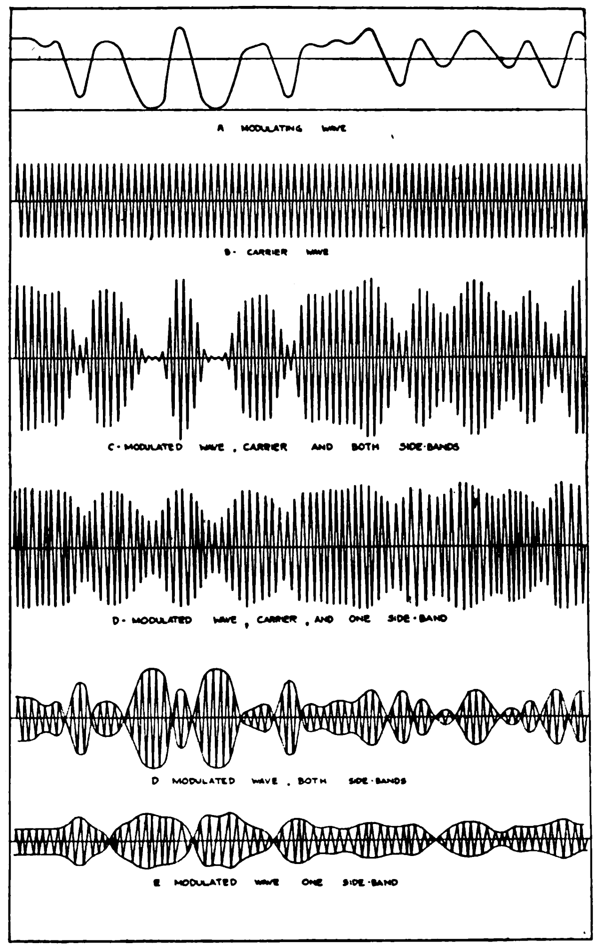

Fig. 11

As it is not at once obvious from an inspection of this modulated carrier wave what must be the frequency characteristics of a circuit which is to transmit it to a distant station, it seems worth while at this point to

17. Craft and Colpitts, loc. cit, page 312.

consider what component frequencies are present in the carrier wave and which of these are essential. The case is exactly analogous to that of attempting to design circuits for ordinary telephone transmission from a consideration of an oscillogram of a voice wave rather than from an analysis of its frequency characteristics. In the case of ordinary telephony, the problem has been solved by analyzing the voice wave into its components of various frequencies and ascertaining which of these frequencies it is essential to preserve and which may safely be neglected. This analysis has been accomplished largely in an experimental way through the use of electrical circuits selective to particular ranges of frequency. As a result of these experiments, it has been determined that speech of satisfactory commercial quality may be secured if the circuit is capable of transmitting all sustained alternating currents whose frequencies lie, let us say, between 200 and 2000 cycles per second. These limits having been determined, the apparatus may then be designed on the basis of its meeting these requirements as to the transmission of sustained single frequencies. The information accumulated at voice frequencies can be applied directly to the solution of the carrier current problem and, incidentally, to radio telephony, provided we know what component frequencies are present in the modulated carrier wave and what relations exist between these components and the component frequencies of the modulating or voice wave. For a complete discussion of the analysis of a modulated wave into its component frequencies, reference may be made to a publication by Carson[18]; and for its application to vacuum-tube operation to van der Bijl[19]. While it is known that a modulated wave can be resolved into a large number of component frequencies, it is necessary to consider here only those components which are directly involved in carrier transmission.

Assume for the moment the complex voice wave to be replaced by a sinusoidal current of a frequency $\frac{q}{2\pi}$ lying somewhere in the voice range. The envelope of the modulated wave will approach closely a sine curve and we may assume the value of the current at any instant to be given by the equation:

$$i = P\,(1 + k \cos q\,t) \cos p\,t.$$

This equation represents a carrier current of frequency $\frac{p}{2\pi}$ whose amplitude varies sinusoidally between the values $(1 - k)\,P$ and $(1 + k)\,P$; k being proportional to the amplitude of the modulating wave. By simple transformation, this may be resolved into its components, giving

$$i = P \cos p\,t + P\,\frac{k}{2}\,[\cos\,(p + q)\,t + \cos\,(p - q)\,t]$$

The first term represents a component of carrier frequency whose amplitude, P, is altogether independent of q and of k; and therefore it has no part in conveying the characteristics of the modulating wave to the distant station. These characteristics are preserved by the remaining two terms, whose frequencies are respectively the sum and difference of the carrier and modulating frequencies, and whose amplitudes are proportional to the product of the carrier and modulating waves.

From this it follows that every component frequency of a modulating voice wave is represented in the corresponding modulated carrier wave by two components, one of which is greater in frequency than the carrier wave by the frequency of the voice component, and the other of which is less by the same amount. We may therefore be certain that all of the essential components of the voice wave will be preserved if those components of the modulated wave are transmitted whose frequencies lie within two frequency bands, one of which extends from the carrier frequency plus 200 upwards to the carrier frequency plus 2000 and the other from the carrier frequency minus 200 down to the carrier frequency minus 2000. These are known as the upper and lower side bands, respectively.

While the above discussion refers more specifically to the use of the vacuum tube as the means for effecting modulation of a carrier current, it should be understood that any device possessing a non-linear current-voltage characteristic will operate more or less effectively as a modulator.

Demodulation. By the term "demodulation" is meant the process of reproducing the original low-frequency modulating wave from the carrier wave upon which it has been impressed. Various methods of accomplishing this result have been known for many years, such as the use of the electrolytic detector of Pupin or of crystal detectors of various forms. All of these operate by virtue of their non-linear current-voltage characteristics. The instrument which has, however, come to be employed almost exclusively for this purpose is the three-element vacuum tube, and the following discussion presupposes its use.

For a concrete example of the use of the vacuum tube as a demodulator, reference may be made to Fig. 9, above, where at the receiving station a modulated wave is shown applied to the input circuit of a vacuum tube. This figure also shows a low-frequency amplifier in the output circuit of the demodulating tube. Because of the bearing of demodulation on the transmission requirements of the system as a whole, we will discuss this matter at some length. Anyone

desiring to pursue the matter still further is referred to the publications[20] already cited under "Modulation."

The operation of the demodulating tube is exactly similar to that of the modulating tube, in that if voltages of two different frequencies are applied to its input circuit, there appears in its output circuit, a complex current wave. When the output current wave is resolved into its components, we find currents identical with the two frequencies which had been applied to the input, one component whose frequency is the sum of the applied frequencies, one component whose frequency is the difference of the applied frequencies, and a large number of harmonics and sum and difference frequencies. The amplitudes of the two currents whose frequencies are the sum and difference of the applied frequencies are proportional to the product of the amplitudes of the applied voltages. When, therefore, the received modulated wave is applied to the demodulating tube, we may determine the frequencies and relative amplitudes of the components of voice frequency in the output circuit of the demodulator by considering the interaction of the various pairs of frequencies in the modulated wave.

Obviously frequencies in the voice range can occur in the demodulator output circuit only as the difference of two components of the modulated wave. If we subtract the carrier frequency from any component of the upper side band, the result is the original speech frequency which produced that component. The interaction of the carrier and the entire upper side band therefore reproduces all the components of the voice wave with their proper relative amplitudes, since the amplitudes of the side band components are proportional to those of the original voice components, and that of the carrier is the same for all of them. The reproduction of the original voice wave also results from the interaction of the carrier with the lower side band.

It is evident that since speech can be reproduced from either side band alone, there is no necessity for transmitting both. Accordingly, the selective circuits to be described later can be so designed as to transmit only one side band. As this effectively halves the range of frequencies assigned to each channel, its great importance is at once obvious. The effect on the wave form of suppressing the upper side band is shown by curve *D*, Fig. 11. It is seen that in addition to the form of the envelope being changed, the times at which the current passes through zero are no longer equally spaced.

It is necessary to consider the interactions between the frequency components of the side band itself, for if, in the case of telephony, the voice wave includes components of more than one frequency, each will be represented by a corresponding component in the side band. The interaction of two of these component frequencies, simultaneously present in the side band, gives rise to a component in the output circuit of the demodulator, the frequency of which is the difference between those of the corresponding two components of the original voice wave. Such currents will have a serious effect on the quality of the reproduced speech, if their amplitude is comparable with that of the reproduced voice currents. The amplitude of this distorting component is proportional to the product of the amplitudes of the two side band components, whereas the amplitude of each of the two components of the desired voice current is proportional to the product of the amplitudes of its corresponding side band component and the carrier. The reproduced voice current can be made large compared with the distorting current only by insuring that the carrier is large compared with every component of the side band. As a result of this, it follows that in order to secure good quality it is necessary that the greater

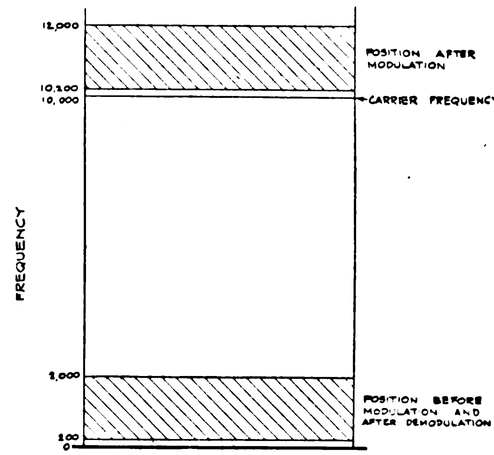

Fig. 12

portion of the energy applied to the demodulator consist of unmodulated carrier frequency.

The behavior of the receiving apparatus—that is, the demodulating tube—to interfering currents, such as may be produced by induction from external sources of electrical energy, so-called static interference, etc., can be directly deduced from the above considerations. With properly designed selective circuits only those line currents whose frequencies lie in the range of the side band being transmitted can reach the demodulator. These can produce noise of voice frequency either by interaction with the currents normally associated with that channel or by interaction with each other. Unless the interfering currents are of greater amplitude than the carrier current, in which case commercial operation is impossible, the noise components of the greatest amplitude result from the interaction of the interfering currents with the carrier current. The noise current in the output circuit therefore bears the same ratio to the reproduced voice current as the interfering line current does to the side band current. It follows,

20. Carson, loc. cit.; van der Bijl, loc. cit.

therefore, that in designing a system it is the side band current, in which are preserved the characteristics of the speech, which must at all points along the line be kept large compared with the extraneous disturbing currents lying within its range of frequency. This consideration has a very important bearing on the electrical design of apparatus operating on the carrier principle, whether dealing with wire or radio transmission.

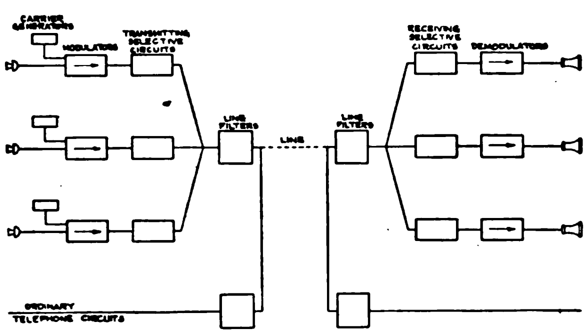

FIG. 13

While our discussion of modulation and demodulation has been made as concise as possible, it is evident from the foregoing that these two are complementary processes. Modulation may be thought of as elevating the band of essential speech frequencies to a position adjacent to the carrier frequency, and demodulation may be regarded as the process of restoring this band to its normal position in the frequency scale. In Fig. 12, the band of voice frequencies is shown, below, in its normal position before modulation, and above, in the position adjacent to the carrier frequency to which it is raised by modulation.

Selection—Electrical Filters. When a number of one-way channels of the type schematically shown in Fig. 9, each employing a different carrier frequency, are operated by superposition on a common line, each channel must be connected with the line through selective circuits which transmit only the range of frequency assigned to that particular channel. Not only must the demodulator assigned to a given channel be prevented from receiving from the line the currents of other channels, but the sending modulator must be prevented from putting onto the line currents of frequencies outside of its assigned band for, as was pointed out in the discussion of modulation, frequencies other than those desired are developed in the output circuit of the modulator, and if these currents were permitted to reach the line, those whose frequencies fell within the transmission band of some other channel would be transmitted to the demodulator of that channel through its receiving selective circuit. The general position of the selective circuits in such a one-way multiplex system is indicated in Fig. 13.

As will be brought out later in the discussion of the behavior of lines with respect to their transmission efficiency at carrier frequencies and with respect to cross-talk between adjacent circuits on a pole line, the most desirable frequency range is rather limited. For this reason, where it is proposed to secure a maximum number of channels simultaneously operating on a given circuit it is necessary to make the frequency interval between the adjacent carrier channels as small as possible. The first limitation to the frequency separation between carrier frequencies is determined by the fact that, as has already been pointed out, the width of the side band must correspond to the voice frequency range; that is, even with ideal apparatus the carrier frequencies must have at least a separation of approximately 2000 cycles per second. The ideal selective circuit which would permit this close spacing of frequencies is one which would transmit efficiently this side band, having a frequency range of 2000 cycles, and would absolutely block off frequencies outside of this band. Because it is not physically possible to secure such ideal circuits, we are obliged to make a greater separation in carrier frequencies than that made necessary by the width of the side band.

The nearest approach to this ideal selective circuit, particularly for carrier operation at moderate frequencies, is secured by the use of what has come to be known as an "electrical filter." This arrangement

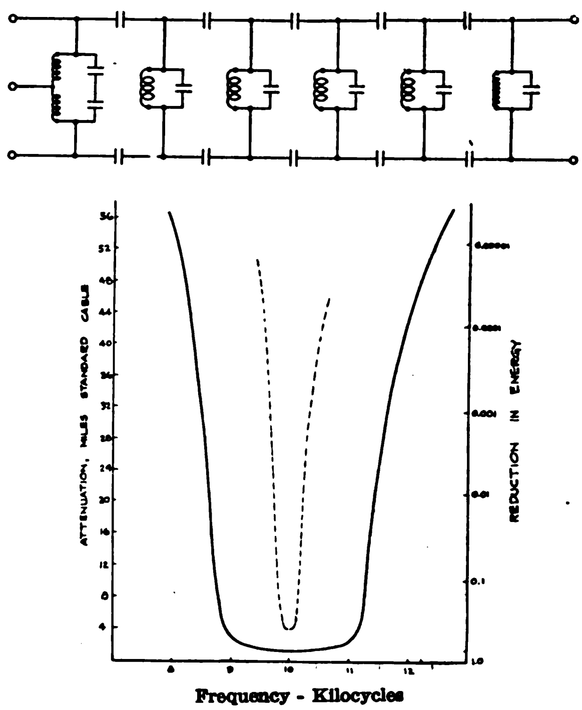

FIG. 14

was invented and thoroughly studied by Dr. G. A. Campbell even before practical carrier operation was made possible by the perfecting of vacuum tubes and the development of their use as oscillators, modulators and demodulators. Campbell's electrical filter is a network composed of inductances and capacities which transmits with a minimum of attenuation currents whose frequencies lie in a predetermined range and attenuates very greatly currents whose frequencies lie

outside that range. While these filters may take a variety of forms to meet special needs, they are all alike in that the currents traverse a succession of meshes or "sections," the attenuating effects of which are cumulative. The discrimination against the frequencies which it is desired to exclude may be increased to any physically practical value by increasing the number of sections.

Fig. 14 shows a type of filter which has been used to great advantage in carrier telephony. As this filter transmits a band of frequencies, it has, for convenience, been termed a "band-pass" filter. The transmission characteristics of this filter are also shown in Fig. 14, where the attenuation introduced into a circuit by the insertion of this filter is plotted against the frequency of the applied current. The attenuation is expressed in miles of standard cable. For the convenience also of those not familiar with this usage there is shown at the right a scale from which may be read for any frequency the fractional reduction of the energy due to transmission through the filter. This particular filter is designed to transmit the upper side band of a carrier of 9000 cycles or the lower side band of a carrier of 11,000 cycles.

At this point it may be instructive to compare the performance of the filter just described with that of a pair of loosely coupled circuits resonant to a frequency in the transmission band of the filter. The attenuation characteristics of such a tuned circuit are shown by the dotted curve in Fig. 14. It is obvious from the attenuations of this circuit in the frequency range of the side band that such a circuit is very poorly adapted to the purposes of carrier telephony.

Referring again to the band-pass filter above described, it is of interest to consider the relation between its attenuation characteristic and the operation of the system. The form of the attenuation curve within its transmission range is important from the standpoint of the quality of the transmission of the carrier channel in which the filter is used. If the attenuation is uniform throughout the frequency range which the filter is designed to pass, the effect is merely the same as that of increasing the length of line by a corresponding amount, and the loss can be compensated for by amplification inserted somewhere in the system. If the attenuation is not the same for all frequencies within the band, as, for example, if it is greater at the edges than at the center of the band, then the difference in transmission equivalent for different components of the side band will introduce a similar distortion into the over-all transmission frequency curve for various voice frequencies, as measured from the modulator input to the demodulator output. Such a distortion would manifest itself by more or less impairment in the quality of the telephone transmission.

Both the magnitude of the attenuation within the frequency band transmitted and the variation with frequency are dependent upon the dissipation of energy in the coils and condensers, as well as upon the choice of their electrical constants, so that the problem of securing filters of desired transmission characteristics has been largely one of obtaining reactance elements of high time-constants and of high accuracy and stability. For the capacities mica condensers are largely used. For the inductances a special core material of finely divided iron has been developed which has made possible toroidal iron-core coils which are superior in time-constant to air-core coils for frequencies up to the highest values used by us. At the same time they are more compact and have less stray field. Transformers having similar iron cores are also used throughout the carrier system. A description of this type of core material and a statement of the results obtained by its use in the telephone plant will form the subject of an engineering paper to be published at an early date.

As has been indicated above, the attenuation of the filter outside of its efficient transmission band, determines the necessary frequency separation between the side bands of adjacent channels and therefore to a large degree also the number of channels which may be operated in a given frequency range. For example, if channel A is operating through the filter shown in Fig. 14, then the frequency band of channel B must be so chosen in the frequency range that the attenuation of the filter in channel A for currents of the frequencies of channel B is at least as great as some value fixed by the cross-talk requirements imposed on the system.

The attenuation outside of the transmission band is practically independent of the resistance of the coils and the dissipation in the condensers, but is determined almost wholly by the arrangement and values of the reactances employed in a section and by the number of sections. Numerous special arrangements have been devised for controlling the form of the attenuation curve and for giving to the filter an impedance best suited to the circuit with which it is connected. It has been found practicable to design filters which permit of operating with an interval of about 1000 cycles between adjacent telephone channels; that is, 3000 cycles between adjacent carrier frequencies.

In addition to separating the various carrier channels from each other it is found convenient from an operating standpoint to separate within the toll offices the carrier frequencies as a group from the frequencies used for ordinary telephony and telegraphy. For this purpose the portion of the line which is used in common is connected with the carrier apparatus through a "high-pass" filter, which transmits all frequencies above a predetermined value (in this case above about 3000 cycles), and suppresses all frequencies below this value (in this case below 3000 cycles). Similarly connection is made with the ordinary telephone and telegraph circuits through a "low-pass" filter, which in this instance passes frequencies

below 3000 cycles and suppresses those above. This combination of carrier line filters, sometimes called a "high-frequency composite set," is shown in Fig. 15, together with the attenuation curves of the two filters. Referring to this figure, it will be seen that currents in the multiplex line divide between the low-pass and high-pass filters shown at the top of the figure. The division is determined at any particular frequency by the relative input impedances of these two branches. Accordingly, the high-pass filter is designed to offer a high input impedance to currents of ordinary telephone frequency, and to have an impedance equal to that of the line for currents within the carrier frequency range. Correspondingly,

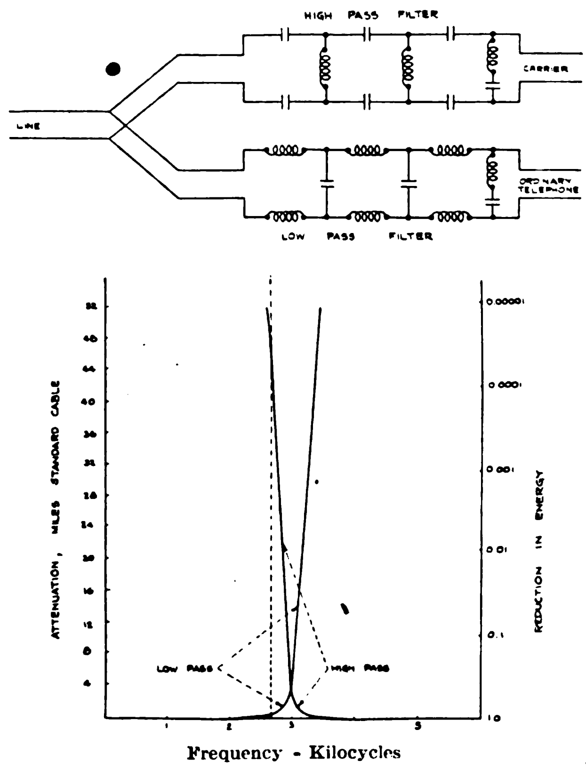

Fig. 15

the low-pass filter is designed to offer a high input impedance to currents of the carrier frequency range and to have an impedance equal to that of the line for currents of ordinary voice frequencies. The attenuation of the high-pass filter is small for carrier frequencies and large for voice frequencies, while the reverse is true for the low-pass filter. Referring to the attenuation curves, which show, as indicated, the attenuation for both the high-pass and the low-pass filters, it is interesting to note how sharp a discrimination is obtained even for frequencies very close to the cut-off points of these filters. For instance, if we select a frequency of 2700 which happens to fall near the upper limit of the normal voice range, it is seen from an inspection of these curves that currents of this frequency are attenuated by about one mile of standard cable when passing through the low-pass filter, but are attenuated by about forty-five miles of standard cable when passing through the high-pass filter. Likewise, a frequency of 3200 near the lower limit of the carrier range is attenuated by less than one mile when passing through the high-pass filter, but is attenuated by about forty-five miles when passing through the low-pass filter. These differences in attenuation correspond roughly to a ratio of energies greater than ten thousand to one.

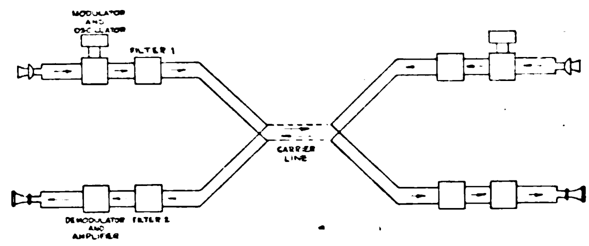

Fig. 16

The location of these line filters in a carrier system is indicated in Fig. 13. A low-pass filter is also used in the output circuit of the demodulator to prevent currents of frequencies higher than the essential voice range from being transmitted to the subscriber.

Arrangements for Two-way Transmission. Thus far the discussion has been limited to transmission in one direction. Provision must be made, however, for associating these one-way channels with the connecting telephone lines so as to permit two-way conversation. In many aspects the problem resembles that encountered in adapting a one-way amplifying element to a two-way talking circuit by means of a telephone repeater. The similarity of the two problems consists not only in the fact that the carrier channel and the

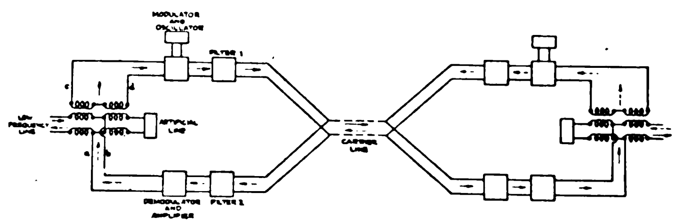

Fig. 17

repeater element are both unilateral or one-way arrangements, but also that both involve amplification, and therefore the same possibilities of "singing" are present in the case of the carrier as in the case of the repeater. The experience, which was gained in the development and engineering of telephone repeaters, has proved of very great value in connection with the development of carrier current systems. For details of the various circuit arrangements, and for a discussion of the fundamentals of the repeater problem, reference may be made to the paper on telephone repeaters mentioned above.[21]

21. Gherardi and Jewett, loc. cit.

In Fig. 16 there is shown schematically an elementary form of two-way carrier telephone circuit. Filters are included in the transmitting and receiving branches, as they are necessary in those branches for multiplex operation. This circuit is entirely operative between two fixed telephone stations. If the same frequency is used for transmitting in both directions, there will obviously be an excess of sidetone in the receiver circuits. It is plain that such a type of circuit has very limited commercial application, and it is shown here merely as a starting point for building up the more generally applicable types.

As in general it is desirable to be able to connect any desired telephone trunk or toll line to the section of line equipped for operation by the carrier current method, it is necessary to adopt for connecting these lines together a circuit of the type which has been studied for many years by telephone engineers, first in connection with subscriber sets, and second in connection with repeater circuits.

Fig. 17 shows schematically one such arrangement. At either terminal of the carrier frequency line, the sending and receiving branches, instead of terminating in a transmitter and receiver, terminate in what are, in effect, conjugate branches of an alternating-current bridge. If the impedance of the artificial line exactly simulates the impedance of the voice frequency line looking outward from the carrier terminal, an electromotive force applied between the points *a* and *b* does not cause any current to flow in the branch *c*-*d* of the carrier current circuit. This represents a condition of zero coupling between the input and output circuits of the carrier system; hence persistent oscillations, *i.e.* singing, cannot be set up. If, however, the balancing network does not accurately simulate the low-frequency line, either of two types of singing may occur. In the circuit arrangement in Fig. 17, if the same frequency is used for transmission in both directions, the type of singing most likely to occur would be local singing at either terminal. This occurs for the reason that in general the amount of energy applied to the two terminals *c* and *d* is largely amplified in the course of passing through the circuit—modulator, filter 1, filter 2, demodulator and amplifier. If the unbalance in the bridge circuit is such that the fraction of this energy which is fed back to the points *c* and *d* is as large as that originally supplied, singing occurs. To avoid this type of singing different carrier frequencies may be chosen for transmission in the two directions. If this is done, local singing cannot be set up, for the reason that filter 2 acts as a block to the return of the output current on itself. End to end singing as distinguished from local singing may, however, occur provided the over-all transmission loss of the line and the terminal apparatus is made less than zero, and provided that there is sufficient unbalance between the artificial lines and the low-frequency lines at both ends. By "transmission loss of less than zero" is meant that the attenuation of the carrier line is more than compensated for by amplification introduced either at the terminal stations or at intermediate repeater stations. However, the accuracy of line balance necessary to prevent end to end singing with carrier circuits such as we have used is very much less than would be required to prevent local singing if the same frequency were used for transmission in both directions. It is interesting to note that in both of these types of singing the sustained oscillations in different portions of the circuit are of different frequencies. Those in the portions used for transmission at voice frequency have some value lying in the voice frequency range. Those in the portions used for transmission at carrier frequencies differ from the carrier frequency associated with that particular channel by the frequency of the oscillations in the low-frequency circuit.

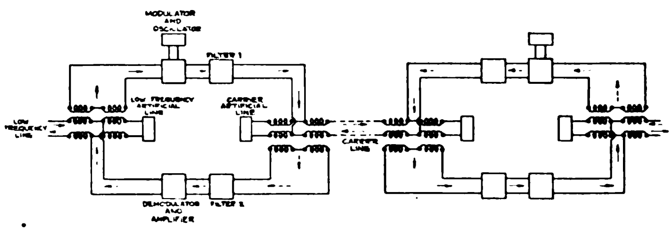

FIG. 18

Whereas, with the circuit shown in Fig. 17, local singing is prevented by the use of different carrier frequencies in the two directions, it is possible to prevent this type of singing without resorting to different frequencies, with the attendant reduction in number of channels, by the use of the arrangement shown in Fig. 18. In this arrangement the energy from the output of the modulator is prevented from reaching the input of its associated demodulator by placing the two in conjugate relation in an alternating-current bridge circuit, of which the carrier frequency line forms one arm, and a balancing network, designed to simulate the line impedance, the other arm.

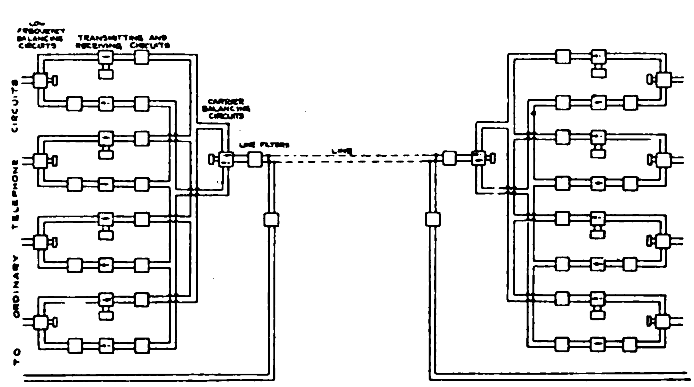

FIG. 19

Both the arrangements shown in Fig. 17 and that

shown in Fig. 18 have been successfully employed for two-way carrier current transmission.

We have already discussed quite fully the selective characteristics of filters and their relation to one-way multiplex operation, and have, in the preceding paragraphs of the present section, pointed out the fundamental principles of two-way operation. In Fig. 19 is shown schematically an arrangement for two-way multiplex operation capable of giving four two-way carrier conversations in addition to the normal telephone facilities. It will be noted that, in this multiplex system, the basic two-way transmission system of Fig. 18 is employed. A similar two-way multiplex system could be built up employing the basic two-way transmission system shown in Fig. 17.

Carrier Suppression. One of the systems which has been developed, particularly for use on long high-grade circuits, involves certain fundamental principles in addition to those already discussed. It will be recalled, that as stated, the proper operation of the demodulator requires that the side-band currents, by

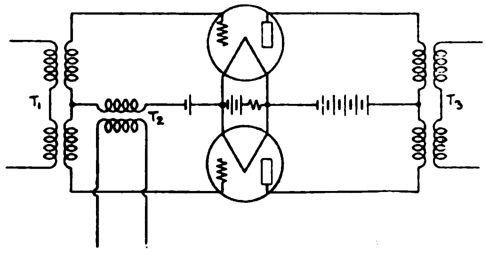

Fig. 20

which are transmitted the characteristics of the speech, be accompanied by a relatively large amount of unmodulated current of carrier frequency. When this carrier current is transmitted from the modulator, it is evident that only a relatively small part of the line current is actually used in conveying the characteristic variations of the voice current. If, therefore, this carrier current is supplied to the demodulator from a local source instead of over the line from the sending station, the amount of line current which it is necessary to transmit per channel is very materially reduced, for then only the relatively small side bands are transmitted. Curve E, Fig. 11, shows the wave form with the carrier suppressed when both side bands are present; and Curve F, Fig. 11, shows the wave form with the carrier suppressed when only one side band is present. In the application of this method, means must be provided for eliminating the carrier current at the sending end and for supplying it to the demodulator from a local source at the receiving end.

Elimination of the carrier frequency at the sending end can be accomplished by what is known as a "balanced modulator," a schematic circuit of which is shown in Fig. 20. In this arrangement two tubes are connected in a manner somewhat similar to the "push-pull" repeater circuit which is described later. The voice frequency potential is applied differentially to the grids of the two tubes by the transformer T_1. The carrier potential is applied through the transformer T_2 to the common portion of the input circuit in such a manner that the carrier frequency potentials of the two grids with respect to the filament are at any instant the same. The resultant carrier frequency currents in the plate circuits of the two tubes are then equal, and the fluxes which they set up in the core of the differential transformer T_3 are equal and opposite; hence no voltage of the frequency of the unmodulated carrier is induced in the output circuit. By a more detailed analysis it can be shown that the side-band currents resulting from the interaction of the carrier and speech-frequency currents are not balanced out but are reproduced in the output circuit. It should be noted that under these conditions, high-frequency current appears in the output circuit only when low-frequency telephone currents are being applied to the input circuit of the modulator.

Harmonic Generator. In order to insure that the carrier current applied to the demodulator in the above system, employing suppressed carrier, is of exactly the same frequency as that used for modulation at the sending end, an arrangement has been devised whereby both of these frequencies are derived from the same source. For this purpose at one terminal of the system a vacuum-tube oscillator generates a frequency somewhat above the voice range—say 5000 cycles. Current of this frequency is applied to the input of another vacuum tube in such a way as to overload it. This "harmonic generator," as it has been termed, is so arranged that the current in its output circuit has a distorted wave-form containing prominent components whose frequencies are exact multiples of the applied frequency. The various harmonics of the base frequency (in this case 10,000, 15,000, 20,000 cycles, etc.) are separated by suitably designed selective circuits and led into individual circuits where they are amplified and made available for use as carrier currents, each in connection with a different channel. At the same time, current of the base frequency from the controlling oscillator, in this case 5000 cycles, is amplified and transmitted over the line to the other terminal. Here it is separated out by a filter, amplified and applied to a second harmonic generator, which produces the same series of carrier frequencies as does the harmonic generator at the controlling station already referred to. These regenerated harmonics may not only be used for demodulating the transmissions received from the controlling terminal, but may also be used in connection with balanced modulators which send in the reverse direction. The demodulators at the controlling station, are supplied with carrier current from the harmonic generator at that terminal.

The suppressed carrier system, besides employing smaller line currents, has two other important advan-

tages. One is the absence of audible beat notes resulting from interaction in the demodulating circuits between the carrier frequency normally present and others which may be present through cross-talk or lack of perfect balance. Where all of the carrier frequencies are generated separately, these combination frequencies may in certain cases give rise to disturbing tones within the voice range. With the harmonic arrangement, on the other hand, the only possible frequencies are differences of the base frequency itself and its harmonics, all of which are above the normal voice range, and accordingly are suppressed by the low-pass filter in the output circuit of the demodulator. As a matter of fact, this harmonic arrangement is practically essential where the same frequency range is used for both directions.

The second advantage arises from the fact that variations in the attenuation of the line, due to weather changes or other causes, have less effect on the transmission equivalent of the system where the carrier frequency itself is not transmitted. This will be clear when it is recalled that the magnitude of the voice current in the output of the demodulator is proportional to the product of the amplitudes of the carrier and side band currents. If, therefore, the change in line attenuation is such as to increase or decrease the side band current by a given ratio, the carrier current when transmitted will in general also be changed in the same ratio, and the resulting voice current will be changed by the square of this ratio. In the suppressed carrier system, on the other hand, while the side band is changed as before, the carrier is increased or decreased—not by the change in attenuation which occurs at the carrier frequency—but by the changes, in general much smaller, which occur at the base frequency, so that the voice current is less affected in this case.

(*To be continued*)

Some Phases of Railroad Telegraph and Telephone Engineering

BY STANLEY RHOADS

Telegraph & Telephone Engineer, New York Central Lines

(*Continued from page* 232 *of JOURNAL for March,* 1921)

Welded Iron Wire Joints

Another step in the improvement of iron wire for telephone circuits is due to oxyacetylene welding of the joints. This has been successfully done on the No. 8 B. W. G. iron wires of the Hocking Valley, Zanesville & Western, and Cleveland, Cincinnati, Chicago and St. Louis Railroads. The resistance of a welded joint is 95 per cent of that of an unspliced wire, whereas the usual soldered joint is 112 per cent of the unspliced wire. Many apparently soldered joints are really not soldered and are about 200 times the resistance of the same length of unspliced wire. The joints are painted with red lead after welding. The work is not excessive in cost and the result is a considerable reduction in resistance and is of a permanent nature. A recent job of welding on the C. C. C. and St. L. Ry., cut the transmission equivalent of the circuit almost in half.

Composite Ringer

The operation of a type B composite ringer was investigated with the oscillograph with the results shown in Fig. 14. Oscillogram No. 193 is the simultaneous record of the outgoing signals when the home station operator rings. Trace No. 1 is the 16-cycle motor-generator ringing current from the operator's keys. Trace No. 3 is the 133-cycle current as produced by the interrupter and delivered to the line, and is flowing to a station 150 miles away over a No. 9 A. W. G. copper phantom circuit, composited.

Oscillogram No. 192 is the record of an incoming signal from the distant office. Trace No. 2 is the wave

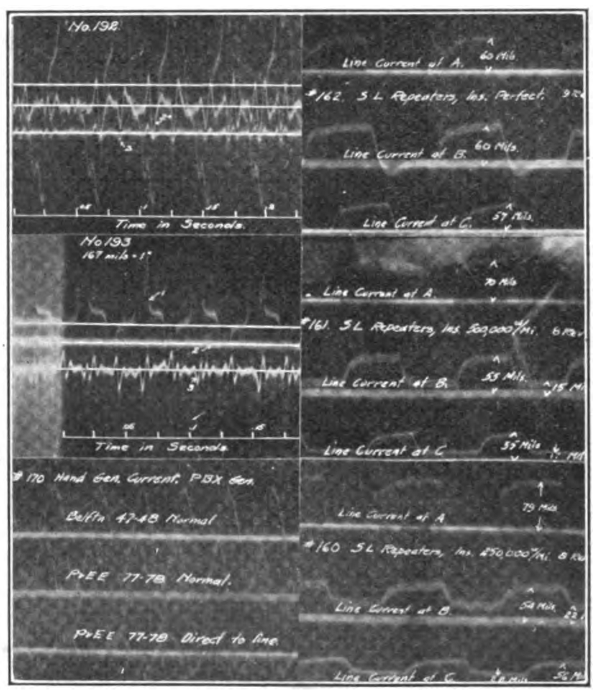

Fig. 14

at a point in series with the high frequency relay and is the deflection calibrated at 50 milliamperes per inch, whereas the No. 1 and No. 3 are 167 milliamperes per

inch as in No. 193. The waves do not resemble sine waves to any noticeable extent but are distorted more like transformer magnetizing current. Oscillogram No. 170 is shown for comparison with hand generator ringing current and presents three separate exposures; the top one on a No. 8 B. W. G. iron wire way-station message selector telephone line, Indianapolis to Bellefontaine; and the middle one is the same generator ringing on a similar circuit, Indianapolis to Springfield, Ohio, through a No. 47-A repeating coil; and the lower trace is on the same line without the repeating coil. The calibration of the oscillograph vibrator elements was not alike in these three exposures.

selector telephone circuits was registered automatically on Veeder counters. The records for several telephone dispatching circuits is given in Table III.

The number of calls per day is interesting. It runs as high as 1223, which is as high as on any existing dispatching circuit, because it is an exceptionally busy line and one man could not do much more on one circuit.

The record of transmitter energy consumption is given in Table IV for several offices in the C. C. C. & St. L. general office building, Indianapolis. The above record gives data for the total of all transmitters in the general office building, and a four-volt, 25-ampere-

Energy Consumption

Several tests have been made to determine the energy consumption of different circuits used in railroad service, particularly those which use primary battery, in order to compare costs of different types of battery. In general, the ampere-hour energy consumption was recorded by copper voltameters and in some cases by watt-hour meters, for periods of 24 hours, of days that were considered average. The number of calls on

hour battery was set up which has since supplied all these transmitters.

The shunt field current of a motor of a dispatcher's selector-circuit motor-generator was found to be 0.3 ampere, which is eight ampere-hours per day, sufficient to charge the 24-ampere-hour battery on the transmitters. The storage battery was placed on continuous charge in this shunt field circuit without either affecting the other detrimentally.

It is quite general practise to feed all local battery transmitters around a railroad general office building from a four-volt or six-volt storage battery of small capacity, placed on continuous charge from the 110-volt d-c. lighting circuit or other available d-c. supply. No cross-talk results, if sufficient copper is used in the busbars from the battery to the distribution point and if the plates of the cells are not too far apart. This continuous charge method requires less supervision than a daily charge method.

It was noted in making the transmitter current tests that new transmitters of a given type use more current than old ones, in some cases twice as much. This is in conflict with the general belief that old trans-

mitters are "packed" and consequently use more current. An explanation for the higher resistance of old transmitters is that the granules lose their many sharp edges and become more nearly round with fewer points of contact with other granules, which increases the resistance of the carbon as a whole with resultant smaller current flow.

Table V shows the record for a selector calling-key battery which was provided for by a twelve-volt, six-ampere-hour storage battery connected in the shunt field of a small motor of a dispatching-circuit motor-generator set.

A test was made on a 48-volt storage battery supplying a Western Electric Co. No. 10, private branch exchange with 45 stations at Beech Grove Shops. The board is operated from 8:00 a. m. to 5:00 p. m., except Sunday, and has six trunks to the main railroad exchange at Indianapolis. The record showed 5.27 ampere-hours per day. The charging rate was based on this at five amperes for eight hours, once per week, with suitable overcharge periods.

A four-ohm sounder used 1.25 ampere-hours in a 24-hour period on two gravity cells. The record for the Chicago Division message operator shows (Table IV), 0.1365 ampere-hour in 24 hours. This transmitter is in almost constant use, sending and receiving messages for the Division Superintendent's office. Therefore, it can be said to fairly represent the average busy local battery telephone on a railroad, consuming more energy than the average way station or block tower. On this record it could be predicted that a 300-ampere-hour set of batteries of equivalent voltage would last 2200 days—or six years. Actually, they would not last quite so long, but are known to last three years and more in this service. At an initial cost for four cells of $8.94 and renewal cost of $5.72 for consumable elements, the cost is less than $2.00 per year, based on three-year life of renewals. Dry cells, three per set, would last about three months and cost about $4.50 per year at 28 cents each. In addition to saving in cost, the caustic soda cells give desirable reliability and require less labor expense. It is standard practise to connect the transmitters of all telephones at any station, and all the telephone selector bells to the same set of caustic soda battery.

Unit Type Power Switchboards

The rapid and uncertain growth of dispatching and message telephone circuits has made it difficult to plan motor-generator sets for battery supply and keep a neat layout of power plant. The C. C. C. & St. L. Railway experienced this trouble and the unit type was adopted. This is shown in Fig. 15. Morse battery supply also has been installed on this plan at Springfield, Ohio, to fit in with the units for the selector lines.

The plan provides one square foot of power panel with the motor and generator line switches, line fuses for both generator and motor, field rheostat, circuit breaker and voltmeter for each machine and in close relation to it. The generator circuits are taken through a jack panel at the left end of the bench, where any machine can be put on any circuit. This type of power installation saves space and puts the control apparatus in close proximity to the motor-generator.

Dry cells have been supplanted by motor-generators and sodium-phosphate-aluminum-iron chemical rectifiers for selector telephone circuits, to a great extent. The motor-generators in the first installations had shunt-wound generators with the inherent characteristic of drop off in voltage with increase of load which was undesirable on selector telephone lines. The load on a dispatcher's circuit consists of series of twenty or thirty short impulses, seldom more than 1500 series per day, which is practically no-load from a power standpoint. The efficiency of a machine therefore, is of less importance than good voltage regulation. The compound generator has been used in all recent installations on the New York Central Lines, separately excited if the motor power supply is direct current.

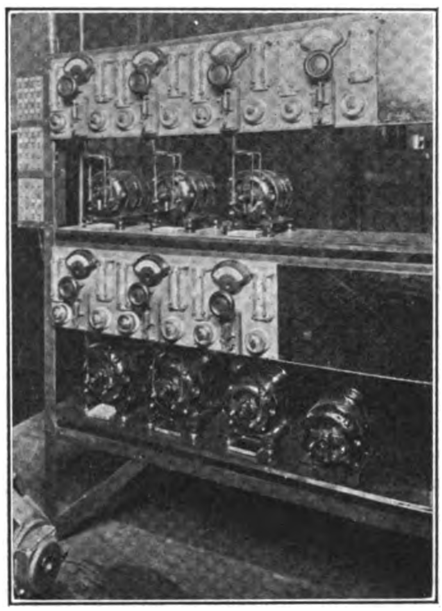

Fig. 15—Unit Type Power Switchboards for Selector Telephone Circuits

Alternating current has been found better suited for the motor supply than direct current, because of

its better regulation. The direct-current power from railroad shops has poor regulation, due to the arc welders, etc., in the shops.

Quick starting motors have been used in some installations, and while fairly successful, are not preferred to the constantly running sets, because of excessive wear of the commutator, due to heavy starting current. Four-bearing motor generators have been found to give better results than two-bearing type. Ring oilers are better than wicks.

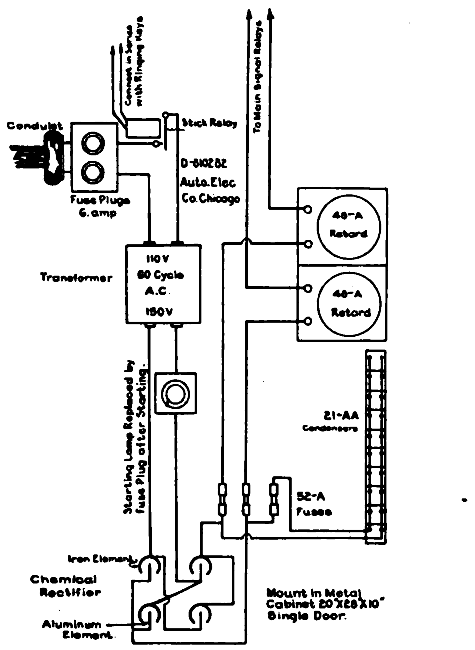

Fig. 16—Wiring of Chemical Rectifier for Selector Telephone Circuits

Chemical Rectifier

The use of the sodium-phosphate chemical rectifier is being extended. The first few sets were purchased but later installations are made up completely by the railroad installers. Four old type sal-ammoniac battery jars are used, containing a solution of commercial sodium phosphate, made up of one pound dissolved equally between the four jars of water, in which is suspended a semi-circular strip of iron separated about one inch from an aluminum strip. Fig. 16 shows the wiring of such an outfit for a dispatching circuit. The condensers and retard coils eliminate the hum of the alternating-current source on the telephone line. The stick relay normally disconnects the rectifier from the a-c. supply between calls on the dispatching line. Fig. 17 shows characteristic curves of such a set. The unmarked curve is the efficiency.

"Single" Morse Current Waves

Perhaps the best known phenomenon to the telegraph fraternity is the sharp snap of the relay when the "single" Morse circuit is closed and opened at the home station, as compared with the comparatively sluggish impulse received in the same relay when a distant station is sending. The comparison is evident in Fig. 18 in oscillogram No. 165 which has two separately made exposures. Trace No. 1 was made at Indianapolis on a single No. 8 B. W. G. iron way wire to Mattoon, Ill., 128 miles long, with forty 120-ohm main line sounder instruments cut in on it with Indianapolis sending. Trace No. 2 is at the same place but with Mattoon sending. The peak of trace No. 1 is the line charging current that gives the snap to the home relay but does not get to the distant station, due to its establishing the electrostatic flux of the line. The No. 163 indicates the current in a

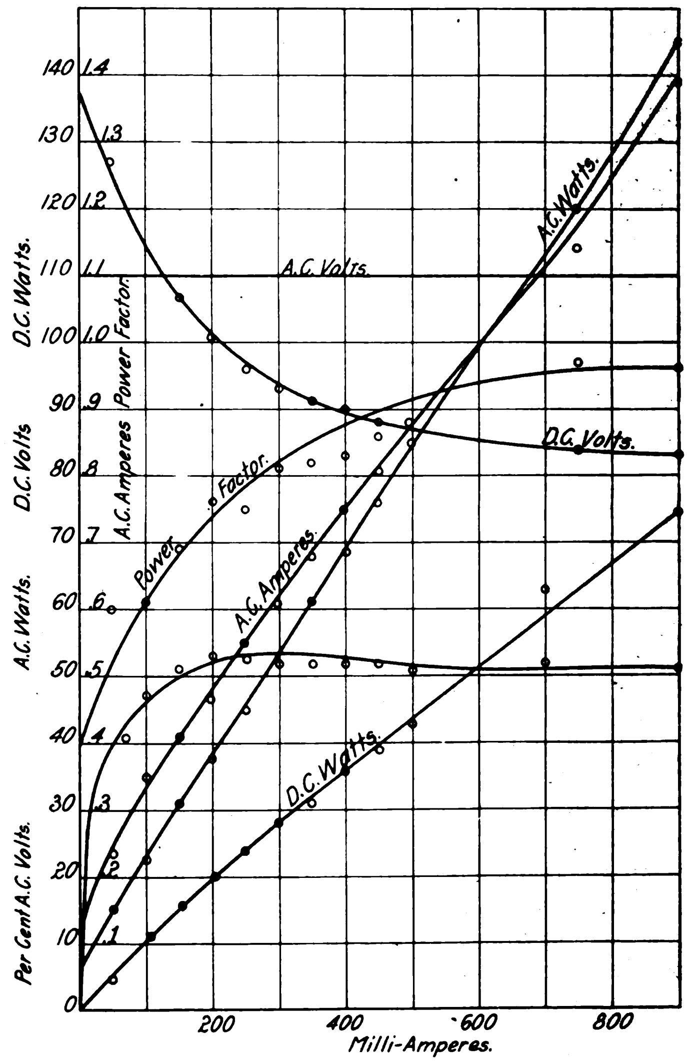

Fig. 17—Characteristic Curves of Chemical Rectifier

block simplex circuit composed of two No. 8 B. W. G. iron wires 140 miles long, Indianapolis to Bellefontaine, Ohio, with 45 Morse relays, 35-ohm, with 79 No. 47-A repeating coils as simplex coils. The upper trace is with Bellefontaine sending and the lower with Indianapolis. The middle trace is on a No. 8 B. W. G.

iron simplexed selector telephone line between the same points.

Telegraph Repeaters

Some tests on telegraph repeaters were made upon an artificial line, shown in Fig. 19, which represented two 150-mile lines with telegraph repeaters connecting them. The line leakage was adjustable to either of three conditions, *viz.*, perfect insulation, ½ megohm per mile and ¼ megohm per mile, by means of switches. Shunt-locking repeaters were used. Oscillogram No. 162 of Fig. 14 records the current simultaneously at three points, with a condition of perfect insulation. The line current at A is the current of the extreme end of one line with the station at that point sending the signals. The current at B is the resultant wave at the other end of the sending line. The line current at C is the resultant current wave that reached the far end of the second line, after being repeated by the station B. This record, compared with No. 165, indicates very close approximation to a real line, as the wave-shape at A is very much like the wave-shape in the upper trace of No. 165, which is under somewhat similar conditions; that is, it is the sending station on a line with several instruments and perfect insulation. The wave-shape at B is much like the wave in the lower trace of No. 165, and both are the received waves at the distant end of a line.

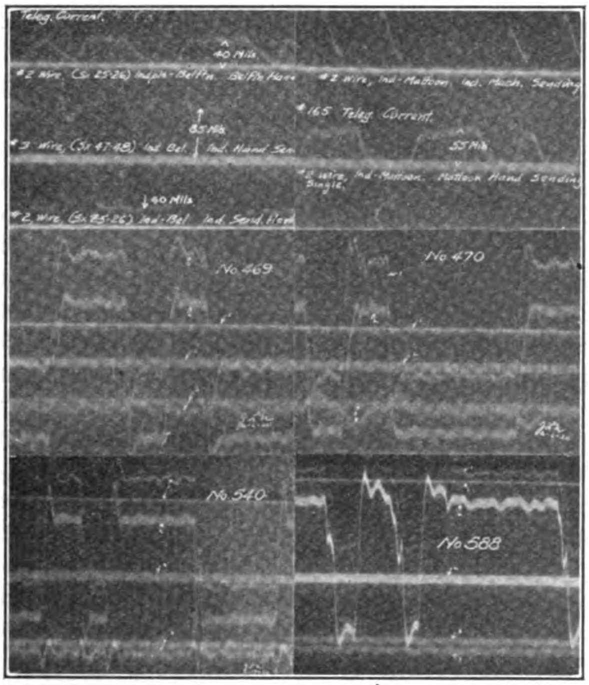

Fig. 18

In No. 162 the time lag between the sending impulse at A and the received impulse at C is considerable. The records represent about one-tenth second to the inch, which indicates that it takes nearly one-twentieth second from the closure of key at A, until the impulse begins at C. The impulses were made with an impulse machine of clockwork with a governor for speed adjustment, and are uniformly 6 per second.

Oscillogram No. 161 is the record at the same points as No. 162, but with line leakage reducing the insulation to one-half megohm per mile. This value of insulation is as low as it is desirable to permit for satisfactory single Morse operation. In this record it is seen that the wave does not become zero at B, when the key opens at A, because the line battery at B causes leakage current to flow. The repeater adjustment is the same in this record as in No. 162. It was lined up for good Morse signals in No. 162 and was not further adjusted. Oscillogram No. 160 is

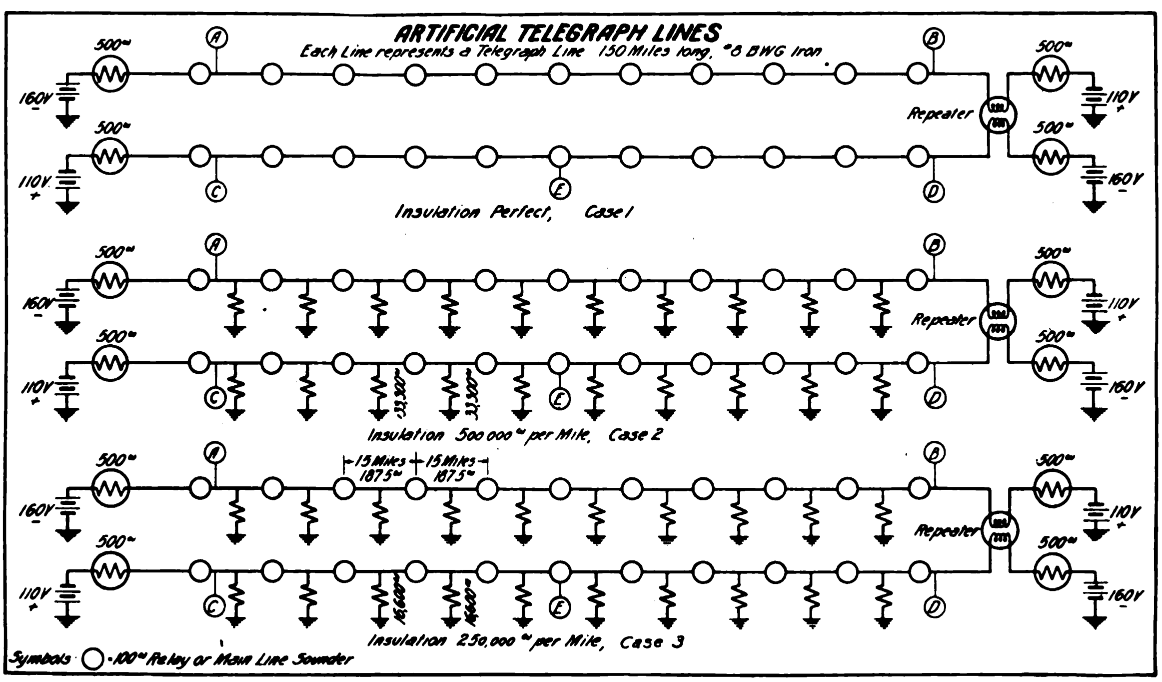

Fig. 19—Artificial Telegraph Lines

the record with the insulation still further reduced to one-quarter megohm per mile, and shows that only little more than half the current was cut off at B by opening the key at A. The tests showed that the signals received at C were unreliable but could be made readable by slight readjustment of the relay at C and without any readjustment of the repeaters at B, which indicates the wide margin of the repeaters. This very low value of insulation is not often found on single wires even in the worst weather if the line is well maintained, but is more frequent on the simplexes with their two wires, which nearly halves the insulation resistance value.

It is not practicable to assume from the above tests that these repeaters will not require readjustment with changing weather conditions. It is seldom that a set of repeaters is adjusted to its very best with perfect line insulation conditions, but it will require attention with change of weather sooner than if perfectly adjusted for good insulation conditions. Table VI gives the current readings at various points in the two artificial lines as actually measured, for different key positions and the three conditions of line insulation resistance.

TABLE VI

E, open at C	0	15	20

Line Insulation

Low insulation apparently is due more to broken and chipped glass insulators than to smoked ones. A perfect insulator measured 40 megohms with a 500-volt megger meter and a similar one measured 10 to 15 megohms with a piece of the outer petticoat of about two inches width knocked off, with the same condition of rain in both tests. An insulator so badly shattered that the tie-wire was holding it together, measured 1 megohm in a drenching rain and when thoroughly water-logged. A mechanically perfect insulator but one very badly crusted by smoke, measured about 40 megohms, after a hard rain, which is about the same value a clean insulator shows. The crust deposited by smoke seems to have high resistance. The megger tests were made on actual lines from line wire to ground after cutting off the line wire about a foot each side of the tie wire. It was found that the resistance from line to pin nearly always equalled the value from line to ground, when the pole and cross-arm were wet. It is important to keep chipped and broken insulators off a line on which the working margin demands good insulation. This is especially important on simplexes, because of the reduced insulation of the two wires in parallel.

Leakage from Wire to Wire

Few references are available relating to the effect of line leakage of one wire on a pole line to a paralleling wire on an adjacent pin. This point came up in a study of a proposal to string a common return wire on an inter-calling selector telephone circuit to take the place of a ground return, installed on the Indianapolis Belt Railroad, semi-circling the city. The telephone selector ground return was affected badly by the city street railway return current, also leakage in wet weather made the ground return so unreliable that some other plan was necessary. The third wire was proposed but it was known that the insulation of the two wires to ground was very low in wet weather and it was feared that the leakage to the third wire would make the system inoperative at such times.

The experiences of telegraph and telephone men were obtained and the general opinion was that the leakage from the two line wires as a simplex to the third wire as a common return would be negligible. The effect was actually found to be less than one-third of the leakage current that existed with the ground return. Assuming that the wires of the telephone pair in wet weather had an insulation resistance of one megohm per mile each, which in parallel was ½ megohm to ground, the third wire with one megohm has its insulation resistance in series with the ½ megohm of the pair, which would make the result theoretically 1½ megohms or three times what it was between the pair and ground.

This type of inter-calling system is limited to very short lines of perhaps a maximum of ten miles, due to the variable operating current of the simplex connection resulting from insulation leakage. The permissible length is 100 per cent greater with a return wire than with a ground return. Circuits 100 to 150 miles have not proved successful.

The leakage from one wire of the pair to the other under ordinary conditions on selector telephone lines has no noticeable effect upon selector operation. The net resistance is the sum of the resistance of each, and the effective voltage to cause leakage current falls from the value of the main battery, usually 200 to 300 volts at one end, to less than 50 volts at the distant end, on most types of selectors, and the total leakage current causes very slight additional voltage drop on the circuits and no apparent effect on the selector operation.

The leakage from one telegraph wire to another can be detected by means of a voltmeter by opening one wire at the distant end, inserting the voltmeter at the home end between the line and ground, and applying voltage to the paralleling wire. The value of the leak

age is so slight that it is seldom observed in the Morse relays of the circuits if worked as single Morse, or on the polar relays if worked as a duplex. The electrostatic induction from paralleling wires, apparently, is noticed more than the leakage.

It has been stated that, in the past, the insulation of railroad circuits was too variable and low to permit of successful loading of open wire lines. Judging from recent tests of insulation, it is now believed to be feasible to load the railroad long-distance lines, which are limited to through service. It would, probably, not be successful on phantoms made up of selector telephone lines.

Single Morse

Both theory and practise indicate that 30 to 35-ohm relays or main line sounders are more desirable than 100 to 150-ohm, for iron wire way-station telegraph circuits, whether single wire or simplex. The actual result has been demonstrated a number of times on the New York Central Lines by changing all the instruments from 100 or 150 ohms to 30 and 35 ohms with marked improvement in the service.

The operating current of telegraph relays, for satisfactory service on railroad way wires, should be something close to the following:

> 30 to 35-ohm relays or main line sounders, 65 milliamperes, closed circuit, to 40 milliamperes on open circuit. The difference between these values gives a margin of 25 milliamperes.
>
> 100 to 150-ohm relays or main line sounders, 40 milliamperes closed circuit, to 25 milliamperes on open circuit. This is a margin of 15 milliamperes.

Formulas for calculating telegraph line current values for the conditions of closed circuit and distant key open, are as follows:

1. For the condition of keys closed:

$$I = \frac{E}{R + \sqrt{\frac{r}{g}}\,\tanh \frac{L}{2}\,\sqrt{r\,g}}$$

2. For the condition of distant key open:

$$I = \frac{E}{R + \sqrt{\frac{r}{g}}\,\coth L\,\sqrt{r\,g}}$$

E is voltage at one terminal, R is terminal resistance of one terminal, r is average line resistance including relays, g is the leakage conductance, mhos per mile, and L is the length of line in miles.

Table VII gives the results of calculations made for the purpose of comparing the current values of single wires and simplexes with 150-ohm relays and 35-ohm relays; with 500,000 and 250,000-ohm line insulation resistance per mile, on No. 8 B. W. G. iron wire.

The two No. 8 B. W. G. iron wires in parallel, in a simplex, have the resistance of the No. 47-A repeating coils added. There are two coils at each intermediate station and one at each end. The intermediate station coils add 21 ohms per station, and the terminals 10.5 ohms, making the average resistance of the circuit 10.4 ohms per mile, which is not a great reduction below the value of a single No. 8 B. W. G. iron wire. The simplex has double the leakage current of a single wire, assuming the same insulation resistance values for both wires. On these simplexes better insulation is desirable than can be permitted on single wires. Comparison of computations Nos. 4 and 6 of the table shows that the margin of a simplex with 500,000-ohm insulation resistance per mile is about the same as a single wire with half that insulation resistance.

TABLE VII

Computed current values, telegraph line 150 miles long with 30 relays comparison of single wire and simplex for three conditions of insulation.

Computation Number	Resistance of relays ohms	Resistance of insulation ohms per mile. per wire	Current—milliamperes: Line closed (a)	Line open distant end (b)	Margin i. e. difference between (a) & (b)	Margin required for satisfactory operation	Dry weather current perfect insulation
	Single No. 8 B. W. G. iron, 12.4 ohms per mile.						
1	150	500,000	52.3	28.9	23.4	15	46.
2	35	500,000	96.5	35.2	61.3	25	91.2
3	150	250,000	58.3	43.3	15.0	15	46.
4	35	250,000	101.5	57.1	44.4	25	91.2
Simplex, No. 8 B.W.G. iron, 10.4 ohms per mile, including simplex coils							
5	150	500,000	60.2	44.1	16.1	15	48.1
6	35	500,000	108.1	58.2	39.9	25	100.
7	150	250,000	70.6	62.3	8.3	15	48.1
8	35	250,000	110	86	24.	25	100.

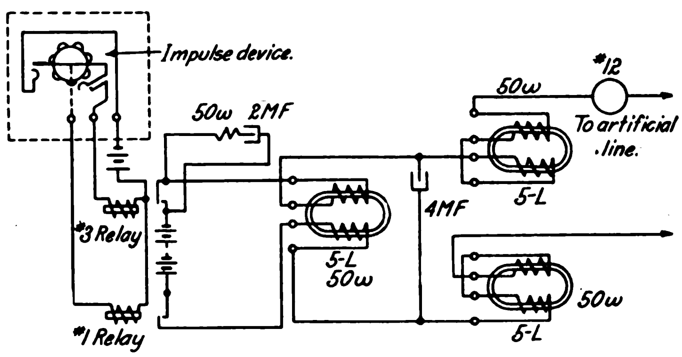

Fig. 20—Signaling Set for Selector Telephone Circuits with 3-5L Coils

The table shows that the 35-ohm relays have better margin than 150-ohm relays under the same conditions of insulation. Comparison of computations Nos. 3 and 4 shows, that the margin is at the limiting value with 150-ohm relays and 250,000-ohm insulation, whereas

the 35-ohm relay margin at 44.4 milliamperes is still. satisfactory. Comparison of computations Nos. 7 and 8 shows similar results on a simplex circuit.

It is found in practise that an entire circuit seldom has a uniform value of insulation resistance in wet weather, because of the variable rainfall rate. It is generally clearing at one end of a division when raining hardest at the other end.

Telephone Selector Current and Voltage Waves

In Fig. 20 retard coils and condenser are indicated in a telephone selector signaling circuit, which are for the purpose of modifying the voltage wave that is impressed on the line so that it will not give listeners on the telephones a disagreeable sound shock. Some investigations were made on an artificial line of Fig. 22 through the signaling equipment of Fig. 20 with the result shown in oscillogram No. 5. The oscillogram No. 127 of Fig. 21 shows the voltage on the battery side of the coils as trace No. S and the simultaneous result on the line side as trace No. 1. The line current is trace No. 2. This shows that the line voltage and current are practically in phase. Considerable delay in the progress of the wave on the line is indicated both at the make and break of the circuit. The condensers in the middle of the retard coils act as a storage battery and assist to prevent the sudden collapse of line voltage when the relay opens. They also cause high initial counter e. m. f. in the coil between them and the battery when the relay closes, thus rounding off and delaying the growth of the line wave. The resultant current wave on an actual line is shown in No. 101. This was taken on a 110-mile dispatching No. 9 A. W. G. copper wire circuit, Indianapolis to Cincinnati, equipped with 32 Sandwich type 4-G selectors, with a main battery of 220 volts. In No. 101, the capacity of the telephone condensers added to that of the line causes a decided oscillatory action at the end of impulses. This is aided by the capacity and retardation in the wave modifying set.

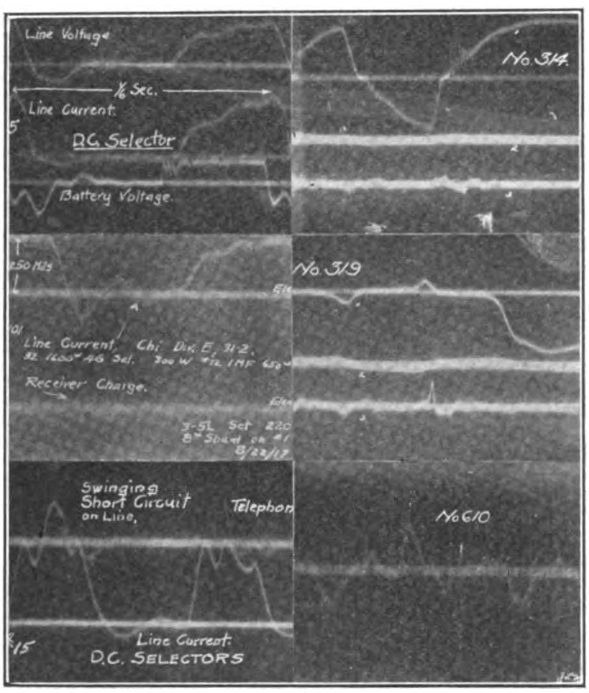

Fig. 21

The cause of the vicious sound in the receiver which occurs due to a swinging short circuit on the line while selector impulses are being sent, is shown in oscillogram No. 15. The upper trace is the telephone condenser wave and the lower is the line current. The short circuit is removed at about the middle of the wave with sudden increase in line voltage with resultant rapid charging of the condenser in the telephone receiver circuit which causes the disagreeable sound shock.

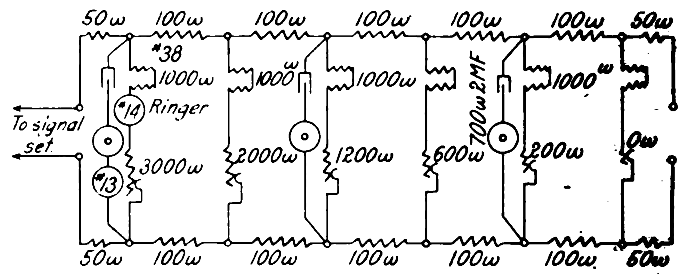

Fig. 22—Artificial Selector Telephone Circuit

The condenser signal sending set of Fig. 23 was recorded in No. 50 and No. 51 of Fig. 24 sending impulses into this artificial selector line, first with 125 volts main charging battery and then with 325 volts. This type of sending circuit is in use to a limited extent on some railroads. The brevity of the line current wave is the outstanding feature of these two records.

The above mentioned Sandwich selectors on the Indianapolis-Cincinnati dispatcher's telephone line were replaced by 32 Western Electric Co. alternating-current selectors, type 60-A, with wiring as shown in Fig. 11; and oscillogram No. 380 shows the current in the battery side of the repeating coils as trace No. 1 and in the line as trace No. 2. This circuit has the condensers removed from the selectors and lumped in the battery side of the repeating coil. The impulses as registered in the line at the sending station on the Indianapolis-Kankakee dispatching telephone circuit, a 140-mile No. 9 A. W. G. copper circuit of 35 No. 60-A alternating-current selectors, is shown in No. 590, in which trace is the line current. These selectors are operated with a condenser in series with each selector and with

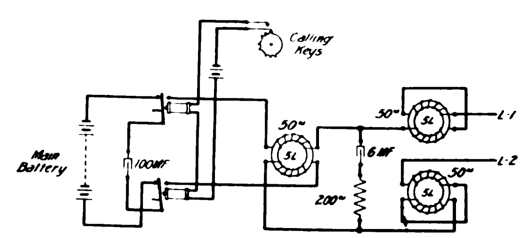

Fig. 23—Condenser Type Signaling Set for Selector Telephone Circuits

the main battery applied directly to the line. It will be noted that the first impulse, which is the closure of the No. 122-E W relay, is but half the amplitude

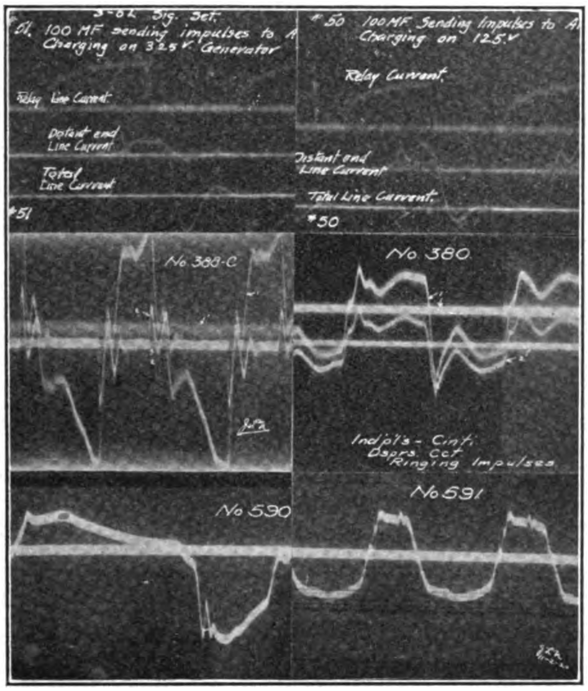

FIG. 24

of the following impulses. Oscillogram No. 591 is the Kankakee circuit line current with the repeating coil signaling set of the Cincinnati circuit sending impulses. The resulting impulses are only half the amplitude of the impulses of the regular signaling set, shown in No. 590. This method is now being experimented with. It is the more desirable plan because with condensers in the bridging selectors the wire chief can make accurate Varley loop Wheatstone bridge measurements for trouble. If the direct battery ringing set of the Kankakee line is put on the Cincinnati circuit which has the condensers removed from the selectors, the result is as shown in No. 388-C, trace No. 1, which is the line current.

Oscillograms No. 319 and No. 314 of Fig. 21 show the comparative impedance of a No. 47-A repeating coil and a D-12984 coil, which is used for the signal sending repeating coil for alternating-current selectors and also as a simplex coil for the "distant" end of such circuits. Trace No. 1 of No. 314 is the current in the No. 47-A coil at the Indianapolis end of an Indianapolis-Bellefontaine No. 9 A. W. G. copper alternating-current selector line 140 miles long, equipped with 45 a-c. selectors not operated through a repeating coil at the sending end, but with the battery applied direct to line at Bellefontaine.

Trace No. 2 is the current through the selector which had two microfarads capacity in series with it. Trace No. 3 is in the phantom telephone branch on this circuit. In No. 319, trace No. 1 is the current through a D-12984 coil. The lobes of this wave on the short impulses are much smaller than on No. 314, indicating much less effect on the line current, while the continuous impulse is somewhat the same shape in both.

No. 610 shows the current through the D-12984

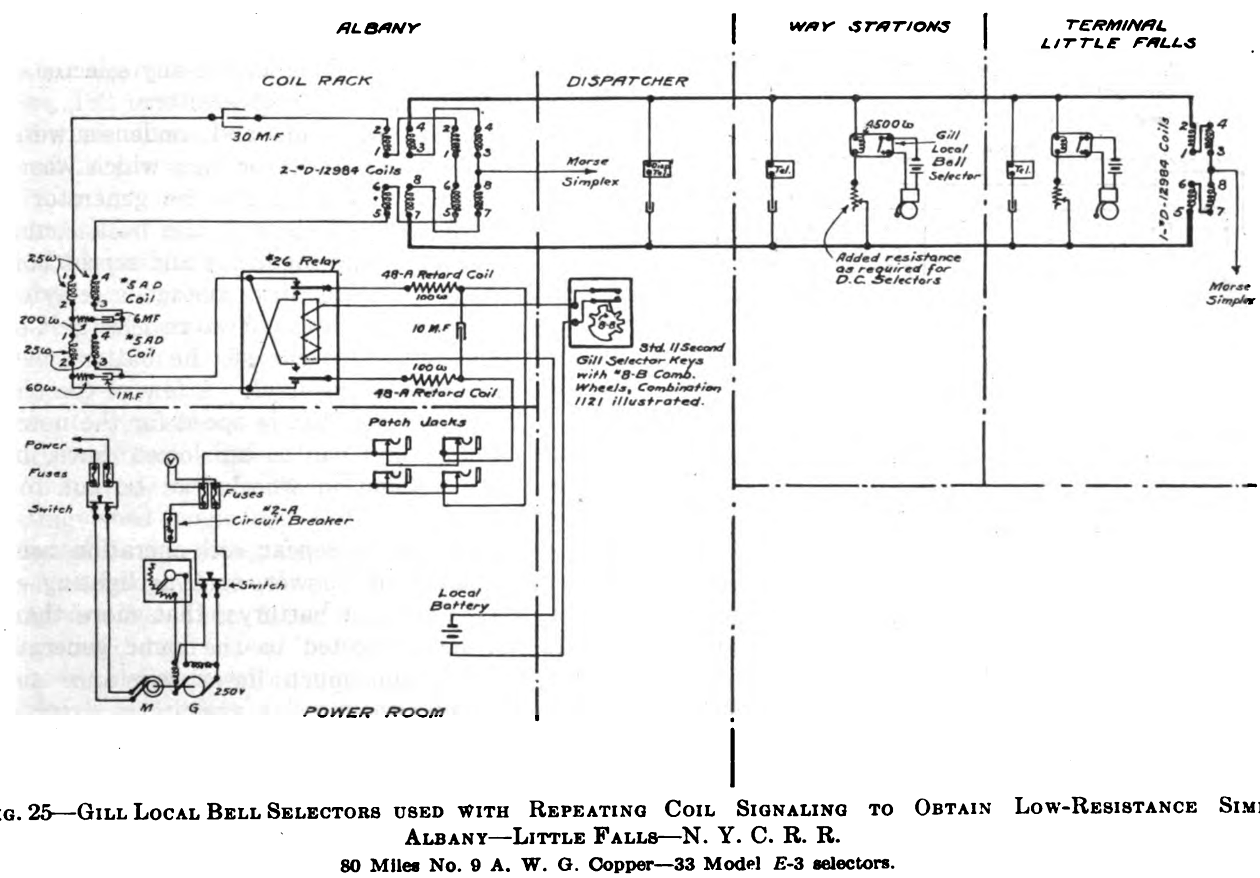

FIG. 25—GILL LOCAL BELL SELECTORS USED WITH REPEATING COIL SIGNALING TO OBTAIN LOW-RESISTANCE SIMPLEX—ALBANY—LITTLE FALLS—N. Y. C. R. R.
80 Miles No. 9 A. W. G. Copper—33 Model *E*-3 selectors.

coil at Indianapolis after the condensers from the selectors had been lumped in a repeating coil type of signal sending set of Fig. 11, at Bellefontaine.

Gill Selectors as A-C. with Low Resistance Simplex

The repeating coil method of operation is applicable to types of impulse selectors which do not require main line battery for ringing the selector bells. The Gill local battery selector, of which a great many are in use, is in this class and is successfully operated through the D-12984 repeating coil, as shown in Fig. 25. The circuit on which this was first used is the Albany-Little Falls dispatching telephone line, which was the first telephone train dispatching circuit in this country; the first one to have selectors, which were the Gill telegraph type, used on a third wire; the first to have selectors on the same wires as the dispatching circuit, which was the series Gill type with selectors in the line at one station in one wire and in the other wire at the next station, alternating first in one wire and then in the other, and operated by simplex current. These series selectors were later replaced by the first "bridging" Gill selectors which are still there and are now converted to "alternating-current" operation, so-called, and are the first circuit of Gill selectors to be so operated.

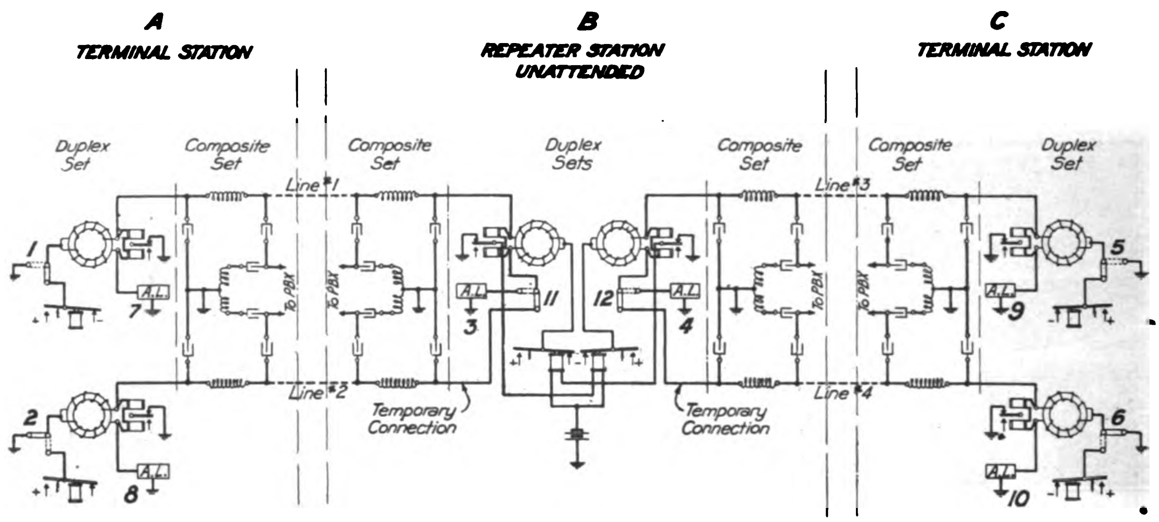

Fig. 26—Unattended Self-Balancing Duplex Applied at Repeater Station

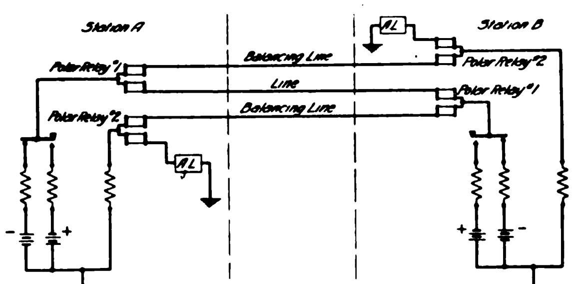

Fig. 27—Theory of a Duplex Circuit Showing Three Wires

The No. 26 relay replaces the ordinary single-contact telegraph relays formerly used; the condensers and repeating coils were installed and new No. 8-B combination wheels were made for the dispatcher's calling keys, and designed so that one impulse is sent when the key contact makes and another when it breaks; otherwise, no change was made in the circuit. The added resistance in series with the selectors was not altered and the current distribution seems to be satisfactory. The circuit is No. 9 A. W. G. copper, 80 miles long with 33 selectors. About one microfarad per selector is enough capacity in the repeating coil circuit to operate the selectors properly. Slightly less main battery is required than before the change was made. The repeating coils reduced the simplex resistance 1000 ohms. It is believed that the method will be found successful on almost any selector circuit now equipped with this type of selector.

The No. 48-A retard coils and condenser were necessary to reduce the generator hum which was heard on the line without them, due to the generator being continuously connected through the back contact of the No. 26 relay, to the condenser and repeat coil. If a key is designed with a third contact, a relay can be inserted, as is used with the Western Electric Co. No. 60-A apparatus case to cut off the battery between operations of the calling keys. A few of the old Gill keys were slightly too fast in speed for the new combination wheels and had to be slowed down, but in future, the combination wheels can be cut to take care of this.

The advantages of repeat coil operation are that grounded sources of power, such as lighting circuit can be used for main battery; that more than one circuit can be connected to the same generator or power supply; and much lower resistance simplex telegraph circuits result.

Polar Duplex and Quadruplex Operation

The standard polar duplex of the Western Union Telegraph Co. is in use on the N. Y. C. Lines, on a

total of 36 circuits and on 9903 miles of circuit. The preferred type is convertible from bridging to differential. The differential is used on composited wires in which the retardation of the Morse leg is sufficient to round off the outgoing wave, and prevent induction trouble. The bridging set is used on simplexes and single wires.

The standard quadruplex is used to a limited extent. As with the duplex, the preferred type is convertible from bridging to differential, and the differential should be limited to use on composited wires.

The action of bridging duplexes and quadruplexes as installed in accordance with the Western Union Telegraph Company's specifications, has been studied to learn their characteristics and better their performance and speed of service, so that such circuits in railroad service can be relied upon to give full output as "double" duplexes and "four-cornered" quadruplexes.

A polar duplex or quadruplex is approximately a three-wire circuit, usually consisting of an actual line and two artificial lines. Actual lines may be substituted for artificial lines as indicated at station B of Fig. 26. Fig. 27 indicates the three wires of a duplex using actual lines in place of artificial lines to balance both No. 1 polar relays. As indicated in Fig. 27 actual or dummy duplex sets are needed at both points designated as No. 2 P. R. With these dummy sets, artificial lines are needed to enable the distant station to get the best balance practicable. Carrying the idea further, it would be possible to use actual lines in place of these artificial lines, also placing dummy sets at the distant ends. In turn, these dummy sets would require balancing lines. Thus, theoretically, the number of balancing lines could be multiplied infinitely. In practise, the balance is found to be practicable with but two balancing lines, and no dummy balancing sets are ordinarily used with artificial line boxes. Hence, the term "approximate" three-wire circuit seems to be a correct designation for a duplex or quadruplex. The artificial line can never exactly balance the real line because there is always one more wire between "home" battery and distant ground in the line side than in the artificial line side, as is readily seen in Fig. 27.

(*To be continued*)

SCHOLARSHIP AND ENGINEERING EMINENCE

A close correspondence between good scholarship in college and eminence in engineering is shown in an investigation made under the auspices of the American Association of Collegiate Registrars by Prof. Raymond Walters of Lehigh University, who presents a report in the current issue of *School and Society*.

It was found that, of 392 distinguished engineers graduated at 75 technical schools, colleges and universities, 182 or 46.4 per cent stood in the highest fifth of their classes scholastically upon graduation, 109 or 27.8 per cent stood in the second highest fifth, 72 or 18.3 per cent in the middle fifth, 14 or 3.6 per cent in the next lowest fifth, and 15 or 3.8 per cent in the lowest fifth.

Figures for a group of 189 alumni of five Eastern engineering schools were somewhat different in the upper classes, the second highest scholastic fifth having the largest percentage. In all groupings of the eminent engineers there were less than 4 per cent in each of the two lowest scholastic fifths.

Of 730 names on the Registrars' Association list of distinguished engineers, practically 80 per cent were found to be collegiate graduates, 16 per cent men of secondary school education and practical training, and less than 5 per cent men who started in college but did not finish.

The arbitrary basis of eminence in this study of a professional group was taken to be the holding of office, membership in important committees and service as representatives of the four national engineering societies of civil, mining, mechanical and electrical engineers, for five years, 1915-1919.

EXPERIMENTAL RADIO MARKET NEWS SERVICE

A daily market report prepared by the U. S. Bureau of Markets is now being sent by radio from the laboratory of the Bureau of Standards at 5 p. m. each day except Sundays and holidays. This report is known as the Daily Radio Marketgram. It is about 500 words long and gives prices and market conditions of fruit and vegetables, grain, dairy products, hay, feed, and seeds, livestock and meats of the principal markets in the nation. Any radio operator within a 200 mile radius of Washington can receive the report. It is transmitted on a wave length of 400 meters at a rate of 15 words per minute. A 2-kw., 500-cycle transmitting set is being used with a non-synchronous rotary spark gap. The report is opened by the general call signal to all stations (Q S T) and the call signal of the Bureau of Standards (W W V).

This service was started as an experiment to determine whether the distribution of market news by radio could be conducted in a satisfactory manner. All radio operators and other persons interested in receiving this information are requested to lend assistance in making the experiments successful. Suggestions for its improvement will be welcomed; It is probable that this experimental service will be extended by the transmission of market news by radio from several other stations including some in the mid-western states. In case this extension involves the substitution of some other station for the Bureau of Standards (W W V) notice to this effect will be broadcasted by radio on several nights from the Bureau's station before its use is discontinued.

Circle Diagram of Polyphase Induction Motors

BY J. K. KOSTKO

Wagner Electric Mfg. Co.

In submitting this article the writer wishes to disclaim any intention of making a contribution to the theory of a subject so thoroughly studied as the circle diagram of polyphase induction motors. But while the theory of the circle diagram may be considered as a closed chapter, its practical application, as a method of determining the characteristics of motors from test data, has not kept pace with the theory; at least, all constructions known to the writer are either not simple enough for practical use, or are based on assumptions which hold good only within rather vaguely defined limits; in particular, there is no simple and accurate method applicable to small and fractional horse power motors for which the approximate diagram is entirely inadequate.

The method given in the article is applicable to all cases, but has been primarily developed and used in connection with small motors, its characteristic feature being that the smaller the motor, the easier the construction of the diagram. It is thought that in view of the enormous development of the small motor industry this feature may be of sufficient interest to justify an addition to the literature of the circle diagram.

THE circle diagram of the induction motor is usually based either on the approximate equivalent circuit of Fig. 1 or on the exact circuit of Fig. 2. The object of this article is to make a brief study of the circuit of Fig. 3, intermediate between Figs. 1 and 2,

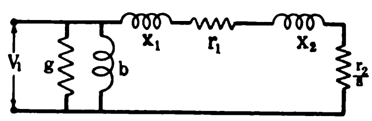

FIG. 1

and physically equivalent to a motor without core loss connected in multiple with a core loss circuit g; it will be shown that this circuit combines the advantages of Figs. 1 and 2; its circle diagram is practically as accurate as the exact locus of Fig. 2[1], and in point of simplicity of construction from test data it comes

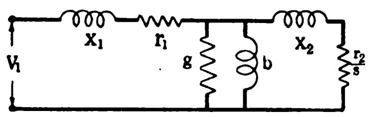

FIG. 2

fairly close to that of Fig. 1, especially for small motors, *i. e.*, precisely where the approximate diagram of Fig. 1 is not applicable.

For the study of the current locus of Fig. 3 it is convenient to retain the transformer analogy of the motor by replacing the susceptance b by a transformer T,

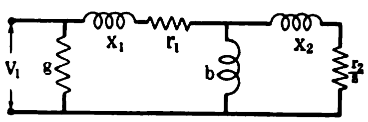

FIG. 3

Fig. 4, without leakage and of 1 to 1 ratio; each winding of this transformer will have a reactance $X = 1/b$.

Let $O\,I$, Fig. 5, be the current I_1' in the branch $x_1 - r_1 - X$; the applied voltage V_1' is the sum of the ohmic drop $r_1 I_1' = O\,R'$, the counter e. m. f. of leakage reactance $x_1 I_1' = R'\,S'$, the counter e. m. f. of primary reactance of T, $XI'_1 = S'\,C'$, and the e. m. f. $X\,I_2' = C'\,E'$ induced in the primary of T by the secondary current I_2'. $E'\,O$ represents the applied voltage V_1'. I_2' is induced in a circuit of resistance r_2/s and reactance $X + x_2$ by the e. m. f. $X\,I_1' = S'\,C'$ due to the primary current, and the phase relation of e. m. fs.

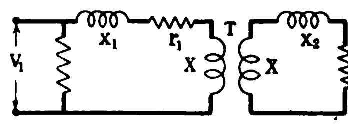

FIG. 4

$S'\,C'$ and $C'\,E'$ results from the vector diagram of the secondary circuit $S'\,C'\,E'\,U'\,S'$ in which $S'\,C' = X\,I_1'$, $S'\,U' = r_2/s \times I_2'$, $U'\,C' = (X + x_2)\,I_2'$, and $E'\,C' = X\,I_2'$.

If the branch $x_1 - r_1 - X$ is supplied with constant current I_1', $S'\,C' = X\,I_1'$ remains constant, and the

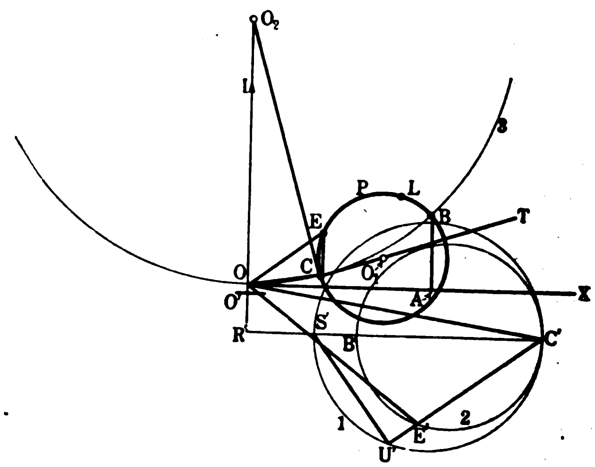

FIG. 5

point U' moves on a circle 1 described on $S'\,C'$ as diameter. Since $C'\,E' = C'\,U' \times \dfrac{X}{X + x_2} = C'\,U'$ $\times$ constant, the point E' moves on a circle 2 described on $B'\,C' = S'\,C' \times \dfrac{X}{X + x_2}$ as diameter; this circle is the

1. See Note 1 in appendix.

locus of applied voltage at constant current. At C', $(X + x_2) I_2' = 0$, *i. e.*, $I_2' = 0$; and, since $r_2/s \times I_2' = S' C' \neq 0$, the slip must be zero; C' is the no-load point. At B' the point U' coincides with S' and

$$\frac{r_2}{s} \times I_2' = S' U' = 0; \text{ but } I_2' = \frac{B' C'}{X} \neq 0,$$

therefore $s = \infty$. At B' and C' the resultant e. m. f. $S' E'$ is at right angles to the current $O I$, *i. e.*, at these points the torque is zero.

From locus 2 of applied voltage at constant current I_1' the current locus at constant voltage V_1 is derived by inversion with O as center and $V_1 I_1'$ as constant of inversion, followed by substitution for the inverse figure of its image with respect to $O Y$[2]; this transforms the circle 2 into the final circular locus P. This locus of the motor branch $x_1 - r_1 - X$ will obviously become the locus of the entire circuit of Fig. 3 if the origin is moved to a point O' such that $O' O$ = current in the core loss branch g.

Let B and C on the circle P correspond to B' and C' on the circle 2. Since the circle 2 is normal at B' and C' to the line $R' C'$, the circle P is normal at B and C to the inverse of $R' C'$; the latter is a circle 3 of diameter

$$\text{equal to } \frac{I_1' V_1}{O R'} = \frac{V_1}{r_1}, \text{ having its center } O_2 \text{ on } O I.$$

This geometrical relation shows that *the center of O_1 of the locus P lies on the tangent $C T$ to the circle 3, i. e., on the perpendicular $C T$ to the segment $C O_2 = V_1/2r_1$ passing through the zero-torque point C.*

Construction of the Circle Diagram from Test Data

The required tests are: (1) Primary resistance r_1[3], (2) No-load test, (3) Locked test. Due to the friction torque the no-load point is slightly above the true zero-torque point C. This test point can be used in a preliminary diagram; if the friction torque is known, the zero-torque point can be approximately determined from this diagram and used for the construction of the final locus; but this refinement is seldom, if ever, necessary; usually the no-load point can be considered as the zero-torque point C.[4]

In Fig. 6 let $O' Y$ be the direction of the applied voltage and L and C the locked and the no-load points. The current locus passes through C and L, and its center is found, as explained above, by the following rule: *on $O' Y$ locate a point O_2 such that*

$$C O_2 = \frac{V_1}{2 r_1};$$

the center O_1 of the locus P is the intersection of the perpendicular bisector of $C L$ with the perpendicular $C T$ to $C O_2$. The circle 3 cuts the locus at B, where $s = \infty$, and the axis $O' Y$ at O, which corresponds to the point O of Fig. 5, *i. e.* it is the origin of currents in the branch $x_1 - r_1 - X$; $O' O$ is the core loss component; $O J$ (with $C J \perp O Y$) covers the ohmic loss of the no-load current $O C$ in the branch $x_1 - r_1 - X$, *i. e.* $V_1 \times O J = r_1 \times O C^2$; this can also be seen from the geometrical relation

$$O C^2 = (\text{diam. of } 3) \times O J = \frac{V_1}{r_1} \times O J.$$

In small motors the resistance r_1 is relatively so great that the radius

$$\frac{V_1}{2 r_1}$$

of the circle 3 is not excessive, and the locus can be constructed with an ordinary compass. If

$$\frac{V_1}{2 r_1}$$

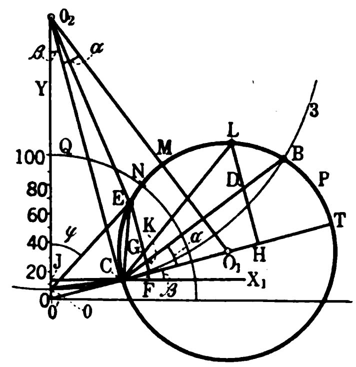

Fig. 6

becomes so great that the center of 3 lies at an inconveniently great distance, it is usually an indication that the angle of tilt of the locus is very small, and the approximate diagram of Fig. 1 is sufficiently accurate. In all cases the angle of tilt β and the points B and O can be found by calculation as follows:

Let I_0 be the no-load current and $J C$ its reactive component; since $O_2 C$ is perpendicular to $C T$, the angle $J O_2 C = \beta$, and the triangle $J O_2 C$ gives

$$\sin \beta = \frac{J C}{C O_2} = \frac{2 r_1 \times J C}{V_1} = \sim \frac{2 r_1 \times I_0}{V_1} \qquad (1)$$

The angle of tilt is thus nearly proportional to r_1; a good agreement between the locus and the brake test points can be expected only if r_1 is measured at the same temperature of the motor as during the brake test.

After the locus P has been constructed, its radius R can be measured and the point B ($s = \infty$) determined by calculating the angle $T C B = O_1 O_2 C = \alpha$ in the triangle $O_1 O_2 C$ which gives

2. See Arnold, Wechselstromtechnik, Vol. 1, 2nd ed., p. 70.

3. It is hardly necessary to add that the knowledge of the stator connection (star or delta) is not essential; if V_1 and r_1 are calculated as for the star connection, all conclusions will hold good, and the currents in the diagram will be line currents, regardless of the connection of the stator.

4. Note 4.

$$\tan \alpha = \frac{C\,O_1}{C\,O_2} = \frac{2 r_1 \times R}{V_1} \qquad (2)$$

The angle $O\,C\,J$ is measured by one-half of the arc $O\,C$ and is, therefore, equal to

$$\frac{\angle\, J\,O_2\,C}{2} = \frac{\beta}{2}\,;$$

i. e. the point O is the intersection of $O'\,Y$ with the bisector of the angle $T\,C\,X_1$; this point may be located by the eye.

Motor Constants and Performance Data Derived from the Diagram

Reactances x_1 and x_2. A circle diagram gives these elements only in combination; their sum x_s is found as follows: at B the slip

$$s = \infty, \frac{r_2}{s} = O,$$

and the motor branch of Fig. 3 is equivalent to the resistance r_1 in series with the reactance

$$x_1 + \frac{X\,x_2}{X + x_2} = \frac{x_1 + x_2 + x_1\,x_2\,/\,X}{1 + x_2\,/\,X}.$$

If $\varphi\infty$ is the angle of lag between the voltage and the current at B, then

$$\tan \varphi\,\infty = \frac{x_1 + x_2 + x_1\,x_2\,/\,X}{1 + x_2\,/\,X} \div r_1 = \frac{O\,A}{A\,B}$$

(Fig. 5); therefore

$$x_s = x_1 + x_2 = \sim r_1 \times \frac{O\,A}{A\,B} \qquad (3)$$

because the rejected terms are small relative to x_s. If greater accuracy is desired, this value of x_s may be corrected as shown below (form. 5).

Reactance $X = \frac{1}{b}$. At C the slip $s = O$, the secondary of T in Fig. 4 is open and the current in the branch $x_1 - r_1 - X$ is

$$O\,C = \frac{V_1}{\sqrt{r_1^2 + (X + x_1)^2}}$$

$$= \sim \frac{V_1}{X + x_1}\,;$$

hence

$$X = \frac{V_1}{O\,C} - x_1 \qquad (4)$$

Since x_1 is small relative to X, an appreciable error in the estimation of x_1 in this expression has a negligible influence on X; it can be assumed with a fair degree of accuracy that x_1 = 60 per cent of x_s with a wound rotor, and x_1 = 70 per cent of x_s with a squirrel-cage rotor.

This value of X can be used for correcting x_s as follows: let σ be the preliminary value of $\frac{x_s}{X}$ (analogous to the leakage coefficient of the approximate circle diagram); then

$$\frac{x_1 + x_2 + x_1\,x_2\,/\,X}{1 + x_2\,/\,X}$$

$$= x_s \left[\frac{1 + \sigma \times x_1/x_s \times x_2/x_s}{1 + \sigma \times x_2/x_s} \right] = r_1 \times \frac{O\,A}{A\,B}\,;$$

hence

$$x_s = r_1 \times \frac{O\,A}{A\,B} \times \frac{1}{M} \qquad (5)$$

where M is the expression in [ ]. With the preliminary value of σ M can be calculated for various values of

$$\frac{x_1}{x_s} \text{ and } \frac{x_2}{x_s} = 1 = \frac{x_1}{x_s}\,;$$

the corrected value of x_s is then found from (5). Fig. 7 gives M for the range of values of σ and $\frac{x_1}{x_s}$ occurring in practise; it shows that within normal limits of σ the correction is small and not much influenced by the arbitrary choice of $\frac{x_1}{x_s}$.

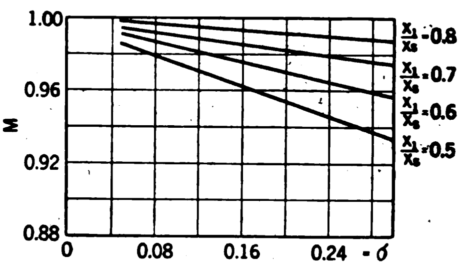

Fig. 7

Secondary Current I_2. In Fig. 5 the triangles $O\,C'\,E'$ and $O\,C\,E$ are similar because $\angle\, C'\,O\,E' = \angle\, C\,O\,E$ and $O\,E' \times O\,E$ = constant of inversion $= O\,C' \times O\,C$, *i. e.* $O\,E / O\,C = O\,C' / O\,E'$; therefore,

$$O\,E = C\,E \times \frac{O\,C'}{C'\,E'}\,;$$

but $O\,E = I_1$; $C'\,E' = X I_2'$;
$O\,C' = \sqrt{O\,R'^2 + R'\,C'^2} = I_1' \sqrt{r_1^2 + (X + x_1)^2}$, therefore,

$$I_1 = C\,E \times \frac{\sqrt{r_1^2 + (X + x_1)^2}}{X} \times \frac{I_1'}{I_2'}\,;$$

since

$$I_1 \times \frac{I_2'}{I_1'} = I_2,$$

this gives

$$\textit{Secondary current } I_2 = C\,E \times \frac{\sqrt{r_1^2 + (X + x_1)^2}}{X}$$

$$= \sim C\,E \times \frac{X + x_1}{X} \qquad (6)$$

i. e. the secondary current is proportional to the segment $C\,E$; the coefficient of proportionality

$$k = \frac{\sqrt{r_1^2 + (X + x_1)^2}}{X}$$

has a physical meaning: at no-load (open secondary in Fig. 4), the branch $x_1 - r_1 - X$ gives $V_1 = I_0 \sqrt{r_1^2 + (X + x_1)^2}$, and the *e. m. f.* due to the revolving field $= I_0 X$; therefore

$$\textit{Secondary current } I_2 = C\,E \times k = C\,E \times \frac{\text{applied voltage}}{\text{counter e. m. f. at no-load}} \qquad (6a)$$

Torque. In Fig. 6 let φ be the angle $E\,O\,O_2$; the input to the motor branch $x_1 - r_1 - X$ is $V_1 I_1 \cos \varphi$, and the input to the rotor-torque in synchronous watts is $V_1 I_1 \cos \varphi - r_1 I_1^2$; in the triangle $E\,O\,O_2$, $O\,O_2^2 - O_2 E^2 = 2 \times O\,O_2 \times O\,E \cos \varphi - O\,E^2$; but

$$O\,O_2 = \frac{V_1}{2\,r_1}\,; \; O\,E = I_1,$$

therefore,

$$O\,O_2^2 - O_2 E^2 = \frac{V_1 I_1 \cos \phi}{r_1} - I_1^2\,;$$

hence

$$\textit{Torque (per phase) in synchronous watts} = r_1 (O\,O_2^2 - O_2 E^2) \qquad (7)$$

Since

$$O\,O_2 = \frac{V_1}{2\,r_1} = \text{constant},$$

this shows that with a stator of given resistance the torque is the same at all points for which $O_2 E$ is constant, *i. e.* at all points of a circle concentric with the circle 3; the latter is the zero-torque circle. The torque is maximum where $O_2 E$ is minimum, at the intersection M of the locus with the perpendicular bisector of $C\,B$.

Let $E\,F$ be perpendicular to $C\,T$. In the triangle $O_2 E\,C$, $C\,O_2^2 - O_2 E^2 = 2\,C\,O_2 \times F\,E - C\,E^2$; if R is the radius of P, then $C\,E^2 = C\,F \times 2\,R$; but the similar triangles $O_2 C\,O_1$ and $C\,K\,F$ give $C\,F \times R = C\,O_2 \times F\,K$, therefore, $C\,E^2 = 2\,C\,O_2 \times F\,K$; substituting $C\,O_2^2 - O_2 E^2 = 2\,C\,O_2 \times F\,E - 2\,C\,O_2$

$$\times F\,K = 2\,C\,O_2 \times K\,E = \frac{V_1}{r_1} \times K\,E,$$

hence

$$r_1 (C\,O_2^2 - O_2 E^2) = \textit{Torque in synchronous watts} = V_1 \times K\,E \qquad (7a)$$

i. e. the segment $K\,E$ is equal to the component supplying the torque.

Secondary Output. The rotor copper loss is proportional to $C\,E^2$; but $C\,E^2 = C\,F \times 2\,R$, and $C\,F$ is proportional to $K\,G$ because the lines $C\,L$ and $C\,B$ are fixed; the rotor copper loss is, thus, proportional to $K\,G$, and the coefficient of proportionality is found by observing that at L the rotor copper loss is equal to the entire rotor input $V_1 \times D\,L$, which shows that the coefficient of proportionality is V_1, *i. e.* the segment $K\,G$ in amperes is equal to the component covering the rotor loss:

$$\textit{Secondary copper loss} = V_1 \times K\,G \qquad (8)$$

Equations (**7a**) and (**8**) give

$$\textit{Secondary output} = V_1 \times K\,E - V_1 \times K\,G = V_1 \times G\,E \qquad (9)$$

Thus, the components corresponding to the rotor input, output and loss can be taken from the diagram directly in amperes, *but the representative segments must be taken in the direction perpendicular to the diameter of the current locus, and not in the direction parallel to the direction of the applied voltage.*[5] The output is maximum at the intersection N of the locus with the perpendicular bisector of $C\,L$.

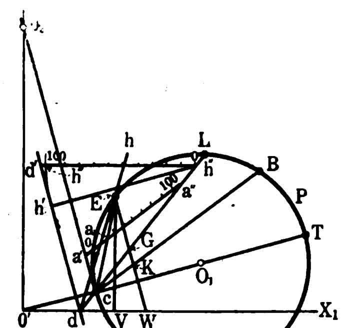

FIG. 8

At L the rotor copper loss $= r_2 \times (C\,L \times k)^2 = V_1 \times D\,L$; hence

$$\textit{Secondary resistance } r_2 = V_1 \times \frac{D\,L}{C\,L^2} \times \frac{1}{k^2} \qquad (10)$$

Determination of the Locked Point Corresponding to a given value of r_2. This problem arises, for instance, when it is desired to improve the performance by changing the size or material of rotor bars or end rings. Formula (**10**) gives: $D\,L/C\,L^2 = k^2 r_2/V_1$; in Fig. 6 $C\,L^2 = C\,T \times C\,H = 2\,R \times C\,H$, therefore, substituting, $D\,L/C\,H = 2\,R\,k^2 r_2/V_1$; but [formula (**2**)]

$$D\,H/C\,H = \tan \alpha = \frac{2\,r_1 R}{V_1}\,;$$

hence adding, $(D\,L + D\,H)/C\,H = L\,H/C\,H$

$$= \tan \angle\, L\,C\,H = \frac{2\,R}{V_1} \times (r_1 + k^2 r_2),$$

which determines the locked point L.

Slip. The slip is the ratio of the rotor copper loss to the total rotor input,

5. See Note 3.

$$s = \frac{K\,G}{K\,E}.$$

As $K\,G$ cannot be read accurately, it is preferable to write

$$\textit{Slip}\ s = \frac{D\,L}{K\,E} \times \frac{K\,G}{D\,L} = \frac{D\,L}{K\,E} \times \frac{C\,F}{C\,H}$$

$$= \frac{D\,L}{K\,E} \times \left(\frac{C\,E}{C\,L}\right)^2 \tag{11}$$

Graphical Determination of the Slip. In Fig. 8 draw $a'\,a''$ parallel to $C\,B$ at any convenient distance. The similar triangles $G\,K\,C$ and $C\,a'\,a''$ give (a) $K\,G/C\,K = C\,a'/a'\,a''$; the similar triangles $E\,K\,C$ and $C\,a'\,a$ give (b) $K\,E/C\,K = C\,a'/a'\,a$; dividing (a) by (b):

$$\frac{K\,G}{K\,E} = \textit{Slip} = \frac{a'\,a}{a'\,a''} \tag{12}$$

i. e. if $a'\,a''$ is divided in 100 equal parts, the per cent slip is $a'\,a$.

Graphical Determination of the Efficiency. It is usually preferable to calculate the efficiency by the separate loss method, but the following graphical construction can also be used. In Fig. 8 produce $L\,C$ to d and draw (1) $d\,d'$ parallel to $C\,O_2$, (2) $h'\,h''$ parallel to $C\,T$ at any convenient distance, (3) $h''\,d'$ parallel to $O'\,X'$. The triangles $d\,G\,W$ and $d\,d'\,h''$ are similar hence (a) $G\,W/d\,W = d\,d'/d'h''$. The similar triangles $d\,E\,W$ and $d\,d'\,h$ give (b) $E\,W/d\,W = d\,d'/d'\,h$; hence, dividing (a) by (b), $G\,W/E\,W = d'\,h/d'\,h''$, which is equivalent to $(E\,W - G\,W)/E\,W = (d'\,h'' - d'\,h)/d'\,h''$, *i. e.* (c) $E\,G/E\,W = h''\,h/d'\,h''$; but the similar triangles $V\,E\,W$ and $d'\,h'\,h''$ give (d) $E\,W/E\,V = d'\,h''/h'\,h''$, hence, multiplying (c) by (d), $E\,G/E\,V =$ efficiency $= h''\,h/h'\,h''$. From h'' lay off a segment $h''\,h''' = h''\,h'$; then

$$\textit{Efficiency} = \frac{h''\,h}{h''\,h'''} \tag{13}$$

i. e. if $h''\,h'''$ is divided into 100 equal parts, the per cent efficiency is $h''\,h$.

Power Factor. As in every a-c. diagram the power factor can be read directly by laying off from the origin of currents O' (Fig. 6) an arbitrary scale of 100 parts in the direction $O'\,Y$ and describing from O' as center the quadrant of a circle Q through the 100th division; the power factor is the ordinate of the point of intersection of the current vector with Q.[6]

APPENDIX

Note 1

Since the core loss current is always very small, the circuit of Fig. 3 is so near to that of Fig. 2 that the truth of this statement may be considered as self-evident, the more so because the method of representing the iron loss by a constant conductance is only a makeshift in both circuits. But even if this inherent inaccuracy of all equivalent circuits is disregarded, the absence of any appreciable difference between Figs. 2 and 3 can be proved by comparing the elements which determine the circles in both cases, *i. e.*, the radii and the coordinates of the centers. For the exact circuit these elements can be found in the "Standard Handbook for Electrical Engineers," 4th ed., p. 515, or in "Arnold, Wechselstromtechnik," vol. 5, p. 94, form. 111. The elements of the locus of Fig. 3 are obtained either by making $g = 0$ in the expressions for the exact locus and adding the current covering the core loss to the ordinate of the center, or directly from Figs. 5 and 6 of the article (the results of both methods are, naturally, identical[7]). These expressions contain elements r_1, x_1, x_2, etc., which

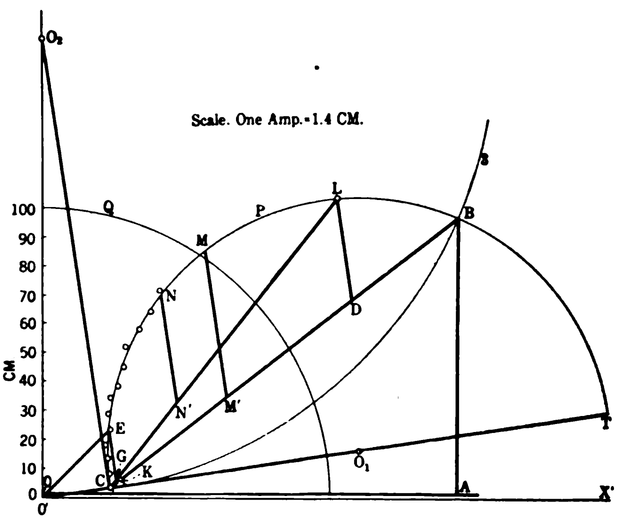

Fig. 9

vary within very wide limits; but by a suitable transformation they can be reduced to the form containing only a few elements varying within comparatively narrow limits (such as leakage coefficient, angle of tilt of the current locus, power factor at no-load, etc.), so that the entire range of combinations occurring in practise can be fairly well covered. A study of this kind made by the writer shows that the difference between the locus of the article and the exact locus is too small to be noticeable, at least in a diagram of usual dimensions (circle diameter = about 8 in.). It is, perhaps, not too much to say that this difference is of the same order of magnitude as the errors due to the inexact assumptions on which all circle diagrams are based.

These conclusions are confirmed by a comparison of the diagram with the results of brake tests made on

6. Note 2.

7. This identity, which is an additional proof of the correctness of the derivation of the locus of Fig. 3, may be of interest in view of the fact that a widely used construction of the tilted locus gives—without proof—an expression for the angle of tilt which differs from the expression (1) of the article even for the theoretical case of a motor without core loss.

a wide range of sizes extending down to the small fractional h.p. motors: In a carefully made test the brake points lie on the locus itself; in less careful commercial tests they may be scattered on both sides of it, but, *if the resistance test is made at the same temperature of the motor as the brake test,* no definite error of tilt can be observed.

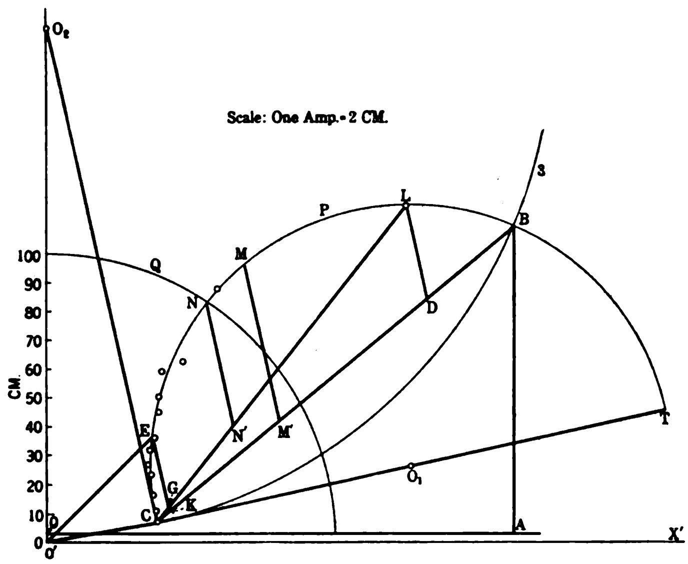

FIG. 10

NOTE 2

The application of the diagram to small motors is illustrated by the following examples (Figs. 9 and 10):

	Example (a) (Fig. 9)	Example (b) (Fig. 10)
Rating	¼ h.p. 220-volt, four-pole, two-phase, 60 ~ squirrel-cage motor	¼ .p., 220-volt, six-pole, two-phase, 60 ~ squirrel-cage motor
r_1	9.8 ohms per phase	12.53 ohms per phase
No-load test	220 = volt, 1.7 = ampere, 99 watts	220 = volt, 1.93 = ampere, 149 watts
Locked test	220 = volt, 10.4 = ampere, 3270 watts	220 = volt, 8.5 = ampere, 2565 watts
Radius of circle 3 $= \frac{V_1}{2 r_1}$	220/19.6 = 11.22 amperes	220/25.06 = 8.78 amperes
$x_s = \sim r_1 \frac{O A}{A B}$ (formula 3)	$9.8 \times \frac{10.35}{6.85} = 14.8$ ohms.	$12.53 \times \frac{8.08}{5.33} = 19$ ohms.
$x_1 = \sim .70\, x_s$	10.4 ohms	13.3 ohms
$X + x_1 = \frac{V_1}{O C}$ (formula 4)	$\frac{220}{1.69} = 130$ ohms	$\frac{220}{1.9} = 115.8$ ohms
$X =$	130 − 10.4 = 119.6 ohms	115.8 − 13.3 = 102.5 ohms
$k = \frac{X + x_1}{X}$	$\frac{130}{119.6} = 1.087$	$\frac{115.8}{102.5} = 1.13$
I_1 (full load) $= O' E$	2.34 amperes	2.62 amperes
$I_2 = C E \times k$	1.4 × 1.087 = 1.52 amperes	1.49 × 1.13 = 1.68 amperes
$r_2 = V_1 \times \frac{D L}{C L^2} \times \frac{1}{k^2}$ (formula 10)	$220 \times \frac{2.55}{9.1^2} \times \frac{1}{1.087^2} = 5.75$ ohms	$220 \times \frac{1.65}{6.98^2} \times \frac{1}{1.13^2} = 5.83$ ohms
$s = \frac{D L}{K E} \times \left(\frac{C E}{C L}\right)^2$ (formula 11)	$\frac{2.55}{1.33} \times \left(\frac{1.4}{9.1}\right)^2 = 4.53$ per cent	$\frac{1.65}{1.34} \times \left(\frac{1.49}{6.98}\right)^2 = 5.6$ per cent
Power factor at full load	71.3 per cent	70.8 per cent
Constant loss = no-load loss $- 2 I_0^2 r_1$	99 − 57 = 42 watts	149 − 93 = 56 watts
Primary copper loss	$2.34^2 \times 9.8 \times 2 = 107$ watts	$2.62^2 \times 12.53 \times 2 = 172$ watts
Secondary copper loss	$1.52^2 \times 5.75 \times 2 = 27$ watts	$1.68^2 \times 5.83 \times 2 = 33$ watts
Total loss at full load	42 + 107 + 27 = 176 watts	56 + 172 + 33 = 261 watts
Output	560 watts	560 watts
Input	560 + 176 = 736 watts	560 + 261 = 821 watts
Efficiency	76.1 per cent	68.2 per cent
$\frac{\text{Starting torque}}{\text{Full-load torque}} = \frac{D L}{K E}$	$\frac{2.55}{1.33} = 1.92$	$\frac{1.65}{1.34} = 1.23$
$\frac{\text{Maximum torque}}{\text{Full-load torque}} = \frac{M M'}{K E}$	$\frac{3.66}{1.33} = 2.76$	$\frac{2.75}{1.34} = 2.05$

The points from the commercial brake tests are also shown in the figures. The error of the method consists in neglecting the drop due to the flow of a current not exceeding $O' O$ in the primary impedance (r_1, x_1).

NOTE 3

It follows from this remark that the primary copper loss component is equal to $E W - K E$ (Fig. 11).

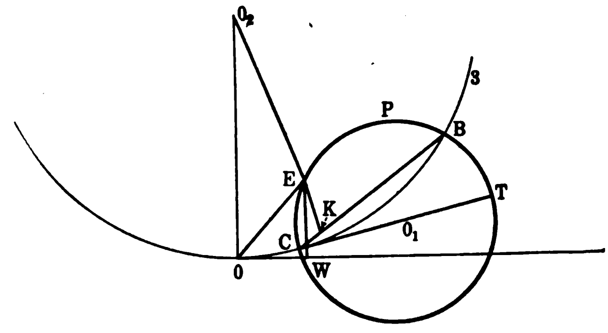

FIG. 11

That such is the case can be proved directly as follows: formula (**7a**) gives

$$O O_2^2 - O_2 E^2 = \frac{V_1}{r_1} \times K E \qquad \textbf{(a)}$$

In the triangle $O\, O_2\, E$, $O O_2^2 - O_2 E^2 + O E^2$

$$= 2 O O_2 \times E W, \text{ i. e., } O O_2^2 - O_2 E^2 + I_1^2 = \frac{V_1}{r_1} \times E W.$$

Substituting in (a)

$$\frac{V_1}{r_1} \times K E + I_1^2 = \frac{V_1}{r_1} \times E W,$$

$$\text{hence } r_1 I_1^2 = V_1 (E W - K E)$$

NOTE 4

The correction is based on the fact that the torque is measured by a segment perpendicular to the dia-

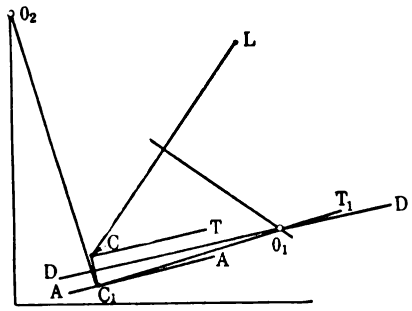

FIG. 12

meter of the locus passing through the zero-torque point (formula **7a**). With the no-load point C conidered as the zero-torque point determine the diameters $C\,T$ as shown in the article; draw $A\,A$ parallel to $C\,T$ and at a distance from it equal to the current component covering the friction, and determine by trial such a point C_1 on $A\,A$ that the perpendicular bisector $D\,D$ of $C\,C_1$, the perpendicular $C_1\,T_1$ to $C_1\,O_2$

$$\left[\text{with } C_1\,O_2 = \frac{V_1}{2\,r_1}\right]$$

and the perpendicular bisector of $C\,L$ meet at the same point O_1; this point is the center of the corrected locus because, with the relative values of $C\,C_1$ and $C_1\,O_2$ occurring in practise the segment $C\,C_1$ remains nearly perpendicular to $C_1\,O_1$, *i. e.*, the no-load point C on the corrected locus is the point corresponding to the friction torque. In practise the construction of the bisector $D\,D$ of the small segment $C\,C_1$ is not accurate, and the correction not very reliable.

Longitudinal and Transverse Heat Flow in Slot-Wound Armature Coils

BY CARL J. FECHHEIMER

Research Engineer, Westinghouse Elec. & Mfg. Co.

(*Continued from page* 248 *of JOURNAL for March* 1921.)

LIST OF SYMBOLS

$A_a = \dfrac{1}{k_c\,N\,q}\,(K_a - \epsilon_a\,I^2\,r\,\alpha)$

$A_b = \dfrac{1}{k_c\,N\,q}\,(\gamma\,K_b - \epsilon_b\,I^2\,r\,\alpha)$

$b = \dfrac{x}{1 - \dfrac{\theta_i}{\theta_m}}$ = constant used in equations for linear variation in iron temperature.

$\dfrac{B_a}{A_a} = \dfrac{K_a\,\theta_i + \epsilon_a\,I^2\,r}{K_a - \epsilon_a\,I^2\,r\,\alpha}$ = temperature of embedded copper if all heat flowed transversely.

Note: Use θ_m instead of θ_i with linear or parabolic variations of iron temperatures.

$\dfrac{B_b}{A_b} = \dfrac{\gamma\,K_b\,\theta_0 + \epsilon_b\,I^2\,r}{\gamma\,K_b - \epsilon_b\,I^2\,r\,\alpha}$ = temperature of copper in ends if all heat flowed transversely.

C_1, C_2, C_3, etc. = integration constants.

D_a = thickness of single wall of insulation in embedded portion—taken as distance from bare copper to tooth.

D_b = thickness of single wall of insulation on ends of coil.

$f = \dfrac{x^2}{1 - \dfrac{\theta_i}{\theta_m}}$ = constant when assuming iron temperature axially to be parabolic.

$G = \dfrac{\theta_m\,K_a}{b\,k_c\,N\,q}$ = constant used with linear variation in iron temperature.

$H = \dfrac{\theta_m\,K_a}{f\,k_c\,N\,q}$ = constant used with parabolic iron temperature axially.

I = current (amperes) per conductor.

$K_a = \dfrac{k_a\,Q_a}{D_a}$ = conductivity constant for particular coil (embedded portion).

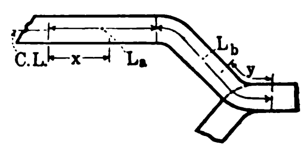
$K_b = \dfrac{k_b\,Q_b}{D_b}$ = conductivity constant for particular coil (end winding portion).

k_a = thermal conductivity of insulation (embedded portion).

k_b = thermal conductivity of insulation (end windings).

k_c = thermal conductivity of copper in watts per unit area per unit length per deg. cent.

k' = emissivity constant for heat dissipation from end windings in watts per unit surface per deg. cent.



L_a = distance from point of max. temp. to end of core; this is usually 1/2 core length.

L_b = half end winding length, at one end only.
L_t = sum of L_a and L_b.
N = number of conductors per coil.
($N\,q$ = cross-section area of copper in one coil.)
Q_a = average surface (in embedded portion) of one coil through which heat flows transversely, per unit length axially.
Q_b = average surface (in end windings) of one coil through which heat flows transversely, per unit length axially.
Q' = outside surface of one coil in end winding per unit length longitudinally.
q = area of cross-section of one conductor.
r = resistance in ohms of copper in one coil per unit length axially at zero deg. cent.
W = heat (expressed in watts) generated between zero point of reference and some other point (x or y).
W_1 = heat (expressed in watts) flowing transversely through insulation from point *0* to x (or y).
W_2 = heat (expressed in watts) flowing longitudinally along copper from point x (or $y + d\,y$) to point $x + d\,x$ (or y).
x = distance from point of max. temp. (usually center of core) to point x.
y = distance from point of min. temp. (taken as extreme end) to point y.

Greek Letters

α = temperature coefficient of copper = 0.00427 at zero deg. cent.

$$\beta = \frac{\sqrt{A_b}\tanh\sqrt{A_b}\,L_b}{\sqrt{A_a}\tanh\sqrt{A_a}\,L_a}$$

$$\gamma = \frac{1}{1 + \dfrac{K_b}{k'\,Q'}}$$

Δ = current density in copper amperes per unit area.
ϵ_a = eddy current ratio for embedded portion = ratio of actual loss to nominal $I^2 R$ (See Gilman's formulas and curves A. I. E. E., June, 1920)
ϵ_b = eddy current ratio for end winding portion.

$$\theta_{a0} = \frac{B_a}{A_a}$$

θ_a = temperature, deg. cent. of copper, at a point x in embedded portion.

$$\theta_{b0} = \frac{B_b}{A_b}$$

θ_b = temperature, deg. cent. of copper at a point y in end winding.
θ_s = temperature, deg. cent., of external surface, at a point y in end windings.
θ_i = temperature of iron adjacent to coils at a point x axially, or the average iron temperature when constant iron temperature is assumed.
θ_L = temperature of copper at end of core.
θ_m = temperature of iron, maximum, when parabolic or linear variation of iron temperature is assumed.
θ_{max} = maximum temperature of copper (embedded portion).

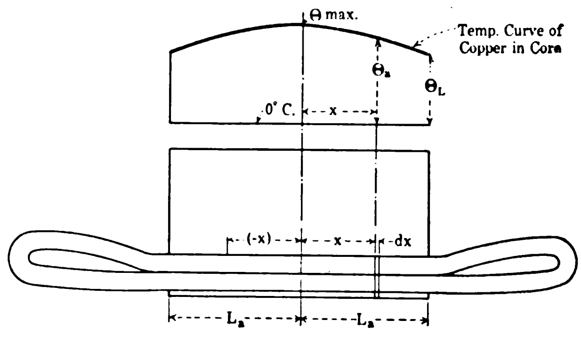


FIG. 1

θ_{min} = minimum temperature of copper (end windings)
θ_0 = temperature of air striking end windings.
θ_{av} = average temperature of winding.
ρ = resistance of unit volume of copper at zero deg. cent. (= 0.625×10^{-6} ohms per inch per sq. in.)

CASE I—CONSTANT IRON TEMPERATURE STEADY STATE

If the machine has run for a long enough period of time to secure constant temperatures (steady state), power expressed in watts may be used instead of energy, expressed in joules or calories, for the heat generated, dissipated, etc. Calling W the heat generated by $I^2 R$ and eddy currents in the copper, the total heat generated from $x = 0$ to $x = x = \int_0^x d\,W$.

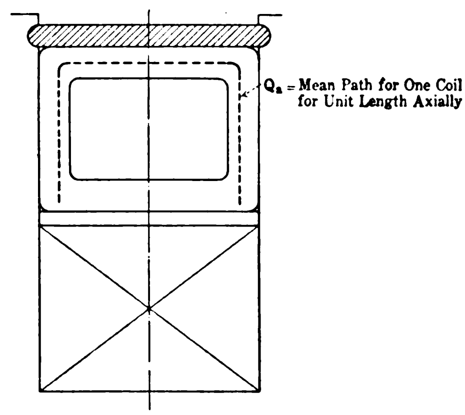

FIG. 2

(See Fig. 1.) This heat must either flow transversely through the insulation, or longitudinally along the copper toward the coil ends. If W_1 is the transverse flow, that heat flow from 0 to $x = \int_0^x d\,W_1$. After

deducting the transverse heat flow from the total generated heat, the remainder must be the longitudinal heat flow; or if W_2 is the heat which flows longitudinally beyond x,

$$W_2 = \int_0^x d\,W - \int_0^x d\,W_1 \qquad (1)$$

The loss in thin lamina $d\,x$ is:

$$d\,W = \frac{\epsilon_a\,\rho\,(1 + \alpha\,\theta_a)\,I^2\,N\,d\,x}{q} \qquad (2)$$

Considering the average heat path through the insulation to have area of Q_a for unit length axially, the area for length "dx" is $Q_a\,dx$, and the traverse heat flow is (Fig. 2):

$$d\,W_1 = \frac{k_a\,(\theta_a - \theta_i)\,Q_a\,dx}{D_a} \qquad (3)$$

If "$d\,\theta_a$" is the difference in temperature between the two sides of lamina "dx," the heat flow from one side of the lamina to the other is:

$$W_2 = -\,k_c\,(N\,q)\,\frac{d\,\theta_a}{dx} \qquad (4)$$

The negative sign is used in (4), because θ_a decreases as x increases.

Substituting the values for W, W_1, and W_2 from (2), (3), and (4) in (1), and differentiating,

$$-\,k_c\,N\,q\,\frac{d^2\,\theta_a}{d\,x^2} = \frac{\epsilon_a\,\rho\,(1 + \alpha\,\theta_a)\,I^2\,N}{q} - \frac{(\theta_a - \theta_i)\,k_a\,Q_a}{D_a} \qquad (5)$$

Or,

$$\frac{d^2\,\theta_a}{d\,x^2} - \frac{1}{k_c\,N\,q}\left(\frac{k_a\,Q_a}{D_a} - \frac{\epsilon_a\,\rho\,I^2\,N\,\alpha}{q}\right)\theta_a = -\left(\frac{\epsilon_a\,\rho\,I^2\,N}{q} + \frac{k_a\,Q_a}{D_a}\,\theta_i\right)\frac{1}{k_c\,N\,q} \qquad (6)$$

Writing

$$A_a = \frac{1}{k_c\,N\,q}\left(\frac{k_a\,Q_a}{D_a} - \frac{\epsilon_a\,\rho\,I^2\,N\,\alpha}{q}\right) = \frac{1}{k_c\,N\,q}\,(K_a - \epsilon_a\,I^2\,r\,\alpha) \qquad (7)$$

and

$$B_a = \frac{1}{k_c\,N\,q}\left(\frac{k_a\,Q_a}{D_a}\,\theta_i + \frac{\epsilon_a\,\rho\,I^2\,N}{q}\right) = \frac{1}{k_c\,N\,q}\,(K_a\,\theta_i + \epsilon_a\,I^2\,r) \qquad (8)$$

equation (6) becomes:

$$\frac{d^2\,\theta_a}{dx^2} - A_a\,\theta_a = -\,B_a \qquad (9)$$

Or,

$$\frac{d^2}{dx^2}\left(\theta_a - \frac{B_a}{A_a}\right) - A_a\left(\theta_a - \frac{B_a}{A_a}\right) = 0$$

Considering $\left(\theta_a - \frac{B_a}{A_a}\right)$ as the dependent variable a general solution will be recognized as:

$$\left(\theta_a - \frac{B_a}{A_a}\right) = C'\,e^{\sqrt{A_a}\,x} + C''\,e^{-\sqrt{A_a}\,x}$$

Since $e^u = \cosh u + \sinh u$

and $e^{-u} = \cosh u - \sinh u,$

the solution in more convenient form may be written as:

$$\theta_a = C_1 \cosh \sqrt{A_a}\,x + C_2 \sinh \sqrt{A_a}\,x + \frac{B_a}{A_a} \qquad (10)$$

In most machines, the temperature is a maximum for $x = 0$, that is at the center of the core. That is, one terminal condition is that $\frac{d\,\theta_a}{d\,x} = 0$ for $x = 0$.

$$\frac{d\,\theta_a}{d\,x} = \sqrt{A_a}\,C_1 \sinh \sqrt{A_a}\,x + \sqrt{A_a}\,C_2 \cosh \sqrt{A_a}\,x = 0$$

Thus $C_2 = 0$ for $x = 0$.

The other terminal condition is determined by making $\theta_a = \theta_L$ for $x = L_a$ (see Fig. 1). Method for evaluating θ_L is given subsequently.

$$\theta_L = C_1 \cosh \sqrt{A_a}\,L_a + \frac{B_a}{A_a}$$

Or $$C_1 = -\,\frac{\theta_{a0} - \theta_L}{\cosh \sqrt{A_a}\,L_a}$$

Where θ_{a0} has been written for $\frac{B_a}{A_a}$.

Then $$\theta_a = \theta_{a0} - \left(\frac{\theta_{a0} - \theta_L}{\cosh \sqrt{A_a}\,L_a}\right)\cosh \sqrt{A_a}\,x \qquad (11)$$

Putting $x = 0$ for maximum temperature,

$$\theta_{max} = \theta_{a0} - \frac{(\theta_{a0} - \theta_L)}{\cosh \sqrt{A_a}\,L_a} \qquad (12)$$

For very long cores, $\cosh \sqrt{A_a}\,L_a$ increases and becomes so large that the temperature at the middle of the core becomes:

$$\theta'_{max} = \theta_{a0} = \frac{B_a}{A_a} = \frac{\left(\frac{k_a\,Q_a}{D_a}\right)\theta_i + \frac{\epsilon_a\,\rho\,I^2\,N}{q}}{\frac{k_a\,Q_a}{D_a} - \frac{\epsilon_a\,\rho\,I^2\,N}{q}\,\alpha} = \frac{K_a\,\theta_i + \epsilon_a\,I^2\,r}{K_a - \epsilon_a\,I^2\,r\,\alpha} \qquad (13)$$

Equation (13) is quite important, as it is the expression for transverse heat flow without considering the longitudinal flow, and takes into account the influence of the temperature coefficient α. If α is neglected, (13) becomes:

$$\theta'_{max.} = \theta\,i + \frac{\epsilon_a\,I^2\,r}{K_a} = \theta\,i + \frac{D_a}{k_a\,Q_a}\,\epsilon_a\,I^2\,r \qquad (14)$$

This is a well-known form, being the sum of the iron temperature and the transverse thermal drop.

In order that θ_L be evaluated, it is essential to consider the heat flow from the embedded portions of the coils to the ends, and then the flow along the copper, as well as the transverse flow in the ends and the heat dissipation from the coil-end surfaces must be brought into the equations. The equations for temperatures in the end windings must be combined with those applying to the embedded portion. The assumption was made in solving the heat flow problem for the embedded portions that the temperature of the outside of the coil in contact with the iron was the same as the temperature of the iron, $\theta\, i$. The parallel assumption for the ends is scarcely admissible, inasmuch as the temperatures of the outside surfaces of the coil-ends are somewhat higher than the surrounding air.

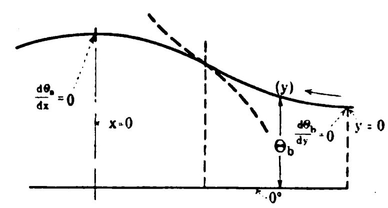

FIG. 3

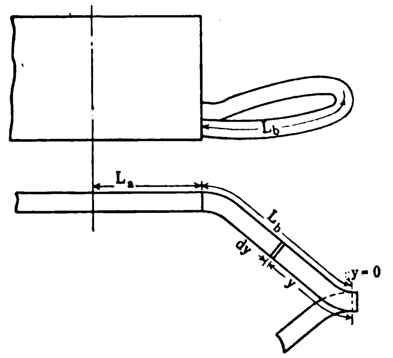

FIG. 4

Calling k' the emissivity from the coil end surfaces in watts per unit surface per degree difference in temperature between the surfaces and the surrounding air, Q' the surface per unit length of end connection, and $d\,W_1$ the watt dissipation to the air in length $d\,y$, the difference in temperature between the coil-end surface and surrounding air is:

$$(\theta_s - \theta_0) = \frac{1}{k'\,Q'}\;\frac{d\,W_1}{d\,y}$$

And as previously,

$$d\,W_1 = \frac{k_b\,(\theta_b - \theta_s)\,Q_b\,d\,y}{D_b}$$

Combining these two equations,

$$d\,W_1 = \frac{(\theta_b - \theta_0)\,k_b\,Q_b\,Q'\,k'\,d\,y}{k'\,Q'\,D_b + k_b\,Q_b}$$

$$= (\theta_b - \theta_0)\;\gamma\;\frac{k_b\,Q_b}{D_b}\;d\,y \qquad (15)$$

Where $\gamma = \dfrac{k'\,Q'\,D_b}{k'\,Q'\,D_b + k_b\,Q_b}$

$$= \frac{1}{1 + \dfrac{k_b\,Q_b}{D_b}\;\dfrac{1}{k'\,Q'}} = \frac{1}{1 + \dfrac{K_b}{k'\,Q'}} \qquad (16)$$

The heat generated in thin lamina $d\,y$, is, as before:

$$d\,W = \frac{\epsilon_b\,\rho\,(1 + \alpha\,\theta_b)\,I^2\,N}{q}\;d\,y \qquad (17)$$

Taking y to be zero at the end of coil (Fig. 4), and to be positive to the left, it is clear that the heat (expressed in watts) that flows along the copper from the point $y + d\,y$ to the point y is:

$$W_2 = +\,k_c\,N\,q\;\frac{d\,\theta_b}{d\,y} \qquad (18)$$

In this case W_2 is positive because θ_b decreases as y decreases.

Evidently, the heat that flows into the copper longitudinally at point y (from left to right), (W_2), + the heat generated in copper from o to y, $\left(\int_o^y d\,W\right)$, must flow through the insulation to the outside surface of the coil where it is dissipated (by forced air convection currents in the usual case)[8]. That is:

$$W_2 + \int_{y=o}^{y=y} d\,W = \int_{y=o}^{y=y} d\,W_1 \qquad (19)$$

Substituting in (**19**) from (**15**), (**17**) and (**18**),

$$k_c\,N\,q\;\frac{d\,\theta_b}{d\,y} + \frac{\epsilon_b\,\rho\,I^2\,N}{q}\int_o^y (1 + \alpha\,\theta)\,d\,y$$

$$= \frac{\gamma\,k_b\,Q_b}{D_b}\int_o^y (\theta_b - \theta_0)\,d\,y \qquad (20)$$

Differentiating and combining,

$$\frac{d^2\,\theta_b}{d\,y^2} - \frac{1}{k_c\,N\,q}\left(\frac{\gamma\,k_b\,Q_b}{D_b} - \frac{\epsilon_b\,\rho\,I^2\,N}{q}\,\alpha\right)\theta_b$$

$$= -\,\frac{1}{k_c\,N\,q}\left(\frac{\gamma\,k_b\,Q_b}{D_b}\;\theta_0 + \frac{\epsilon_b\,\rho\,I^2\,N}{q}\right) \qquad (20)$$

Or

$$\frac{d^2\,\theta_b}{d\,y^2} - A_b\,\theta_b = -\,B_b \qquad (21)$$

Where

$$A_b = \frac{1}{k_c\,N\,q}\left(\frac{\gamma\,k_b\,Q_b}{D_b} - \frac{\epsilon_b\,\rho\,I^2\,N}{q}\,\alpha\right)$$

8. Another way is to consider y as negative, reverse limits of integrals, and W_2 then as negative. That is, however, slightly more difficult to follow, and has, therefore, not been employed. The result is the same.

$$= \frac{1}{k_c N q} (\gamma K_b - \epsilon_b I^2 r \alpha) \quad (22)$$

and

$$B_b = \frac{1}{k_c N q} \left(\frac{\gamma k_b Q_b}{D_b} \theta_0 + \frac{\epsilon_b \rho I^2 N}{q} \right)$$

$$= \frac{1}{k_c N q} (\gamma K_b \theta_0 + \epsilon_b I^2 r) \quad (23)$$

Equation (**21**) is of same form as equation (**9**), so that a general solution is:

$$\theta_b = C_3 \cosh \sqrt{A_b}\, y + C_4 \sinh \sqrt{A_b}\, y + \frac{B_b}{A_b} \quad (24)$$

The terminal conditions for evaluating the constants of integration C_3 and C_4 are that for $y = 0, \frac{d\theta}{dy} = 0$ (that is, the temperature is at minimum value for $y = 0$); and that $\theta_b = \theta_L$ for $y = L_b$.

As for the embedded portion, the first condition gives $C_4 = 0_1$ and the second:

$$C_3 = \frac{\theta_L - \theta_{b0}}{\cosh \sqrt{A_b} L_b}$$

Therefore,

$$\theta_b = \theta_{b0} + \frac{(\theta_L - \theta_{b0})}{\cosh \sqrt{A_b} L_b} \cosh \sqrt{A_b}\, y \quad (25)$$

Where θ_{b0} has been written for $\frac{B_b}{A_b}$

The minimum temperature is for $y = 0$:

$$\theta_{min} = \theta_{b0} + \frac{(\theta_L - \theta_{b0})}{\cosh \sqrt{A_b} L_b} \quad (26)$$

With very long ends, L_b approaches infinity, so that

$$\theta'_{min} = \theta_{b0} = \frac{\gamma K_b \theta_0 + \epsilon_b I^2 r}{\gamma K_b - \epsilon_b I^2 r \alpha} \quad (27)$$

Equation (**27**) is similar to (**13**) and is the expression for temperature when the generated heat at any spot flows transversely through the insulation, uninfluenced by any longitudinal flow.

The equation for temperature in the embedded portion may now be united with the equation for temperature in the ends. The curves for temperatures for the two portions join at point $x = L_a$, or $y = L_b$. (The continuation of those curves beyond that point are shown by the dotted curves in Fig. 3). The heat flowing from the embedded portion to the ends at the point $x = L_a$ is $- k_c N q \left. \frac{d\theta_a}{dx} \right]_{x = L_a}$ (equation (**4**), and the heat received by the ends at $y = L_b$ is $+ k_c N q \left. \frac{d\theta_b}{dy} \right]_{y = L_b}$ (equation (**18**)). These two must be equal to each other. Substituting for θ_a from (**11**) and for θ_b from (**25**), performing the differentiation, equating and substituting L_a for x and L_b for y, the value of θ_L is obtained after simplifying:

$$\theta_L = \frac{\theta_{a0} + \dfrac{\sqrt{A_b} \tanh \sqrt{A_b} L_b}{\sqrt{A_a} \tanh \sqrt{A_a} L_a} \theta_{b0}}{1 + \dfrac{\sqrt{A_b} \tanh \sqrt{A_b} L_b}{\sqrt{A_a} \tanh \sqrt{A_a} L_a}} \quad (28)$$

Writing

$$\beta = \frac{\sqrt{A_b} \tanh \sqrt{A_b} L_b}{\sqrt{A_a} \tanh \sqrt{A_a} L_a} \quad (28a)$$

and

$$\theta_L = \frac{\theta_{a0} + \beta \theta_{b0}}{1 + \beta} \quad (29)$$

With the use of equation (**29**), θ_a, θ_{max}, θ_b and θ_{min} may be evaluated by substituting for θ_L in (**11**), (**12**), (**25**) and (**26**) respectively; or θ_L may be eliminated between (**29**) and the other equations, and the following obtained:

$$\theta_a = \theta_{a0} - \left(\frac{\theta_{a0} - \theta_{b0}}{\cosh \sqrt{A_a} L_a} \right) \frac{\beta}{(1 + \beta)} \cosh \sqrt{A_a}\, x \quad (30)$$

$$\theta_{max} = \theta_{a0} - \frac{(\theta_{a0} - \theta_{b0})}{\cosh \sqrt{A_a} L_a} \cdot \frac{\beta}{(1 + \beta)} \quad (31)$$

$$\theta_b = \theta_{b0} + \left(\frac{\theta_{a0} - \theta_{b0}}{1 + \rho} \right) \frac{\cosh \sqrt{A_b}\, y}{\cosh \sqrt{A_b} L_b} \quad (32)$$

In many machines, $\sqrt{A_a}$ may be taken equal to $\sqrt{A_b}$, and L_a equal to L_b; then $\beta = 1$, and the arithmetical work is simplified somewhat. Then

$$\theta_L = \frac{\theta_{a0} + \theta_{b0}}{2} \quad \text{and}$$

$$\theta_{max} = \theta_{a0} - \frac{\theta_{a0} - \theta_{b0}}{2 \cosh \sqrt{A_a} L_a}, \text{ etc.}$$

The temperature measured by resistance is the average temperature, which may be calculated as:

$$\theta_{av} = \frac{1}{L_a + L_b} \left[\int_{x=0}^{x=L_a} \theta_a\, dx + \int_{y=0}^{y=L_b} \theta_b\, dy \right]$$

Substituting for θ_a and θ_b from (**30**) and (**32**), integrating, and simplifying, calling $L_a + L_b = L_t$,

$$\theta_{av} = \frac{1}{L_t} \left[\theta_{a0} L_a + \theta_{b0} L_b + \left(\frac{\theta_{a0} - \theta_{b0}}{1 + \beta} \right) \left(\frac{\tanh \sqrt{A_b} L_b}{\sqrt{A_b}} - \frac{\beta \tanh \sqrt{A_a} L_a}{\sqrt{A_a}} \right) \right] \quad (33)$$

For the slot portion,

$$\theta_{av} = \theta_{a0} - \left[\left(\frac{\theta_{a0} - \theta_{b0}}{L_a} \right) \left(\frac{\beta}{1 + \beta} \right) \frac{\tanh \sqrt{A_a} L_a}{\sqrt{A_a}} \right] \quad (33a)$$

If A_a be taken equal to A_b, and L_a equal to L_b,

$$\theta_{av} = 1/2\,(\theta_{a0} + \theta_{b0}) \qquad \textbf{(33b)}$$

That is, under the assumptions, the average temperature is simply the arithmetical mean of the maximum and minimum copper temperatures obtainable with very long coils.

Equations Derived From the Preceding

Before leaving the equations for constant core temperature, a number of other solutions will be treated. The first will be to show how some of the equations given in the foregoing reduce to some forms previously derived. The second will be the derivation of an equation for calculating the temperature of the external surface of the coil-ends while the machine is in operation under steady conditions. The third will be the derivation of equations for calculating (a) the heat (in watts) flowing along the copper at any point; (b) the heat flowing through the insulation between the center and any points; (c) the heat generated between the center and any point.

If in equation (**6**), the temperature coefficient α be taken as zero, and assume that the wall of insulation offers so much resistance to the flow of heat that there is longitudinal flow only, that is, if Q_a be taken equal to zero, the equation reduces to:

$$\frac{d^2\,\theta}{d\,x^2} = -\frac{\epsilon_a\,\rho}{k_c}\left(\frac{I}{q}\right)^2 = -\frac{\epsilon_a\,\rho}{k_c}\,\Delta^2 \qquad \textbf{(34)}$$

For the first integral,

$$\frac{d}{d\,x}\left(\frac{d\,\theta}{d\,x}\right) = -\frac{\epsilon_a\,\rho}{k_c}\,\Delta^2, \quad \text{or}$$

$$\frac{d\,\theta}{d\,x} = -\frac{\epsilon_a\,\rho}{k_c}\,\Delta^2\,x + C_5$$

Integrating again,

$$\theta = -\frac{\epsilon_a\,\rho}{2\,k_c}\,\Delta^2\,x^2 + C_5\,x + C_6$$

When $x = 0$, $\theta = \theta_{max}$. Therefore $C_6 = \theta_{max}$.

When $x = 0$, $\frac{d\,\theta}{d\,x} = 0$. Therefore $C_5 = 0$.

Hence the equation becomes:

$$\theta = \theta_{max} - \frac{\epsilon_a\,\rho}{2\,k_c}\,\Delta^2\,x^2 \qquad \textbf{(35)}$$

If $x = L_a$, and $\theta = \theta_L$

$$\theta_{max} = \theta_L + \frac{\epsilon\,\rho\,\Delta^2}{k_c}\;\frac{L^2}{2} \qquad \textbf{(36)}$$

This is a well-known equation.

If similar assumptions are made, except that α be not taken as zero,

$$\theta_{a0} = \frac{B_a}{A_a} = -\frac{1}{\alpha}\ (\text{for } Q_a = 0), \qquad \text{and}$$

$$\sqrt{A_a} = \sqrt{-\frac{\epsilon_a\,\rho\,I^2\,\alpha}{k_c\,q^2}} = j\,\Delta\sqrt{\frac{\epsilon_a\,\rho\,\alpha}{k_c}}$$

where $j = \sqrt{-1}$ and $\Delta = \frac{I}{q}$

Substituting in equation (**12**), and remembering that $\cosh j\,u = \cos u$, the expression for this special case becomes:

$$\theta_{max} = \frac{1/\alpha + \theta_L}{\cos\left(\Delta\,L_a\sqrt{\frac{\epsilon_a\,\rho\,\alpha}{k_c}}\right)} - \frac{1}{\alpha} \qquad \textbf{(37)}$$

It is interesting to compare equation (**37**) with an equation in the paper by H. D. Symonds and Miles Walker: "The Heat Paths in Electrical Machinery" Institution of Elec. Eng. 1912. Using same values for constants as they used, $1/\alpha = 273$, $\epsilon_a = 1$, $\Delta =$ amp. per sq. cm., $\rho = 1.6 \times 10^{-6}$, $k_c = 3$, and taking θ in absolute deg. cent. (**37**) becomes:

$$\theta_{max} = \frac{\theta_L}{\cos\left(\frac{4.43}{10^5}\,\Delta\,L_a\right)}, \qquad \textbf{(37a)}$$

the same as in their paper.

The temperature of the coil end surface may be calculated while the machine is in operation—to check the ordinary thermometer measurements, the location of the thermometer bulb (y) being known, by solving the equations preceding equation (**15**) for $\theta_e\left(\text{thus eliminating } \frac{d\,W_1}{d\,y}\right)$

$$\theta_e = \frac{K_b\,\theta_b + k'\,Q'\,\theta_0}{K_b + k'\,Q'} \qquad \textbf{(38)}$$

In using this equation it is necessary to first determine the internal temperature θ_b at the particular point on the end windings by means of equation (**25**) or (32). The formula is not applicable after shut-down, because then the internal temperatures no longer show the temperature gradients as given by the equations derived, but heat flows from high to low temperatures, thus equalizing, to some extent, the copper temperatures. The external surface temperatures are influenced somewhat by this equalization, and that is one reason why the thermometers on the coil ends frequently show an increase in temperature after shut-down.

The heat flow along the copper is [equation (**4**)] from $x = 0$ to $x = x$ given by $W_2 = -\,k_c\,N\,q\,\frac{d\,\theta_a}{d\,x}$.

Substituting for θ_a from (**30**), and differentiating,

$$(W_2)_a = k_c\,N\,q\,\sqrt{A_a}\,\beta\,\frac{(\theta_{a0} - \theta_{b0})}{(1+\beta)}\;\frac{\sinh\sqrt{A_a}\,x}{\cosh\sqrt{A_a}\,L_a} \qquad \textbf{(39a)}$$

The transverse heat flow is [equation (3)]:

$$(W_1)_a = \int_0^x K_a (\theta_a - \theta_i)\, d x = K_a \Big[(\theta_{a0} - \theta_i)\, x$$

$$- \frac{(\theta_{a0} - \theta_{b0})}{\sqrt{A_a}} \; \frac{\beta}{(1 + \beta)} \cdot \frac{\sinh \sqrt{A_a}\, x}{\cosh \sqrt{A_a}\, L_a} \Big] \quad \textbf{(40a)}$$

The heat generated between $x = 0$ and $x = x$ is

$$(W)_a = \int_0^x \frac{\epsilon_a \rho I^2 N}{q} (1 + \alpha\, \theta_a)\, d x$$

$$= \epsilon_a I^2 r \Big[(1 + \alpha\, \theta_{a0})\, x$$

$$- \frac{\alpha\, (\theta_{a0} - \theta_{b0})}{\sqrt{A_a}} \left(\frac{\beta}{1 + \beta} \right) \left(\frac{\sinh \sqrt{A_a}\, x}{\cosh \sqrt{A_a}\, L_a} \right) \Big] \quad \textbf{(41a)}$$

$\left(\text{For } x = L_a, \; \frac{\sinh \sqrt{A_a}\, x}{\cosh \sqrt{A_a}\, L_a} \text{ becomes } \tanh \sqrt{A_a}\, L_a \right)$

Similar equations may be derived for the ends as follows:

$$(W_2)_b = k_c N q \sqrt{A_b}\, \frac{(\theta_{a0} - \theta_{b0})}{(1 + \beta)} \; \frac{\sinh \sqrt{A_b}\, y}{\cosh \sqrt{A_b}\, L_b} \quad \textbf{(39b)}$$

$$(W_1)_b = \gamma K_b \Big[(\theta_{b0} - \theta_0)\, y + \frac{(\theta_{a0} - \theta_{b0})}{\sqrt{A_b}\, (1 + \beta)} \; \frac{\sinh \sqrt{A_b}\, y}{\cosh \sqrt{A_b}\, L_b} \Big] \quad \textbf{(40b)}$$

$$(W)_b = \epsilon_b I^2 r \Big[(1 + \alpha\, \theta_{b0})\, y + \frac{\alpha\, (\theta_{a0} - \theta_{b0})}{\sqrt{A_b}\, (1 + \beta)} \; \frac{\sinh \sqrt{A_b}\, y}{\cosh \sqrt{A_b}\, L_b} \Big] \quad \textbf{(41b)}$$

It may also be of interest to determine the rate of generation at any point; this is given from equations (**2**) or (**17**), thus:

$$\frac{d W}{d x} = \epsilon_a I^2 r\, (1 + \alpha\, \theta_a) \text{ watts per unit length.}$$

$$\frac{d W}{d y} = \epsilon_b I^2 r\, (1 + \alpha\, \theta_b) \quad \text{" \quad " \quad " \quad "}$$

Similarly the rate of flow of heat transversely through the insulation is from (**3**) and (**15**):

$$\frac{d W_1}{d x} = K_a\, (\theta_a - \theta_i) \text{ watts per unit length.}$$

$$\frac{d W_1}{d y} = \gamma K_b\, (\theta_b - \theta_0) \quad \text{" \quad " \quad " \quad "}$$

Case II. Linear Variation of Iron Temperature Steady State

In some machines, as for example in certain axially ventilated armatures, the core and tooth temperatures are at maximum value at the center, and decrease in linear relation from the center to the end of the core, as indicated in the upper part of Fig. 5. The equation of the straight line may readily be written, if the values of the temperature are known at two points, say for $x = 0$, and for $x = L_a$, thus:

$$\theta_i = \theta_m \left(1 - \frac{x}{b} \right) \quad \textbf{(42)}$$

θ_m is the maximum tooth temperature, and b is a constant.[9] The transverse heat flow is (see equation (**3**)):

$$d W_1 = (\theta_a - \theta_i)\, \frac{k_a Q_a}{D_a}\, d x$$

$$= \left(\theta_a - \theta_m + \theta_m \frac{x}{b} \right) \frac{k_a Q_a}{D_a}\, d x \quad \textbf{(43)}$$

The loss in thin lamina $d x$ and the longitudinal flow are the same as before (see equations (**2**) and (**4**)). Also the fundamental equation co-ordinating $d W$, $d W_1$ and W_2 is the same as previously (equation (**1**)). Substituting for $d W$, $d W_1$, and W_2 in equation (**1**):

$$- k_c N q\, \frac{d\, \theta_a}{d x} + \int_0^x \left(\theta_a - \theta_m + \frac{\theta_m}{b} x \right) \frac{k_a Q_a}{D_a}\, d x = \int_0^x \frac{\epsilon_a \rho I^2 N (1 + \alpha\, \theta_a)}{q}\, d x$$

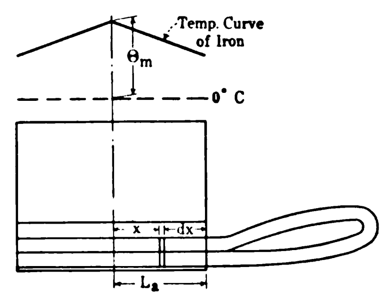

Fig. 5

Differentiating and combining,

$$\frac{d^2\, \theta_a}{d x^2} - \left(\frac{k_a Q_a}{D_a} - \frac{\epsilon_a \rho I^2 N \alpha}{q} \right) \frac{1}{k_c N q}\, \theta_a = \frac{\theta_m}{b}\, \frac{k_a Q_a}{D_a}\, \frac{1}{k_c N q}\, x$$

$$- \left(\frac{\epsilon_a \rho I^2 N}{q} + \frac{k_a Q_a}{D_a}\, \theta_m \right) \frac{1}{k_c N q} \quad \textbf{(44)}$$

$$\text{Or} \quad \frac{d^2\, \theta_a}{d x^2} - A_a\, \theta_a = G\, x - B_a \quad \textbf{(45)}$$

Where A_a and B_a have the same values as previously, (equations (**7**) and (**8**)), except that θ_m appears instead of θ_i, and

$$G = \frac{\theta_m}{b}\, \frac{k_a Q_a}{D_a}\, \frac{1}{k_c N q} \quad \textbf{(46)}$$

Equation (**45**) may be written:

---

9. "b" has been placed in the denominator to simplify numerical calculations.

$$\frac{d^2}{dx^2}\left(\theta_a - \frac{B_a}{A_a}\right) - A_a\left(\theta_a - \frac{B_a}{A_a}\right) = G\,x$$

This linear differential equation may be solved by the well-known method of undetermined coefficients, and a general solution is:

$$\theta_a = C_7 \cosh\sqrt{A_a}\,x + C_8 \sinh\sqrt{A_a}\,x - \frac{G}{A_a}\,x + \frac{B_a}{A_a} \qquad (47)$$

As in the case for constant core temperature, one terminal condition may be taken as $\frac{d\,\theta}{d\,x} = 0$ for $x = 0$. Then:

$$C_8 = \frac{G}{A_a\sqrt{A_a}} \qquad (48)$$

And the other terminal condition is $\theta_a = \theta_L$ for $x = L_a$:

$$C_7 = \frac{-\,\theta_{a0} + \theta_L + \frac{G}{A_a}\,L_a - \frac{G}{A_a\sqrt{A_a}}\sinh\sqrt{A_a}\,L_a}{\cosh\sqrt{A_a}\,L_a} \qquad (49)$$

Where θ_{a0} has been written for $\frac{B_a}{A_a}$. The solution may now be written as:

$$\theta_a = \theta_{a0} + \frac{G}{A_a\sqrt{A_a}}\sinh\sqrt{A_a}\,x - \frac{G}{A_a}\,x - \left[\theta_{a0} - \theta_L + \frac{G}{A_a}\left(\frac{\sinh\sqrt{A_a}\,L_a}{\sqrt{A_a}} - L_a\right)\right]\frac{\cosh\sqrt{A_a}\,x}{\cosh\sqrt{A_a}\,L_a} \qquad (50)$$

As in deriving equation (**28**), the slope of the curve for the embedded portion $\left(-\frac{d\,\theta_a}{d\,x}\right)$ for $x = L_a$, is equal to the slope for the ends $\left(+\frac{d\,\theta_b}{d\,y}\right)$ for $y = L_b$, obtained by differentiating equation (**25**), (the condition for longitudinal flow from the embedded portion at the end of the core being equal to the heat received by the ends at the same point). Thus:

$$-\frac{G}{A_a}\cosh\sqrt{A_a}\,L_a + \frac{G}{A_a} + \left[\theta_{a0} - \theta_L + \frac{G}{A_a}\left(\frac{\sinh\sqrt{A_a}\,L_a}{\sqrt{A_a}} - L_a\right)\right]\sqrt{A_a}\tanh\sqrt{A_a}\,L_a = (\theta_L - \theta_{b0})\sqrt{A_b}\tanh\sqrt{A_b}\,L_b$$

Bringing in β as given by equation (**28a**), the above equation may be written as:

$$\theta_L = \frac{1}{1+\beta}\left(\theta_{a0} + \beta\,\theta_{b0} - \frac{G}{A_a}\left[L_a - \frac{\sinh\sqrt{A_a}\,L_a}{\sqrt{A_a}} + \frac{\cosh\sqrt{A_a}\,L_a - 1}{\sqrt{A_a}\tanh\sqrt{A_a}\,L_a}\right]\right)$$

The expression in brackets may be reduced to:

$$L_a + \frac{-\sinh^2\sqrt{A_a}\,L_a + \cosh^2\sqrt{A_a}\,L_a - \cosh\sqrt{A_a}\,L_a}{\sqrt{A_a}\sinh\sqrt{A_a}\,L_a} = L_a - \frac{\cosh\sqrt{A_a}\,L_a - 1}{\sqrt{A_a}\sinh\sqrt{A_a}\,L_a}$$

Then:

$$\theta_L = \frac{1}{1+\beta}\left[\theta_{a0} + \beta\,\theta_{b0} - \frac{G}{A_a}\left(L_a - \frac{\cosh\sqrt{A_a}\,L_a - 1}{\sqrt{A_a}\sinh\sqrt{A_a}\,L_a}\right)\right] \qquad (51)$$

This value of θ_L could be substituted in equation (**50**), and θ_a and θ_{max} found; or if substituted in equations (**25**) or (**26**), the temperatures of the ends may be found. The resulting expressions are quite complicated, and they are consequently not given here. It is believed best, to solve (**51**) and then substitute the numerical value found in the other equations.

If in equation (**50**), $x = 0$, $\theta_a = \theta_{max}$.

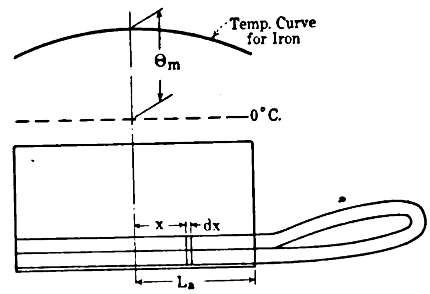

FIG. 6

$$\theta_{max} = \theta_{a0} - \left[\theta_{a0} - \theta_L + \frac{G}{A_a}\left(\frac{\sinh\sqrt{A_a}\,L_a}{\sqrt{A_a}} - L_a\right)\right]\frac{1}{\cosh\sqrt{A_a}\,L_a} \qquad (52)$$

It will be noted that these equations reduce to those for constant core temperature if $G = 0$.

CASE III. PARABOLIC VARIATION OF IRON TEMPERATURE. STEADY STATE

In most machines, especially those with radial ventilation, the core and tooth temperatures may be approximately represented by a parabola, with its maximum value at the center of the core, as indicated in Fig. 6. The equation of this curve for temperature may be written, if the values of θ_i are known at two points, say for $x = 0$, and for $x = L_a$; thus, if "f" is a constant,

$$\theta_i = \theta_m\left(1 - \frac{x^2}{f}\right) \qquad (53)$$

The transverse heat flow is:

$$d W_1 = (\theta_a - \theta_i) \frac{k_a Q_a}{D_a} d x$$

$$= \left(\theta_a - \theta_m + \theta_m \frac{x^2}{f} \right) \frac{k_a Q_a}{D_a} d x \qquad (54)$$

Substituting this value of $d W_1$ and those for $d W$ and W_2 (as found in equations (2) and (4) in equation (1),

$$- k_c N q \frac{d \theta_a}{d x} + \int_0^x \left(\theta_a - \theta_m + \frac{\theta_m x^2}{f} \right) \frac{k_a Q_a}{D_a} dx$$

$$= \int_0^x \frac{\epsilon_a \rho I^2 N (1 + \alpha \theta_a)}{q} d x$$

Differentiating and combining,

$$\frac{d^2 \theta_a}{d x^2} - (K_a - \epsilon_a I^2 r \alpha) \frac{1}{k_c N q} \theta_a =$$

$$\frac{\theta_m K_a}{f k_c N q} x^2 - (K_a \theta_m + \epsilon_a I^2 r) \frac{1}{k_c N q} \qquad (55)$$

Or

$$\frac{d^2 \theta_a}{d x^2} - A_a \theta_a = H x^2 - B_a \qquad (56)$$

Where A_a and B_a are the same as previously (equations (7) and (8)), except that θ_m appears instead of θ_i, and

$$H = \frac{\theta_m K_a}{f k_c N q} \qquad (57)$$

A general solution of this linear differential equation is:

$$\theta_a = C_9 \cosh \sqrt{A_a}\, x + C_{10} \sinh \sqrt{A_a}\, x$$

$$+ \frac{B_a}{A_a} - \frac{H}{A_a} x^2 - \frac{2 H}{A_a^2} \qquad (58)$$

When $x = 0$, $\frac{d \theta}{d x} = 0$, whence $C_{10} = 0$.

For $x = L_a$, $\theta_a = \theta_L$, whence

$$C_9 = \frac{\theta_L - \theta_{a0} + \frac{H}{A_a} L_a^2 + \frac{2 H}{A_a^2}}{\cosh \sqrt{A_a}\, L_a} \qquad (59)$$

And,

$$\theta_a = \theta_{a0} - \frac{H}{A_a} x^2 - \frac{2 H}{A_a^2} -$$

$$\frac{\theta_{a0} - \left(\theta_L + \frac{H}{A_a} L_a^2 + \frac{2 H}{A_a^2}\right)}{\cosh \sqrt{A_a}\, L_a} . \cosh \sqrt{A_a}\, x \qquad (60)$$

For $x = 0$,

$$\theta_{max} = \theta_{a0} - \frac{2 H}{A_a^2} - \frac{\theta_{a0} - \left(\theta_L + \frac{H}{A_a} L_a^2 + \frac{2 H}{A_a^2}\right)}{\cosh \sqrt{A_a}\, L_a} \qquad (61)$$

Equating the heat flow in the embedded part to that received by the ends at $x = L_a$, and $y = L_b$, after simplifying,

$$\theta_L = \frac{1}{1 + \beta} \left[\theta_{a0} + \beta \theta_{b0} - \frac{H}{A_a} \left(L_a^2 + \frac{2}{A_a} - \frac{2 L_a}{\sqrt{A_a} \tanh \sqrt{A_a}\, L_a}\right)\right] \qquad (62)$$

Having found the numerical value of θ_L, the other quantities, θ_a, θ_{max}, θ_b and θ_{min} may be found by substituting in equations (60) (61), (25) and (26) respectively.

(To be continued)

HIGH-TENSION INSULATOR PORCELAIN

ERRATUM

In the paper on the above subject, by W. D. A. Peaslee, published in the JOURNAL for May, 1920, the statements concerning the "piezo-electric effect of porcelain" should have been credited to Mr. C. C. Trieschel by whom they had been previously published in the *Journal of the American Ceramic Society* February 1919.

HYDROELECTRIC DEVELOPMENT IN CEYLON

Plans for the proposed electrification of the industries of the island of Ceylon, with an outline of the Laxapana-Aberdeen project as given in the report of Mr. J. W. Meares, electrical adviser to the Government of India, were published in the JOURNAL for September, 1920, page 843. Information has since been received that the Government of Ceylon has approved Mr. Meares' recommendations relative to the development of the Laxapana-Aberdeen hydroelectric scheme, and has ordered detailed surveys to be made.

The *Journal of The Franklin Institute*, for January, 1921, contains a long illustrated paper by R. D. Duncan, entitled "Recent Attainments in Wired Radio." Wired Radio refers to the use for communication purposes of high-frequency currents guided by wires. Mr. Duncan is a radio engineer in the Signal Corps, U. S. Army.

E. R. SHUTE, traffic engineer, Western Union Telegraph Co., New York, has returned from a trip to various technical colleges throughout the country, which he took for the purpose of scheduling the possible supply of engineering graduates for communication work.

A. I. E. E. PITTSBURGH MEETING
April 16, 1921

The 369th Institute meeting will be held in Pittsburgh, Pa., on Saturday, April 16, 1921. This meeting, under the auspices of the Pittsburgh Section of the A. I. E. E., will be a joint session with the Association of Iron and Steel Electrical Engineers.

The morning will be given over to an inspection of the Colfax station of the Duquesne Light Company and will be followed by a luncheon at the plant. The Board of Directors will also hold its meeting at the plant during the morning. A special train will leave Pittsburgh for the Colfax Station at 10:00 a. m.

The afternoon session will be held in the Auditorium of the Chamber of Commerce at Pittsburgh and will be devoted to the presentation of a paper descriptive of the Duquesne Light plant at Colfax by D. L. Galusha and C. W. E. Clarke, both of Dwight P. Robinson & Co.

An informal dinner will be served at the William Penn Hotel at 6:00 p. m. followed by the second technical session at the hotel, with two papers descriptive of the problems of 25-60 cycle conversion, by B. G. Lamme of the Westinghouse Co. and D. M. Petty of the Bethlehem Steel Co.

A complete program with titles of papers, etc. follows. The Institute paper by Messrs. Galusha and Clarke and that by Mr. Lamme are printed elsewhere in this issue of the JOURNAL.

PROGRAM

10:00 a. m. Inspection Colfax Station, Duquesne Light Co.
Special train leaves Pittsburgh, Penn. R. R. depot at 10:00 a. m.

11:00 a. m. Board of Directors Meeting, at Colfax

12:30 p. m. Luncheon at Colfax Station

3:00 p. m. Technical Session, Auditorium, Chamber of Commerce, Pittsburgh
Colfax Power Station of the Duquesne Light Company by D. L. Galusha and C. W. E. Clarke, of Dwight P. Robinson & Co.

6:00 p. m. Informal Dinner, William Penn Hotel

8:00 p. m. Technical Session, William Penn Hotel
The Frequency Problem in the Steel Industry by B. G. Lamme of the Westinghouse Elec. and Mfg. Co.
Some Results in the Change of 60-Cycle to 25-Cycle Energy by D. M. Petty of the Bethlehem Steel Company.

A. I. E. E. ANNUAL MEETING

The 307th meeting of the A. I. E. E. will be held in the Engineering Societies Building, New York, May 20, 1921. This is the Annual Meeting of the Institute, at which the result of the annual elections is announced and the report of the Board of Directors is presented. A technical program to be announced later will follow the business session.

FUTURE SECTION MEETINGS

Baltimore.—April 15, 1921. Subject: "The Problem of the Electric Motor Car and Its Relation to the Electrical Industry." Speaker: Dr. Charles P. Steinmetz, General Electric Company.

Chicago.—April 25, 1921. Joint meeting with the Electrical and Mining Sections of the Western Society of Engineers, and Association of Iron and Steel Electrical Engineers. Subjects: "Diversity Factor of Coal Mining Loads" by Mr. Carl Lee, E. E., Peabody Coal Company; "Power Distribution Systems for Coal Mines" by Mr. W. C. Adams of Allen & Garcia Company. Both papers will be illustrated with Lantern Slides.

Cleveland.—April 19, 1921. Subject: "The Automatic Railway Substation." Speaker: Mr. L. D. Bale, Cleveland Railway Company.

May 17, 1921. Annual Dinner. Subject: "Some Recent Developments in Scientific Research." Speaker: Mr. C. F. Kettering, The Dayton Engineering Laboratories.

New York.—April 22, 1921. Subject: "Engineering Education" Professor Comfort A. Adams in charge. In addition to the fact that this will be a joint meeting of the N. Y. Section A. I. E. E. and Metropolitan Section A. S. M. E., it will also be the Annual Business Meeting of the N. Y. Section of the Institute at which the results of the election of officers for the year 1921-22 will be announced. Such other business as required by the By-Laws will be transacted. Meeting will be held at 8 p. m. sharp in Auditorium, Engineering Socieites Building, 33 West 39th Street, New York.

San Francisco.—April 29, 1921. Subject: "Toll Line Practise." Speaker: Mr. J. E. Heller, Pacific Telephone & Telegraph Company.

Schenectady.—April 15, 1921. Subject: "Illumination." Speaker: Mr. W. D'A. Ryan.

Vancouver.—May 6, 1921. Subject: "Electric Power in Pulp and Paper Mills." Speaker: Mr. T. H. Crosby.

WASATCH MOUNTAINS FROM LIBERTY PARK SALT LAKE CITY

THE A. I. E. E. ANNUAL AND PACIFIC COAST CONVENTION MEETS IN SALT LAKE CITY, JUNE 21-24, 1921

Annual and Pacific Coast Convention

Salt Lake City, Utah, June 21-24, 1921

The Thirty-Seventh Annual Convention of the Institute will be held at Salt Lake City, Utah, June 21-24, 1921. For a number of years there has been a constantly increasing demand from the active Institute membership residing in the West that it be given the opportunity to act as host at an Annual Convention. The Board of Directors therefore, gladly acceded to the request adopted at the 1920 Pacific Coast Convention to combine the Annual and Pacific Coast Conventions at Salt Lake City in June, 1921. From the preliminary arrangements outlined by the Utah Section the convention this year should prove particularly interesting and profitable from many view-points. Mr. H. T. Plumb has been appointed Chairman of the Convention Committee and announces the appointment of 24 subcommittees to handle the various details.

Institute headquarters will be located at the Hotel Utah and all technical sessions will be held there.

An outline of the tentative program follows:

Tuesday, June 21

The convention will open on Tuesday morning, June 21, with the Annual Presidential Address by Arthur W. Berresford. A technical session, with the presentation of several papers, under the auspices of the Electrical Machinery Committee will follow. Directly succeeding the technical session a luncheon for the Section Delegates is scheduled. This will serve as an opportunity for the delegates to become acquainted and to discuss points of general interest. Tuesday afternoon there will be a trip on foot past the most interesting historical Latter Day Saints buildings, followed by a short lecture and organ recital in the Tabernacle. At 7:00 p. m. an auto trip has been arranged to reach the famous Wasatch Boulevard at sunset and later to Capitol Hill. A return will be made to the Hotel Utah in time for an informal reception at 9:30 p. m.

Wednesday, June 22

Wednesday morning the second technical session will be held under the auspices of the Industrial and Domestic Power Committee. For the forenoon a special Ladies Entertainment has also been scheduled with perhaps a luncheon at the Literary Club. On Wednesday afternoon a special train will leave from the Oregon Short Line depot at 1:30 p. m. over the Bingham and Garfield Railroad. This trip in addition to magnificent views of Great Salt Lake and Salt Lake Valley will provide an opportunity for Institute members to inspect a typical mining canyon, surface workings of a big mine with mills and smelters. On Wednesday evening it is hoped Prof. Karapetoff will render a piano recital, a feature which will particularly appeal to those members who have heard his recitals at previous conventions.

Thursday, June 23

Thursday morning, the technical session will be under the auspices of the Transmission and Distribution Committee. The Board of Directors will meet at luncheon, Thursday noon, and follow the luncheon with a short business meeting. Thursday afternoon is assigned to "A Look at Salt Lake City" from the sight-seeing autos or on foot with local members as guides. Arrangements will also be made for those who wish to devote the time to golf or tennis. For the after-dinner entertainment Dr. Broaddus will deliver an illustrated lecture on the wonderful can yonsof Utah.

Friday, June 24

Friday morning, June 24, is assigned for the presentation of various miscellaneous technical papers. On Friday afternoon in addition to the finals of the Golf and Tennis Tournaments a trip is planned to the Utah Power and Light Company's Terminal Station, the terminus of three 130,000-volt transmission lines, and said to be the largest outdoor substation in the world. Bathing at Saltair Beach is scheduled from 5:00 p. m. to 7:00 p. m., followed either by a dinner in the Ship Café or an old fashioned basket picnic with dancing for those who wish it.

Trips to Points of Interest

Friday evening will conclude the convention proper but for those who can arrange to stay over there are innumerable trips to be taken to points of great interest and scenic beauty, among which might be mentioned Mt. Timpanogos, Beck Hot Springs, Ogden Canyon, Zion National Park, Grand Canyon of the Colorado and the Natural Bridges and Cliff Dwellings of southeast Utah.

Sports

In addition to the regular time allotted to sports during the convention, it will be possible for members desiring to devote more attention to this feature to arrange for additional tennis or golf. The gymnasium of the Latter Day Saints immediately adjacent to the hotel will probably be available for the free use of members and will afford special bathing and exercise at any time of day.

THE A. I. E. E. MARCH MEETING

The 368th meeting of the A. I. E. E. was held in the Engineering Societies Building, New York, March 11, 1921. The meeting was called to order by Manager Charles S. Ruffner who introduced Mr. H. P. Liversidge, Chairman of the Power Stations Committee, under whose auspices the program was given.

The paper of the evening was entitled "Developments in Conversion Apparatus for Edison Systems," by T. F. Barton and T. T. Hambleton, and was presented by Mr. Barton.

A very complete discussion followed which was opened by a written communication from Mr. B. G. Lamme, read by Mr. Albrecht, and oral discussions by Messrs. A. A. Nimis, F. D. Newbury, A. M. Garrett, Raymond Bailey, Philip Torchio, Selby Haar, H. C. Albrecht and D. W. Roper with closure by Mr. Barton.

A. I. E. E. DIRECTORS MEETING

MARCH 11, 1921

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Friday, March 11, 1921, at 3:00 p. m.

There were present: Past-Presidents C. A. Adams and Calvert Townley, New York; Vice-Presidents Charles S. Ruffner, New York, Charles Robbins, Pittsburgh, L. T. Robinson and C. S. McDowell, Schenectady; Managers Walter A. Hall, Boston, Wm. A. Del Mar, W. I. Slichter, L. E. Imlay, L. F. Morehouse, and E. B. Craft, New York, F. D. Newbury, Pittsburgh; Treasurer George A. Hamilton, Elizabeth, N. J.; Secretary F. L. Hutchinson, New York.

The Board ratified the approval by the Finance Committee of monthly bills amounting to $17,997.53.

A report was presented of a meeting of the Board of Examiners held March 4, 1921; and the actions taken on applications at those meetings were approved. Upon the recommendation of the Board of Examiners the following action was taken upon pending applications: 161 Students were ordered enrolled; 334 applicants were elected to the grade of Associate; 21 applicants were elected to the grade of Member; 1 applicant was transferred to the grade of Fellow; 12 applicants were transferred to the grade of Member.

The Meetings and Papers Committee reported that a request had been received from the Marine Committee for a meeting in Conjunction with the Society of Naval Architects and Marine Engineers, to be held in New York in November, which request had not yet been acted upon by the Committee.

Attention was called to the policy adopted by the Board of Directors a few years ago of requiring the technical committees to include in their annual reports, in addition to a report of the committee's activities during the year, a brief resume of the progress of the art in the respective field of each committee; and upon the recommendation of the Committee on Coordination of Institute Activities the following resolution was adopted:

RESOLVED: That the policy of including in the annual reports of technical committees a brief resume of the progress of the art in the particular field within the scope of each committee, which was carried out last year in a very commendable manner by several of the technical committees, be reaffirmed as the policy of the Institute—in the hope that gradually these annual technical committee reports may become recognized as authoritative sources of information on the history of electrical engineering development.

Professor C. A. Adams was reappointed a representative of the Institute on the Division of Engineering of the National Research Council, for a term of three years commencing July 1, 1921.

A communication from Mr. Charles S. Ruffner was read, requesting that his name be withdrawn from nomination for the office of President.

The report of the Tellers Committee of its canvass of the nomination ballots received for the offices to be filled at the 1921 annual election, was presented; and the action taken is reported elsewhere in this issue.

A communication from the Secretary of Engineering Foundation, requesting the appointment of a committee to cooperate with the Foundation in its study of industrial education and training, was presented and referred to the Educational Committee.

A communication from the Kelvin Memorial Committee was presented, announcing the award of the first Kelvin Medal to Dr. W. C. Unwin.

In addition to these actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

A. I. E. E. ANNUAL ELECTION

At the meeting of the Board of Directors of the Institute, held in New York, March 11th, the report of the Committee of Tellers, giving the result of its canvass of the nomination ballots received for the offices to be filled at the coming annual election, was presented.

This report included the names of all candidates eligible for election, the names of those who received less than 3 per cent of the total nomination vote having been eliminated, in accordance with the requirements of the Constitution.

The Board resolved itself into a Committee of the whole, and an informal discussion followed, at the close of which the Committee arose and reported its recommendations to the Board. The Board then selected a complete ticket of "Directors' Nominees" for the respective offices, in accordance with the provisions of the Constitution. This ticket is as follows:

For President:	William McClellan, Philadelphia, Pa.	
For Vice-Presidents:	District No. 1	W. A. Hall, Boston, Mass.
	District No. 2	N. W. Storer, Pittsburgh, Pa.
	District No. 3	W. A. Del Mar, Yonkers, N. Y.
	District No. 4	C. G. Adsit, Atlanta, Ga.
	District No. 5	J. C. Parker, Ann Arbor, Mich.
	District No. 6	F. W. Springer, Minneapolis, Minn.
	District No. 7	H. W. Eales, St. Louis, Mo
	District No. 8	Robert Sibley, San Francisco, Cal.
	District No. 9	O. B. Coldwell, Portland, Ore.
	District No. 10	F. R. Ewart, Toronto, Ont.
For Managers:		A. G. Pierce, Pittsburgh, Pa.
		R. B. Williamson, Milwaukee, Wis.
		Harlan A. Pratt, New York, N. Y.
For Treasurer:		George A. Hamilton, Elizabeth, N. J.

The election ballots were mailed to the entire membership prior to April 1st, in accordance with the Constitution.

The report of the Committee of Tellers follows:

March 9, 1921

REPORT OF COMMITTEE OF TELLERS ON NOMINATION BALLOTS

To the Board of Directors,
American Institute of Electrical Engineers.

Gentlemen:

This Committee has counted and canvassed, in accordance with Article VI of the Constitution, the nomination ballots

received for officers of the Institute for 1921-1922. The result is as follows:

Total number of envelopes said to contain ballots, received from the Secretary		2396
Rejected on account of bearing no identifying name on outer envelope	52	
Rejected on account of having reached Secretary's office after February 28	71	
Rejected on account of ballot carrying signature of voter	1	124
Leaving as valid ballots		2272

These valid ballots were counted and the result is shown below:

FOR PRESIDENT

William McClellan	1085
Charles S. Ruffner	995
Scattering and blank	192
Total	2272

FOR VICE-PRESIDENTS

District		
No. 1. North Eastern		
	W. A. Hall	1758
	Scattering	98
No. 2. Middle Eastern		
	J. D. Lyon	423
	N. W. Storer	900
	J. B. Whitehead	570
	Scattering	20
No. 3. New York City		
	W. A. Del Mar	1760
	Scattering	96
No. 4. Southern		
	C. G. Adsit	1717
	Scattering	97
No. 5. Great Lakes		
	J. C. Parker	1130
	R. F. Schuchardt	753
	Scattering	30
No. 6. North Central		
	F. W. Springer	1737
	Scattering	85
No. 7. South West		
	H. W. Eales	1669
	Scattering	100
No. 8. Pacific		
	Robert Sibley	1729
	Scattering	87
No. 9. North West		
	O. B. Coldwell	1724
	Scattering	35
No. 10. Canada		
	F. R. Ewart	897
	Julian C. Smith	863
	Scattering	43

FOR MANAGERS

E. T. J. Brandon	785
G. L. Knight	977
H. P. Liversidge	876
A. G. Pierce	1123
Harlan A. Pratt	946
R. B. Williamson	1103
Scattering	193

FOR TREASURER

George A. Hamilton	1772
Scattering and blank	500
Total	2272

(The scattering vote for each office was divided among several candidates, each of whom received less than 3 per cent of the total vote.)

Respectfully submitted,

E. A. SKEHAN, *Chairman*
H. W. PARSONS
H. B. WIER
JOHN D. POLLOCK
W. M. VERNOR
Committee of Tellers

MANUSCRIPTS FOR THE JOURNAL

In carrying out the policy of the Publication Committee of limiting the number of pages of reading matter in each issue of the JOURNAL in order to keep approximately within the pro rata monthly appropriation, the Editorial Department now has on hand a considerable amount of excellent material worthy of publication, when space and funds are available. At a meeting held February 16, the Publication Committee decided that in order to publish as many papers as possible, on a wide variety of subjects within the field of electrical engineering and the allied sciences, it will be necessary that more attention be paid to condensing the ideas expressed. With this object in view, it was voted to bring the conditions which limit the amount of material that may be published (as outlined above) to the attention of the Meetings and Papers Committee, for the purpose of reminding that committee of the desirability of requiring authors to reduce the length of their papers as far as possible without omitting any essential features, and particularly of omitting any non-essential illustrations as the cost of engraving is one of the large items of publishing the JOURNAL.

INSTITUTE PRIZES

At various times the desirability of establishing prizes to be awarded by the Institute to authors of papers has been discussed.

The subject has again been active recently, and at a meeting of the Committee on Coordination of Institute Activities, the following resolutions were adopted and were approved at the January meeting of the Board of Directors and referred back to the Coordination Committee for the formulation of the necessary details of procedure in making the awards:

RESOLVED, that it is the sense of the Committee on Coordination of Institute Activities that it is desirable for the Institute to award prizes annually to the authors of papers within the field of electrical engineering and of the allied arts and sciences; and we recommend that if this policy be approved by the Board of Directors, the Institute look forward to establishing eventually, say, three prizes in the following classifications: (1) papers prepared by enrolled Students of the Institute and which may have been presented at any meeting of the Institute, a Section, or a Branch; (2) papers prepared by a member of the Institute who has never before presented a paper before the Institute or any of its Sections, and which have been presented at a meeting of a local Section; (3) papers prepared by any member of the Institute and presented before any meeting of the Institute, a Section, or a Branch.

RESOLVED, that this Committee recommends to the Board of Directors that a prize of $100. cash and a suitable certificate be awarded each year to the author of the paper which is designated by a duly authorized committee of award as the most worthy original paper presented during the year at a meeting of any Section of the Institute by a member of the Institute who has never before presented a paper before the Institute or any of its Sections.

Thus it will be seen that all papers presented at meetings of Sections of the Institute during the year 1921 by any member of the Institute who has never before presented a paper before the Institute or any of its Sections are eligible for this competition, which is intended to cover the second classification referred to in the first resolution quoted above.

The Coordination Committee also considered a specific offer from the Jeffery-Dewitt Company to donate to the Institute $100. each year for the purpose of establishing a prize for the best paper on a subject within the field of high-tension transmission and distribution. The Committee recommended that

"the offer of the Jeffery-Dewitt Insulator Company be accepted as applying to an award for the calendar year 1921." The Board approved this recommendation and referred the matter back to the Coordination Committee for the purpose of formulating the necessary plan of procedure.

The details for making the award have not yet been announced, but it may be understood that all papers presented before the Institute during the calendar year 1921 within the field of high-tension transmission and distribution are eligible for this award. The procedure to be followed in connection with the award of these prizes will be published in a later issue of the JOURNAL.

FIRST KELVIN MEDAL AWARD

The first Kelvin Medal has been awarded in 1921 to Dr. W. C. Unwin, F. R. S. This medal was established in 1914 with the provision that it be awarded triennially as a mark of distinction to a person who had reached high eminence as an engineer or investigator in the kind of work applicable to the advancement of engineering with which Lord Kelvin was especially identified. It was afterwards decided to defer the first award until after the termination of the World War. The medal is awarded by a committee consisting of the presidents of the principal representative British Engineering Institutions.

Professor William Cawthorne Unwin, LL. D., F. R. S., by his contributions to physical and engineering science and to the literature of engineering, by his pioneer work in connection with engineering education, his wide learning and great ability in the prosecution of research, his devoted enthusiasm for more than fifty years to a bold and consistent advocacy of the application of scientific methods to the solution of engineering problems, has possibly done more than any other living member of the British Empire to establish modern engineering upon a scientific basis.

AMERICAN ENGINEERING COUNCIL

REPORT OF PATENTS COMMITTEE
Engineers Urged to Aid Patent Bill

March 7, 1921.

The Patents Committee of American Engineering Council urges all engineers to give prompt attention to the following:

The bill for the imperatively necessary relief of the Patent Office, after passing the House of Representatives with satisfactory provisions for the Patent Office, failed to pass the Senate at the session just closed with those same provisions, solely because of the presence in it of an unrelated section known as the Federal Trade Commission Section.

The former opposition in the Senate to the Patent Office relief and that which forced the unacceptable reductions in salaries and numbers of examiners and clerks (which the Conference Committee was persuaded to set aside) is largely and seemingly almost wholly overcome. But the opposition in the Senate to the Federal Trade Section is determined and has expressed an intention to prevent the Patent Office from getting the desired relief, unless the Federal Trade Section is removed from the bill.

More than preventing the Patent Office relief, however, the Federal Trade Section is believed to be a dangerous measure in itself. It provides that the Federal Trade Commission may receive assignments of and adminster inventions and patents from governmental employes and is an entering wedge for further legislation to empower the Trade Commission to receive patents from non-governmental inventors or owners. An exclusive license would have to be granted, at least for a few years, to induce any one to undertake the almost always necessary development expense, and the Trade Commission would surely be charged with favoritism in granting such a license. In order to protect its licenses, the Trade Commission would have to sue infringers, most unfortunate activity for the government. The industries would close their doors to the government employes fearing to disclose to them their secrets or unpatented inventions, and research by the industries would be discouraged for fear that government employes, using government facilities, might reach the result first and patent it. The Trade Commission, owning a large body of patents, in case that one of its patents was found to be infringed during or at the close of a frequently very expensive development by private interests would be able to dictate in the license the price at which the article, which was the object of the development, could be sold, or to dictate other similar conditions, thus depriving the development of much of its value; and could even require the licensee, as a condition for granting needed license, to practically destroy some of its unrelated patents, as by licensing the trade generally when it would prefer to retain the monopoly for itself.

The foregoing and other objections would result in making patents less desirable to own or to purchase, and consequently would decrease the incentive to produce inventions, which production is the main purpose of our patent system.

The proposed section is unnecessary for the protection of government employes, since they now have all the rights which non-governmental employes have to patent inventions and to sell them. It is therefore believed that the Federal Trade Commission section should not be enacted into law in any form, even as a separate bill.

The Patents Committee of American Engineering Council requests that you request every member of each of the constituent societies of The Federated American Engineering Societies immediately to write his representative and his two senators and the Chairmen of the Committees on Patents of the Senate and the House of Representatives (without naming the Chairmen, as it is not now known who they will be) urging them to eliminate the Federal Trade Commission Section from the Nolan Patent Office Bill H. R. 11,984 and prevent such section from becoming a law in any form and to reintroduce at the opening of the special session of Congress to begin April 4th and pass the bill at once.

(Signed) EDWIN J. PRINDLE, Chairman, Patents Comm.
J. PARKE CHANNING, Secretary, Patents Comm.
Approved: L. W. WALLACE, Executive Secretary
American Engineering Council.

COMMITTEE ON ELIMINATION OF WASTE IN INDUSTRY

The Committee on Elimination of Waste in Industry came into existence from a speech in Washington by Mr. Hoover, in November:

> It is primary to mention the three-phase waste in production; first, from intermittent employment; second, from unemployment that arises, in shifting of industrial currents; and third, from strikes and lockouts. Beyond this elimination of waste there is another field of progress in the adoption of measures for positive improvement in production.
>
> In the elimination of the great waste and misery of intermittent employment, we need at once coordination in economical groups.

In an executive meeting of The Federated American Engineering Council, Mr. Hoover further discussed the need for an intensive study being made of all causes for industrial waste, emphasizing those factors that contribute to labor, or manpower waste. He suggested to the American Engineering Council, the governing body of The Federated American Engineering

Societies, the advisability of appointing a committee of fifteen carefully selected engineers to undertake a study of waste in industry.

The American Engineering Council readily consented to the request of Mr. Hoover. He then formed the Committee on the Elimination of Waste in Industry.

In selecting the personnel of this committee, care was exercised to secure men of broad experience, of clear concepts, of unbiased attitude towards labor problems and representative of managerial, consultant, educational and editorial activities as well as having a widely distributed and a varied industrial contact.

At the organization meeting of the committee in January, its purpose was stated to be:

First: Determine the cause of labor, material and equipment waste in industry. The material and equipment phases of the problem to be studied only insofar as they may cause labor waste.

Second: Insofar as possible determine the extent of the waste that arises through each major cause.

Third: Suggest means of removing the cause for such waste.

To accomplish the purpose of the committee, it has been found necessary to make studies along the following lines:

First: Organization—that which assigns responsibilities and relationships and the discharge of same.

Second: Engineering—which comprises the design, construction and maintenance of plant, machinery and tools and the design of the product.

Third: Production Control and Cost Control. Under this division fall all the factors relating directly to production and the proper direction and accounting for the same.

Fourth: Physical Factors. This division relates to the storage and inspection of raw and processed materials and to matters of internal transportation. It also includes consideration of the physical condition of the plant as regards lighting, heating, toilet facilities and such like.

The first and third sections, as well as a major part of the fourth, directly relate to the human element in industry. The committee is devoting the major portion of its effort to the factors that affect the human element.

Industries to be Studied. Ten representative industries have been selected. They were selected because of their general importance and interest to the public. The ten selected are:

1. Bituminous coal	6. Paper
2. Building trades	7. Metal trades
3. Transportation	8. Textiles
4. Men's ready-made clothing	9. Shoes
5. Printing	10. Rubber

From three to ten plants of each selected industry are to be visited by an experienced engineer who will secure the information desired by the committee. A carefully proposed list of questions will be placed in the hands of each field worker. The information obtained by the field investigator is to be supplemented by such authoritative data as may now exist in the form of reports made by reliable parties or agencies. Through this means sufficient information is to be secured as to enable the committee to formulate specific conclusions as to the major causes of industrial waste.

Staff. A small staff is to be maintained at headquarters. This staff plans and directs the work. The field work is to be done by engineering firms. The firms are to be carefully selected for their fitness for the work. For example, the investigation of ready-made clothing was assigned to a firm that has had a large experience in that field. Thus the Committee will obtain the benefit of the experience and knowledge of that firm that has had most intimate contact with a given industry. The firms are doing the work at actual cost to them. All profit is being waived.

All authoritative literature upon each general topic is to be carefully searched and digest made by well qualified firms. The headquarters staff will compile all the data and write the final report. The final report is to be reviewed by the committee as a whole. Every effort is to be made to secure authentic and quantitative information. Care will be exercised to prevent any bias or prejudice to influence any phase of the work.

Progress of work. The work of the committee is well under way. Reports on the first investigation in each industry were made on February 21, carrying out the time schedule set February 7th. At a meeting of the Planning Board held on March 1, further reports were presented and plans made for continuing the investigations more intensively. These reports were uniformly encouraging and there is every reason to believe that the investigation will yield information that will have an important bearing on the nation-wide movement inaugurated by the engineer to eliminate waste in American industry. In New York, New England and Pennsylvania the fuel investigation is practically completed.

CURRENT ENGINEERING TOPICS

MUSCLE SHOALS AIR NITRATES CORPORATION

A bill providing for the incorporation of the Air Nitrates Corporation and other special measures for the development of the power project at Muscle Shoals have received much attention from the last session of Congress.

The Air Nitrates Corporation was the subject of long hearing in the Committee and heated debates on the Senate floor. The debates finally became almost entirely along party lines and economic features became a minor consideration. The bill finally passed the Senate after its opponents had succeeded in inserting a provision that the Corporation must earn 5 per cent each year after its establishment. This is a practical impossibility.

When the bill was referred to the House Military Affairs Committee the chairman announced his intention to hold it over until next session, have extensive hearings and if possible take it out of politics. The American Engineering Council has been invited to appear at these hearings to give testimony upon the technical phases of the question.

Another effort was made to get an appropriation of $10,000,000 under the Sundry Civil Bill for the completion of Wilson Dam at Muscle Shoals. This provision threatened to block the passage of the Sundry Civil Bill but it was finally thrown out and the bill passed without it.

It is contemplated at the Capitol that this legislation will come up next session when final disposition will be more readily obtained.

FEDERAL POWER COMMISSION

It will be recalled that the act creating the Federal Power Commission was signed by President Wilson on the last day of the previous session of Congress and was thus saved the necessity of running the legislative gauntlet again last session. It was signed with the express understanding that it would be amended so as to remove the jurisdiction of the Commission from all waters in existing National parks. A bill making this provision effective has been under consideration in both Houses during all of the last session of Congress and was finally passed and signed by the President. (Senate bill No. 4554.)

Other important bills affecting this measure failed, however. They were S. 4529 and H. R. 15126 which carried provision for increased personnel and salaries for the Commission. These were perhaps the most important measures because without their enactment into law, the work of the Commission will be greatly curtailed. It is hoped, however, that they can be brought up for early consideration in the next session of Congress. The House bill has already been favorably reported by the House Committee on Interstate and Foreign Commerce. There is apparently little opposition to it in the House although some

senators are definitely known to be opposed to any extension of the power of the Commission.

At its meeting on February 28, the Commission approved modifications of Regulations Nos. 1-10 which had previously been issued on September 3, 1920, and covered the following subjects:

1. Definition of Terms
2. Applications (General Requirements)
3. Applications for Preliminary Permits
4. Applications for Licenses, Major Projects
5. Applications for Licenses, Minor Projects
6. Applications for Licenses, Major Projects already constructed
7. Declarations of Intention
8. Priorities and Preferences
9. Permits
10. Licenses

It also approved additional regulations 11-20 inclusive covering the following subjects:

11. General Consideration Affecting Approval
12. Project Work
13. Lands Reserved or Classified as Power Sites
14. Annual Charges
15. Benefits from Headwater Improvements
16. Depreciation Reserves
17. Amortization Reserves
18. Expropriation of Excessive Profits
19. Allocation of Earnings
20. Accounts and Reports

These regulations were adopted after four hearings had been held and many modifications made. Many of the recommendations made by the Water Conservation Committee of Engineering Council were embodied in these regulations. These regulations as finally approved were ready for distribution shortly after the middle of March.

One of the last acts of the old Commission which was composed of the outgoing Secretary of War, Interior and Agriculture was to approve and authorize the issue of five preliminary permits, four licenses for complete projects and five licenses for transmission lines.

Nearly 200 applications for permits and licenses have been received by the Commission. These applications cover over 13,000,000 horse power and have come from every section of the country.

PERSONNEL RESEARCH FEDERATION

Under the auspices of the National Research Council and Engineering Foundation, in the building of the National Research Council, Washington, was effected March 15th, the organization of the Personnel Research Federation. This Federation includes in its membership scientific, engineering, labor, management and educational bodies. The Personnel Research Federation has been organized to bring about interchange of research information among the numerous organizations which are engaged in personnel research. It is reported to the new Federation by the Bureau of Labor Statistics, of the Department of Labor, that there are 250 such organizations in the United States. The Personnel Research Federation will collect research information, will encourage research through individuals and organizations and will coordinate research activities.

Temporary officers were elected as follows:

Chairman—Robert M. Yerkes, representing National Research Council.

Vice-Chairman—Samuel Gompers, representing American Federation of Labor.

Treasurer—Robert W. Bruere, representing Bureau of Industrial Research.

Secretary—Alfred D. Flinn, representing Engineering Foundation.

Acting Director—Beardsley Ruml, assistant to the president of Carnegie Corporation of New York.

The aims of the new organization are increased efficiency of all the personnel elements of industry—employer, manager, worker—and improved safety, health, comfort and relationships.

The immediate purposes of the Personnel Research Federation will be to learn what organizations are studying one or more problems relating to personnel and the scope of their endeavors, and to determine whether these endeavors can be harmonized, duplication minimized, neglected phases of the problems considered, and advanced work undertaken.

November 12, 1920, a preliminary conference was held in Washington under the auspices of National Research Council and Engineering Foundation, attended by forty persons, including representatives of national organizations of scientists, engineers, labor, capital, managers, educators, economists and sociologists. The question under discussion was the practicability of bringing about cooperation among the many bodies conducting research relating to men and women in industry and commerce, from management to unskilled labor. Such topics as the relations of persons doing different parts of the work, and the influence of working conditions upon the health, output and happiness of the workers, are examples of those which could be made subjects of research.

Dr. James R. Angell, Past-Chairman of the National Research Council, in an address to the conference summarized in the following words the kinds of problems which should receive attention from the organization then proposed:

> Certain of the hygenic problems of modern industry exemplify cases in which a thoroughly scientific study of causes and effects is possible with convincing conclusions regarding practise which will safeguard the health and vigor of all concerned. Not a few highly important results have already been attained in this field. The effects upon industrial productivity on the one hand, and physical vitality, on the other, of good and bad ventilation, of good and bad light, of high temperatures, of irritant fumes, of dust and other similar features are, theoretically, at least, within the field of scientific analysis, and the ascertainment of demonstrable fact. Similarly, and in a different zone of inquiry, it should be possible to secure thoroughly reliable data regarding the dominant causes of unrest in our industries, of excessive turnover and the like. Many other instances of the same kind will suggest themselves to all who have experience in the industrial field.

The underlying ideas which led to the conference, were (1) the advantages of studying such questions by the scientific method of gathering facts and using them to reach conclusions instead of discussing opinions and propaganda, and (2) the need for cooperation among the organizations and individuals engaged in such studies.

FUNCTIONS AND SCOPE OF THE FEDERATION

1. Collection and dissemination of information through:
   (a) Registration of researches contemplated, in progress, or completed;
   (b) Collection of research information;
   (c) Cataloging and analyzing the research information;
   (d) Collecting and analyzing of methods of instruction and training for personnel work;
   (e) Publication;
   (f) Publicity;
   (g) Consultation and advice, when requested.
2. Stimulation and initiation of research through individuals, organizations and governmental agencies, by:
   (a) Publicity and correspondence;
   (b) Personal contact with research agencies;
   (c) Advice and encouragement in the formation of necessary new agencies,
   (d) Aiding governmental agencies to secure appropriations necessary for them adequately to carry on personnel and employment work;
   (e) Calling special conferences;
   (f) Definition of problems needing investigation.
3. Coordination of research activities through:
   (a) Regular meetings of representatives of cooperating agencies;
   (b) Regular reports of affiliated agencies on work in progress and completed;
   (c) Correspondence and personal consultation.

The Personnel Research Federation is beginning modestly and will extend its efforts as it gains in number of members and in financial support. It does not propose to undertake at the beginning all the functions outlined. The Federation is not another agency for research, but rather a clearing house for the existing agencies.

AMERICAN ENGINEERING STANDARDS COMMITTEE

COPPER SPECIFICATIONS SUBMITTED FOR APPROVAL

The American Society for Testing Materials has submitted the following copper specifications to the American Engineering Standards Committee for approval:

Specifications for Soft or Annealed Copper Wire (B3-15)

Specifications for Lake Copper Wire Bars, Cakes, Slabs, Billets, Ingots and Ingot Bars (B4-13)

Specifications for Electrolytic Copper Wire Bars, Cakes, Slabs, Billets, Ingots and Ingot Bars (B5-13)

Methods for Battery Assay of Copper (B34-20)

The specifications are submitted in accordance with the special provision in the procedure of the Committee, under which important standards in existence prior to 1920 may be approved without going through the regular process followed in new work.

The Committee would be very glad to learn from those interested of the extent to which they make use of these specifications, and to receive any other information regarding the specifications in meeting the needs of the industry.

Specifications B3-15, B4-13 and B5-12 may be found in the 1918 volume and Specifications B34-20, in the 1920 volume, of A. S. T. M. Standards. Copies of these may also be obtained from the American Engineering Standards Committee, 29 West 39th Street, New York. Price 25 cents each.

NATIONAL RESEARCH COUNCIL

BENEFITS DERIVED FROM RESEARCH

In order to carry out the function of stimulating industries to conduct research work, the regular meeting of the Division of Engineering, Friday evening, February 4, 1921. was largely given over to two speakers, Dr. Charles L. Reese, Chemical Director of E. I. du Pont de Nemours and Company, and Mr. A. J. Wadhams, General Superintendent of the International Nickel Company, Orford Works.

Dr. Reese brought out very strikingly the enormous advantages derived by his company from research work. The benefits from one research alone were more than sufficient to pay the expenses of the Research Laboratory for a number of years. Aside from monetary gains Dr. Reese pointed out that the research work of his company (a) resulted in increased safety of employees, (b) enabled the company to keep ahead of the art (c) reduced selling prices of established products in spite of increased cost of labor and raw materials (d) increased output (e) discovered new products, the benefits of which often added to the safety, comfort and happiness of the people of the country (f) conserved materials, (g) advanced the art in a few years equivalent to fifty years of normal experience. Disregarding those benefits which cannot be figured into dollars and cents, which are extremely important, there results to his company in a few years a saving or gain of $84,401,000 against an expenditure of $6,051,000 for research work during this period. (A profit of several times the gain quoted will eventually result from continued manufacture of these products without additional expense for research work.)

Mr. Wadhams talked on research work from an operating man's point of view. He pointed out the difficulties of the research man in the factory where all sorts of "hurdles" were placed for him to jump. In spite of these difficulties, the research man was slowly convincing the practical foreman and superintendent of the value of his work by reduced costs, increased outputs, and improvement of quality. His mission of education is not limited to this task, however, as in a great many cases it is just as hard to capitalize the research laboratory in the eyes of the Board of Directors and convince them of the benefits derived therefrom.

It is interesting to note that a large part of the profits that result from research accrue ultimately to the benefit of the consumer in reduced prices.

Future meetings of the Division will be largely given over to distinguished speakers from other industries, who will deal with the general subject of the benefits derived from research work. Executives of corporations who might advantageously be interested to follow these worthy examples, will be invited to attend these meetings.

ENGINEERING FOUNDATION

ANNUAL REPORT FOR SIXTH YEAR

Following are excerpts from the annual report of the chairman of the Engineering Foundation of United Engineering Society for the year ending February 10, 1921:

Sixth Year

Engineering Foundation has been developing methods and means for accomplishing the purposes for which it was created, "the furtherance of research in science and in engineering and the advancement of the profession of engineering and the good of mankind." Its present limited resources have been most effectively employed in demonstrating the value of certain researches and thus attracting from the interested industries support for the further conduct of such researches. The noteworthy example for the year under review is the investigation of the Fatigue Phenomena of Metals.

Endowment Increase

By letter of October 25, 1920, Ambrose Swasey, of Cleveland, Ohio, added two hundred thousand dollars to his gifts to United Engineering Society for endowment of Engineering Foundation, making the total a half-million dollars. He also gave the income of the new fund from January, 1920.

At the beginning of the year, the Board was faced with a possible deficit of $16,000 by 1922, in carrying out its undertakings with the National Research Council, but Edward Dean Adams, of New York, generously assumed this contingent liability. The financial requirements for the work in hand having been provided by the increased income from endowment, the assumption of contingent liability by Mr. Adams was canceled.

Further increase of endowment has been sought. Many friends of the Foundation have helped. Letters have been exchanged and interviews had with men of large wealth in many parts of our country. Some encouragement has been received. One friend offered to give $50,000 if nine other men would make equal gifts.

Forms for Deed of Gift and Declaration of Trust, after study for more than a year, were adopted December 10, and approved by the Trustees December 21, in accordance with a report by Mr. Edward Dean Adams, prepared with the cooperation of Parker and Aaron, Counsel to United Engineering Society.

Progress on Work in Hand

Study was given to policy as to patents secured in connection with the work of Engineering Foundation, and to standard forms for use in connection with grants of assistance for research projects. A number of important letters on patent policy have been collected and filed. Conclusions have not been reached by the committee, although good progress has been made.

Close relations with National Research Council were continued. Increasing cooperation has been given by the Founder Societies. Other technical societies also have shown appreciation for Engineering Foundation and aided in making its work and needs known.

The Fatigue Phenomena of Metals Research has progressed

at the Engineering Experiment Station of the University of Illinois. Interesting partial results have been secured. Attracted by the facilities created by the financial support of the Foundation and the cooperation of the Division of Engineering of National Research Council with the University of Illinois, the General Electric Company entered into an agreement for an extension of the program to cover nickel steels of special interest to it. For this purpose, the company is contributing $30,000, thus duplicating the grant of the Foundation. It has been reported that other industrial corporations are considering similar action.

Engineering Foundation, the Founder Societies and other technical organizations, together with Federal and State governments, cooperated with the Division of Engineering in establishing an Advisory Board on Highway Research.

An Hydraulic Research Committee has collected information about all important known hydraulic laboratories in our country. From this material, a bulletin is being prepared for publication at an early date.

Dr. E. E. Southard was aided by a small grant in the study of Mental Hygiene of Industry, but his work was stopped in its preliminary stages by his sudden death in February, 1920. An offer from Harvard Medical School to cooperate in resuming these studies was regretfully declined for lack of funds.

Engineering Foundation cooperated with National Research Council in examining the possibilities of bringing about useful cooperation in Industrial Personnel Research.*

Hydraulic Weir Tests conducted at the laboratory of Massachusetts Institute of Technology, Cambridge, by Mr. Clemens Herschel with the aid of funds from Engineering Foundation, produced a new form of weir and a very simple formula for determining the quantity of liquid flowing over the weir. The experiments and results are described in a report submitted by Mr. Herschel in March, 1920. There have been many demands for this Reprint No. 4, not only from all parts of North America, but also from South America, Europe and Asia.

Tests on Wear of Gears were resumed during the summer, at Leland Stanford Junior University, by Professors Guido H. Marx and Lawrence E. Cutter. One set of tests was completed, yielding useful, but, of course, limited results.

New Projects

On the suggestion of the American Society of Mechanical Engineers, there was appointed at the December meeting of the Foundation a committee on Industrial Education and Training to examine the practicability and desirability of an extended investigation of the education and training of men for and in the industries. Sources of funds for this work were indicated. This committee has presented a preliminary report with recommendations for the next steps in the formulation of the problem.

January 4, 1921, a formal application for aid in an investigation of Permanent Magnetism was made by L. M. Dieterich, of New York, for the purpose of establishing principles relating to a novel prime mover. This application is under consideration, and meanwhile, Mr. Dieterich is discussing his fundamental theory with several well-known physicists.

Applications were also made by Cyrus Prosch, of New Jersey, for investigating an improvement in steam engineering for the conservation of coal; by Arthur Pestel, of New York, for investigating a theory of the transmutation of energy; and by F. W. Dean, of Pennsylvania, for extension of tests of efficiency of a unaflow engine and of a marine boiler. These applications were severally declined for various reasons.

The Chairman of the Division of Engineering of National Research Council and other persons have suggested that if funds could be provided specific researches in the following broad fields might be supported by Engineering Foundation, with great advantage to the profession and the industries:

1. Cryogenics, particularly research in characteristics of gas mixtures in relation to liquefaction and separation of gases for industrial purposes.
2. Electrical insulation.
3. Colloidal lubricants and fundamental principles of lubrication.
4. Fundamental study of laws of crystallization of metals, atomic structures and other metallurgical problems.
5. Improvement of utilization of all kinds of fuels.
6. Principles of heat transfer.
7. Landslides and earth pressures.
8. Ceramics.
9. Hydraulics.
10. Industrial education and training.
11. Social industrial engineering.

Some investigations have been made and others are being made in these fields, but much important work remains to be done.

Publications and Publicity

During the year, Engineering Foundation published four pamphlets, being "Reprints" of reports made to it and printed in technical journals.

Publicity for the work and needs of Engineering Foundation has been extended by an engagement, beginning November 1, with Mr. James T. Grady, Director of the Department of Public Information, of Columbia University.

Meetings and Membership

Four regular and two special meetings were held during the year. The meeting on December 10 was preceded by a dinner to Mr. Swasey, at which an engrossed certificate was presented expressing appreciation of his gifts.

Two members of the board died during the year: Edmund Gybbon Spilsbury on May 28, and Dr. Samuel Sheldon on September 5.

A financial statement is appended.

Respectfully,

CHARLES F. RAND,
Chairman.

Financial Statement

FOR YEAR ENDED DECEMBER 31, 1920

The Engineering Foundation Board administers the income from an endowment fund now amounting to $500,000, presented to the United Engineering Society.

CASH RECEIPTS AND PAYMENTS

Funds on hand January 1, 1920:		
Cash in bank	$9,591.42	
U. S. Treasury Certificates	10,000.00	
Total		$19,591.42
RECEIPTS:		
Interest on $500,000 bonds held by United Engineering Society (less collection, custodial and advisory charges)		24,069.76
Interest on daily bank balances		159.68
Interest on U. S. Treasury Certificates		224.25
Total		$44,045.11
PAYMENTS:		
Salaries (Secretary and office force)	$5,063.81	
Miscellaneous office expenses	284.08	
Stationery and printing	295.62	
Traveling expenses	163.04	
Publications	1,801.16	
Publicity	500.00	
Mental Hygiene of Industry research, balance	1,108.70	
Hydraulic Weir Tests, balance	60.47	
Division of Engineering, N. R. C. (office rental and part of salary roll)	8,676.47	
Fatigue Phenomena of Metals research	10,000.00	
Total		$27,953.35
Balance on hand December 31, 1920		$16,091.76

ASSETS AND LIABILITIES

ASSETS:	
Cash in bank December 31, 1920	$1,045.51
Petty cash	15.00
U. S. Treasury Certificates	15,031.25
Total	$16,091.76

LIABILITIES:

Apart from salaries and other routine expenses, the only liabilities of Engineering Foundation are the unexpended balances of appropriations for researches: For Gear Tests, $207.73; for Fatigue Phenomena of Metals, $11,000.

*See PERSONNEL RESEARCH FEDERATION, p. 347 of this issue.

Publications

Publications are issued in two series, in the standard size for scientific societies (7 x 10 inches).

PUBLICATIONS

No. 1. Report on the Origin, Foundation and Scope of the National Research Council, February, 1917.

No. 2. A Progress Report to United Engineering Society, October, 1919.

No. 3. Annual Report for Year ended February 10, 1921.

No. 4. Hydraulic Laboratories in U. S. (In preparation.)

REPRINTS

No. 1. The Mental Hygiene of Industry, March, 1920; from "Industrial Management," February, 1920. Out of print.

No. 2. Trade-Unionism and Temperament, April, 1920; from "Industrial Management," April, 1920. Price, 25 cents.

No. 3. The Modern Specialist in Unrest, June, 1920; from "Industrial Management," June, 1920. Price, 25 cents.

No. 4. An Improved Form of Weir for Gaging in Open Channels, May, 1920; from "American Society of Mechanical Engineers," June, 1920. Price, 35 cents.

RESEARCH NARRATIVES

In January, 1921, the semi-monthly publication was begun of a series of leaflets each containing the story of some research or discovery or notable achievement in science or engineering, very briefly told. There have been printed to date:

No. 1. Isolated Research—Its Handicaps: The Story of Mendelism.

No. 2. Fatigue of Metals: A Story of Cooperation.

No. 3. Utilizing Low-Grade Ores: An Iron Story.

No. 4. Electric Welding: From Lecture Room to Industry.

No. 5. Early Uses of Nickel.

Complete copies of this report may be obtained by addressing Engineering Foundation, 29 West 39th Street, New York, N. Y.

MARINE RULES

RECOMMENDED PRACTISE FOR ELECTRICAL INSTALLATIONS ON SHIPBOARD

The differences between the requirements of various Classification Societies and Insurance Companies in regard to electrical installations on shipboard and the lack of any accepted standard engineering practise for marine installations led the American Institute of Electrical Engineers in 1913 to appoint a Committee on the use of Electricity in Marine Work, now known as the Marine Committee. This Committee besides arranging for papers to be read at the meetings of the Institute to increase the interest of Electrical Engineers in marine problems, also took up the preparation of the Standardization Rules which would represent good engineering practise, and which might be accepted by the Classification Societies. As a result, a set of rules was prepared covering two important divisions; namely Fire Protection Requirements, and Marine Construction Requirements. The first part related primarily to dangers that might arise from fires, and the second part had to do purely with the preservation, maintenance and operation of the electrical plant in its exposure to the conditions existing on shipboard.

These rules were adopted by the Committee of the American Bureau of Shipping and were published as Section 37 of the Rules for building and classing vessels, issued by that Bureau.

This first edition of the Rules did not cover the entire field of the use of electricity on shipboard, and the Committee was, therefore, continued in force, and a more nearly complete Set of Marine Rules has now been prepared. The Committee has made a careful comparison of the Rules issued by the American Bureau of Shipping, the National Board of Fire Underwriters, the Steam Boat Inspection Service of the U. S. Department of Commerce, Lloyd's Register of Shipping, the Institution of Electrical Engineers, Bureau Veritas, Germanischer Lloyd, and Verband Deutscher Elektrotechniker. With several of these Associations, correspondence and personal conferences were carried on.

When the Committee had nearly completed its work on the second Set of Marine Rules, the Regulations for the Electrical Equipment of Ships, First Edition, were issued by the Institution of Electrical Engineers in England. These Rules have substantially the same scope as those prepared by the American Committee, and as there will be some occasion for comparing the engineering practises of the two countries, a slight rearrangement of material has been made to conform more nearly to the order of subjects as given in the English Rules, in order to facilitate comparison.

In the preparation of these rules, consideration has been given to the danger from fire, and to durability and reliability of the electrical apparatus itself, but no attempt has been made to divide the Rules into separate sections of that character.

Certain Mechanical Signaling Systems are included, as it is the custom of many shipyard electrical engineers to supervise the installation of mechanical signaling equipments as well as the electric plant.

The membership of the Committee being drawn from a large variety of shipbuilding, manufacturing and engineering interests, including the U. S. Navy, it is thought that the Rules, as prepared, represent the best practise for this class of work. During the War, a large number of the newer shipyards were represented on the Marine Committee, which gave opportunity for advising them, through the Committee Meetings concerning the best engineering practise as followed by the older yards.

To insure a careful consideration of these Rules sub-committees were appointed to cover various branches of the work, and after each sub-committee had considered its own rules, they were submitted for discussion to the entire Committee, after which they were referred to an Editing Committee of four members to arrange them in suitable form for publication. It is not to be expected that this edition of the Rules contains everything that might be of value relating to electrical installations on shipboard, and it is expected that later editions will be prepared which will be more complete and will include electric propulsion.

In the meantime, any questions concerning Rules, which appear to be of doubtful meaning, may be referred to the Chairman of the Marine Committee of the American Institute of Electrical Engineers, 33 West 39th Street, New York City, and the Committee invites suggestions for improvements or amplifications of these Rules.

No definite arrangements have yet been made for the approval of apparatus and accessories, but it is expected that through the cooperation of the Underwriter's Laboratories, arrangements will be made later by which apparatus or appliances used on shipboard may be inspected and approved.

In the absence of approved standards for Merchant Ships, appliances approved by the Navy Department will in general be satisfactory.

Bound copies of the Rules may be obtained at $1.00 per copy by addressing American Institute of Electrical Engineers, 33 West 39th Street, New York, N. Y.

INSTITUTE YEAR BOOK

The A. I. E. E. 1921 Year Book is available to members, without charge, upon application to the Secretary, 33 West Thirty-ninth Street, New York.

The book contains an alphabetical and geographical catalog of the membership revised to January 1, 1921; also the constitution, by-laws, lists of officers and committees, and considerable additional information relating to the activities of the INSTITUTE.

STANDARDIZATION OF LIGHTING FIXTURES

At a meeting of the Council of the Illuminating Engineering Society held on March 10, 1921 the following resolution was adopted:

Whereas in the opinion of the Council of the Illuminating Engineering Society the project for rendering lighting fixtures readily removable by the employment of suitable electric attachments as discussed at the January meeting of the New York Section of this Society, offers potentiality for large improvement in lighting conditions, and

Whereas realization of the potential value of this project is contingent upon such standardization as will make the electric attachments of fixtures completely interchangeable, and

Whereas failure to so standardize attachments would jeopardize the success of the project entailing untold inconvenience and confusion to the public, be it therefore

Resolved that in the best interest of the public and of the lighting industry the Council hereby urge all concerned to cooperate to the fullest extent in bringing about complete interchangeability of removable lighting fixtures.

PERSONAL MENTION

P. E. Klopsteg is leaving the Leeds & Northrup Company to go with the Central Scientific Company of Chicago.

A. A. King has accepted a position as chief electrician with the Phelps-Dodge Corporation, Copper Queen Branch, Mines Department, Bisbee, Ariz.

George Sutherland has changed from Stone & Webster, Inc., Boston, to the United Electric Light & Power Company, New York.

Wallace B. Kirke has left the General Electric Company to become assistant to the chief electrical engineer of the New York Edison Company.

John H. Bell, telegraph engineer with the Western Electric Company, New York, has returned from London, where he has been for several months on a business trip.

H. C. Wolf, formerly with Arthur Young & Co., Chicago, is now assistant chief engineer with the Public Service Commission of Maryland, Baltimore, Md.

H. E. Driver of the Westinghouse Electric & Manufacturing Co., Chicago, has returned from France and may now be reached at his former address, 32 S. Peoria St., Chicago.

Frederick A. Kolster has changed from the Bureau of Standards, Washington, D. C., to the Federal Telegraph Co., Palo Alto, Cal.

Lee R. Titcomb has left the employ of the Klaxon Company, Newark, N. J., and has engaged in research and consulting work on his own accord, with headquarters at 26 Fulton Street, Bloomfield, N. J.

Harold S. Hughes, electrical contractor, who has been connected with the Camp Signal Office at Camp Funston, Kansas, is now at West Point, N. Y. His address is Box 90, West Point, N. Y.

S. Reyes of Brooklyn, N. Y., and of the Bureau of Insular Affairs, Washington, D. C., sailed on March 1st for the Philippine Islands. His address there will be Bureau of Posts, Manila, P. I.

J. L. McK. Yardley, formerly chief engineer of The Beaver Board Companies, Buffalo, N. Y., resumed association January 1st, 1921, with the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., as general engineer.

George K. Whitworth has severed his connections with the Bethlehem Shipbuilding Corporation of San Francisco, and does not expect to be identified with any firm for the next two years, as he will give his entire time to further studies in engineering. His address is 2415 Bowditch St., Berkeley, Cal.

Ira Dye has given up his position as superintendent of the American Frog and Switch Co., at Hamilton, Ohio, and has opened an office at 430 Lumber Exchange, Seattle, Washington, for the practise of Industrial Engineering in the Puget Sound District.

S. N. Clarkson has resigned from the editorial staff of the *Electrical World* and has opened an office as consulting engineer in the Star Building, St. Louis. Mr. Clarkson will specialize on Public Utility rate matters, public relations and the problems involved in financing and supplying service to rural consumers of electric service.

Charles N. Arnold has been appointed as instructor in Mechanical Engineering in the College of Engineering of the University of Illinois. Mr. Arnold was graduated from the University of Illinois in 1911, after which he worked with several electrical companies, being assistant chief electrician for Armour and Company, 1915-1917; and during the war served as lieutenant in the U. S. Navy on engineering duty.

James W. Owens delivered a lecture on March 18th to the commissioned and civilian technical force of the Bureau of Construction and Repair of the Navy in Washington, D. C., on "The Use of Welding in Ship Construction." For the past three years Mr. Owen has been engaged in extensive research on welding at the Norfolk Yard for this bureau, and supervised the construction of Battle Towing Target No. 60, America's largest welded structure. (A description of this target may be found in *The Welding Engineer* for December, 1920.)

Walter C. Strunk has tendered his resignation in the Mechanical Research & Construction Division of the Motive Power Department of the Interborough Rapid Transit Company, New York, to accept a position in the Stoker Division of the Westinghouse Electric & Manufacturing Company, Lester, Pa. Mr. Strunk started work in 1909 with the Metropolitan Street Railway Company, New York, in the Training School for College Men. After spending two years in the school he entered the electrical department. Since 1912, when the New York Railways Company was reorganized, he has been with the Interborough Rapid Transit Co.

C. G. Young has organized the C. G. Young Company, Inc., consulting engineers, located at 501 Fifth Avenue, New York. Mr. Young, a Fellow of the Institute, has had over thirty years' experience in domestic and foreign fields, covering a wide range of engineering construction. He was for seventeen years with the firm of J. G. White & Co. of New York and London. His extensive traveling on engineering and financial business undertakings has covered practically the entire world; and besides being an authority on electric railways and other electrical construction, he is a specialist on financial examination and reports.

OBITUARY

Francis Robbins Upton, former associate of Thomas A. Edison and first President of the Edison Pioneers, men who worked with Mr. Edison in the early days of the inventor's great successes, died Wednesday, March 10th, 1921, at his home in Orange, N. J., following a lengthy illness.

Mr. Upton, who was a mathematician, assisted Mr. Edison in working out complicated problems as to economy and adaptability of the devices necessary to make a complete system of electric light by incandescence. He was also associated with Mr. Edison in his ore milling and subsequently was interested in quarries and in selling materials for concrete construction.

Mr. Upton was born in Peabody, Mass., July 26th, 1852 and was educated in Phillips Academy, Andover, Chauncey Hall, Boston, Bowdoin College, Princeton Univeristy and Berlin University. He was for many years a member of the Institute and served as Vice President 1889-90 and as Manager 1890-92.

Mr. Upton was twice married. His first wife was Mrs. Elizabeth Fenno Perry. He subsequently married Margaret Adriance Storm, who survives him. The surviving children are Elizabeth Fenno, Curtis Perry, Francis Robbins, Jr., Lucina Eleanor Stuart, one son Frederick Thompson.

George Holt Lukes, general superintendent of the Public Service Company of Northern Illinois, with office in Chicago, died February 18, 1921. Mr. Lukes was born in Racine, Wis., December 6, 1869. He was graduated from the Massachusetts Institute of Technology in 1892, after which he took a short student engineering course at the works of the General Electric Company in Schenectady, and then secured employment with the old Chicago Edison Company as inspector. He became night operating superintendent of this company in 1898. He left the Edison Company in 1902 to become superintendent of the North Shore Electric Company; and when the North Shore and several other public utility companies were combined into the present Public Service Company of Northern Illinois in 1911 he was appointed general superintendent of the new company. Mr. Lukes made his home at the Evanston University Club. He took interest in many subjects, though engineering, especially public utility development, remained his life work. Besides belonging to the Institute, he was a member of the Western Society of Engineers, Illuminating Engineering Society, National Electric Light Association, Chicago Engineers Club, Electric Club of Chicago, University Club of Chicago, Evanston University Club, Glenview Golf Club and Park Lodge No. 833, A. F. & A. M. He was also a life member of the Art Institute of Chicago and a sustaining member of the Chicago Society of Etchers.

Frank A. Pickernell, for many years on the engineering staff of the American Telephone and Telegraph Co., died on February 12, 1921, at his residence in Englewood, N. J. Mr. Pickernell was born in Boston, March 28, 1865, and received his engineering education at the Massachusetts Institute of Technology. He then entered the employ of the American Bell Telephone Co. In 1887 he came to New York as superintendent of equipment for the American Telephone and Telegraph Co., and later played an important part in the opening up of the first long-distance line between New York and Chicago. He retired from active business about two years ago. Mr. Pickernell was one of the early members of the Institute, which he joined in 1890. He was also a member of the Telephone Pioneers of America.

Cecil P. Poole died in Norfolk, Va., on February 23, 1921, where he had gone to reestablish his practise as consulting engineer. Mr. Poole was born in Elizabeth City, N. C., October 16, 1863, and received a high school education, acquiring his later technical knowledge by engineering work and by wide reading. His practical work began with the old Brush arc lighting station at Norfolk, in 1884. Three years later he took charge of the lighting and power plant at Lynchburg, Va., and continued to operate it on his own account under lease after he started contracting engineering, in 1888. In 1895 Mr. Poole became associate editor of the *Electrical World*, and for several years devoted his time to technical writing and editing, becoming editor of the *American Electrician* in 1900. He resumed his engineering work, however, and in 1912 moved to Atlanta, Ga., where he later became identified with the engineering department of the city, being in charge of work of the department of inspection. Mr. Poole was a Fellow of the Institute. The members of the Atlanta Sections of the A. I. E. E. and the A. S. M. E. issued a testimonial in memory of Mr. Poole, with whom they were closely associated during many of the last years of his life.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES FEB 1-28, 1921

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

The Airplane

By Frederick Bedell. N. Y., D. Van Nostrand Co., 1920. 257 pp., front., diagrams, 9 x 6 in. cloth. $3.00.

The first six chapters of this volume contain, in revised form, the material previously published under the titles "Airplane Characteristics" and "The Air Propellor." Seven additional chapters discuss problems of flight, performance and stability. The author's aim has been to present a well-rounded introductory treatment simple in form but reasonably complete and accurate.

American Lubricants from the Standpoint of the Consumer.

By L. B. Lockhart. Second edition, revised and enlarged. Easton, Pa., The Chemical Publishing Co., 1920. 341 pp., illus., tables, 9 x 6 in. cloth. $4.00.

This book is offered to buyers and users of lubricants as an aid in the intelligent selection of oils and greases. It describes the various commercial lubricants, explains the laws of friction, the conditions met in lubricating various classes of machinery and the methods used to satisfy them. Methods for chemical and physical tests are given, and specifications for oils and other lubricants for a greater variety of purposes.

Anlagen zur Gewinnung Von Naturlichen und Kunstlichem Grundwasser.

By Paul Brinkhaus. Munchen and Berlin, R. Oldenbourg, 1920. (Oldenbourg's Technische Handbibliothek, bd. 23) 14 + 227 pp., diagrams, illus., charts, 8 x 5 in., cloth. 20M.

The author differentiates his book from others on the utilization of ground water supplies by the omission of descriptions

of existing works for this purpose, which are of historical rather than practical interest. The present volume deals with practical matters only. The exploration and measurement of ground water supplies, the digging and driving of wells and infiltration galleries, are discussed in detail. The book is intended for young engineers.

APPLIED COLLOID CHEMISTRY; GENERAL THEORY.

By Wilder D. Bancroft. First Edition, N. Y. and Lond., McGraw-Hill Book Co. Inc., 1921. (International chemical series.) 345 pp., illus., 8 x 6 in., cloth. $3.00.

Professor Bancroft here presents the theory of colloids, as an introduction to the study of its application in specific branches of industry. The book discusses absorption, surface tension, coalescence, the preparation and properties of colloidal solutions, jellies and gelatinous precipitates, emulsions, foams, non-aqueous colloidal solutions, fog, smoke, etc.

ASPHALTS AND ALLIED SUBSTANCES.

By Herbert Abraham. Second edition, corrected. N. Y., D. Van Nostrand Company, 1920. 608 pp., illus., diagrams, tables, 9 x 6 in., cloth. $6.00.

This is a comprehensive treatise for makers, sellers and users of asphalts, tars, pitches and their products. It includes the methods used for testing and analyzing raw and manufactured products, information on blending and compounding mixtures, general information on the scope of the use of bituminous materials and on their limitations, and the principles underlying the use of bituminous products for structural purposes. Topics which have been adequately presented in other books have been purposely subordinated to those concerning which little has hitherto been published.

CAMS, ELEMENTARY AND ADVANCED

By Franklin De Ronde Furman. N. Y., John Wiley & Sons, Inc., Lond., Chapman & Hall, Ltd., 1921. 234 pp., diagrams, 9 x 6 in. cloth. $3.00.

The first five sections of this book appeared previously under the title "Elementary Cams." To these sections three have been added giving a further development of the subject. The elementary portion gives a classification, an arrangement and a general method of solution of the well-known cams, and also a series of cam factors for base curves in common use. The advanced portion includes the development or use of the logarithmic, cube, circular, tangential and involute base curves, and the establishment of cam factors for those which have general ones.

THE CHEMISTRY OF PLANT LIFE.

By Roscoe W. Thatcher. First edition. N. Y. and Lond., McGraw-Hill Book Co., 1921. (Agricultural and biological publications.) 268 pp., 9 x 6 in. cloth. $3.00

An account of our knowledge of the chemical changes by which the plant cell performs the processes which result in the production of so many substances which are vital to the comfort and pleasure of man. It is intended as a text or reference book, and presupposes an elementary knowledge of chemistry.

COAL WASHING.

By Ernest Prochaska. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 382 pp., illus., diagrams, 8 x 6 in. cloth. $4.00.

In preparing this compendium the author has had in mind the need of the coal operator for a systematic description of modern practise in the art of coal washing. The book opens with a description of the evolution of methods and machines from the beginning. The second and more important section deals in detail with the methods in use today.

CONNECTING INDUCTION MOTORS.

By A. M. Dudley. First edition, N. Y., and Lond., McGraw-Hill Book Co., Inc., 1921. 252 pp., illus., diagrams, 9 x 6 in., cloth. $2.50.

Although the theory of the induction motor has been treated very completely, little has been published concerning the practical details, of which the windings are a prominent part. This work, by an engineer with extensive experience, is for those engaged in operating and repairing these motors. It explains the methods for figuring new windings for old core, locating faults in windings, changing windings to meet varying conditions of voltage and phase, and similar needs which arise.

DIRECT-CURRENT ARMATURE WINDINGS.

By W. E. Henning. First edition. Milwaukee, C. N. Caspar Co. (Practical Electrician Course.) 204 pp., illus., diagrams, tables, 10 x 7 in., cloth. $4.00.

The author states that his object has been to collect practically all of the direct-current armature winding diagrams now scattered through many books, and to present the subject clearly and practically. Mathematical and technical discussions have been simplified and shortened.

ELECTROLYTIC DEPOSITION AND HYDROMETALLURGY OF ZINC.

By Oliver C. Ralston. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 201 pp., front., illus., diagrams, charts, 9 x 6 in., cloth. $3.00.

The author states that while hydrometallurgic zinc processes have scarcely been sufficiently developed to justify an extensive treatise, they are sufficiently standardized to call for a simple text which will set forth present practise and the underlying theory of leaching, purification and electrolysis. This book gives a brief survey of present development and describes the processes and more important plants.

ELEMENTARY DYNAMICS; a Text-Book for Engineers.

By J. W. Landon. Cambridge. University Press, 1920. 246 pp., diagrams, 7 x 5 in., cloth. $3.25. (Gift of The Macmillan Company.)

The author of this text-book believes that many of the beginner's difficulties in grasping the fundamental principles of dynamics arise from an over-emphasis of mathematics. This difficulty he attempts to avoid by emphasizing the physical ideas, whose meaning he explains partly by definition and description, but mainly by worked examples in which formulas are avoided as far as possible.

ELEMENTARY LESSONS IN THE MATHEMATICS OF ELECTRICITY.

By R. W. Kent. Minneapolis, the Dunwoody Institute, 1920. 72 pp., 9 x 6 in., paper. $1.00.

This pamphlet is intended to instruct journeymen and others in the electrical trade in the fundamentals of arithmetic and simple algebra. The ordinary methods of calculation are explained and problems are provided, illustrating their application to electrical calculations.

ELEMENTS OF MECHANISM.

By Peter Schwamb, Allyne L. Merrill, Walter H. James. Third edition. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Ltd., 1921. 372 pp., diagrams, 9 x 6 in., cloth. $3.50.

After sixteen years, this text-book appears in a thoroughly revised and expanded edition, embodying the changes suggested by its use for instruction at the Massachusetts Institute of Technology and other colleges. It is intended to provide a systematic, clear, practical presentation of the subject, suited to the amount of time usually devoted to it in college courses.

ERTRAGREICHSTER AUSBAU VON WASSERKRAFTEN.

Von Dr. Ing. Leiner. Munchen und Berlin, R. Oldenbourg, 1920. 111 pp., diagrams, 11 x 8 in., paper. 40M.

The author examines the principles which serve as a guide in estimating the probable financial returns from the utilization of a water-power; then he studies the most advantageous method of development, depending upon the constancy or intermittency of the power, the possibility of using reservoirs, and similar factors.

THE ESSENTIALS OF ADVERTISING.

By Frank Leroy Blanchard. First edition. N. Y. and Lond., McGraw-Hill Book Co., 1921. 322 pp., illus., 8 x 6 in., cloth. $3.00.

The purpose of the writer of this book is to outline and discuss, as briefly and as clearly as possible, the fundamental principles upon which advertising practise is based, the preparation of copy, the special advantages of the several mediums employed, the duties of advertising managers, agents and salesmen and such other information as will give the student a comprehensive view of the subject.

FIELD METHODS IN PETROLEUM GEOLOGY.

By G. H. Cox, C. L. Dake and G. A. Muilenberg. First edition. N. Y. and Lond., McGraw-Hill Book Co., Inc., 1921. 305 pp., map, illus., tables, 7 x 5 in., cloth. $4.00.

In a volume of pocket size the authors have provided a systematic discussion of the minutiae of field procedure in this specialized branch of engineering geology. The book describes the instruments and methods in general use, discusses the geologic criteria used in correlating beds and indentifying structures, and gives directions for organizing field parties, carrying on work in the field and preparing maps and reports. An appendix contains the necessary tables.

GAGE DESIGN AND GAGE-MAKING.

By Erik Oberg and Franklin D. Jones. First edition, first printing. N. Y., The Industrial Press; Lond., The Machinery Publishing Co., Ltd., 1920. 310 pp., illus., diagrams, 9 x 6 in., cloth. $3.00.

Much, the authors state, has been published on manufacturing practise, but comparatively little on the design and making of the gages used to control manufacturing processes and insure interchangeability in finished parts. Their book is intended to present the principles upon which gage design depends, and to describe the methods of manufacturing, measuring and testing gages.

HYDRO-ELECTRIC DEVELOPMENT.

By J. W. Meares. Lond. and N. Y., Sir Isaac Pitman & Sons Ltd., (Pitman's technical primer series). 90 pp., front., illus., 6 x 4 in., boards. $1.00.

This little primer, based on the author's experience, aims to set down in logical order, the points which require attention in the discovery, reconnaissance and final design of a hydroelectric scheme. It is confined strictly to the hydraulic aspect of the problem, omitting electrical questions and the practical details of plant construction.

DIE KOMPRESSIONS—KALTEMASCHINE.

By W. Koeniger. Munchen und Berlin, R. Oldenbourg, 1921. 204 pp., plates, tables, diagrams, 9 x 6 in., paper. 30M.

This book is based on an extensive investigation of sulfurous-acid refrigerating machines by its author. New views resulted which contributed to a solution of the question why the "wet" process of compression is less efficient than the "dry," and which also led to new methods for the calculation of refrigerating machines. The book is intended for students of the theory of these machines and for designers, and includes both sulfurous-acid and ammonia machines.

KUGELLAGER UND WALZENLAGER IN THEORIE UND PRAXIS.

Von Paul Haupt. Munchen unde Berlin, R. Oldenbourg, 1920. 199 pp., tables, diagrams, 9 x 6 in., paper, 18M.

This work is a summary and extension of the scattered literature on bearings with rolling friction. Besides a theoretical discussion of the laws underlying the construction of ball and roller bearings, current practise is described, and the commercial types are examined critically.

DAS KUGELPHOTOMETER (ULBRICHT'SCHE KUGEL).

Von Richard Ulbricht. Munchen und Berlin, R. Oldenbourg, 1920. 11 pp., 3 plates, diagrams, 10 x 7 in., paper. 24M.

This account of Ulbricht's spherical integrating photometer is based upon the papers which appeared in the *Elektrotechnische Zeitschrift* from 1900 to 1910. The investigations described therein are here presented in more systematic and connected fashion, with such revision and correction as has appeared necessary.

MECHANICAL WORLD YEAR BOOK, 1921.

Manchester and London, Emmott & Co., Ltd. 318 pp., illus., 6 x 4 in., cloth. 2s. 6d.

This inexpensive annual is intended as a convenient pocket reference book for mechanical engineers and shop superintendents. The most used data are given on steam engines and boilers, gas and oil engines, gas producers, the properties of metals, structural iron and steel work, toothed gearing bearings, belting, friction and lubrication, steam fitting, screws and similar subjects. A buyer's directory is included.

METHODS IN METALLURGICAL ANALYSIS.

By Charles H. White. Second Edition, revised. N. Y., D. Van Nostrand Co., 1920. 356 pp., illus., 7 x 5 in., cloth. $3.00.

This is a collection of the methods most frequently used in American metallurgical laboratories, arranged for use by students and works chemists. No previous experience in quantitative analysis is assumed, but sufficient detail is given to meet the needs of beginners.

MEXICO AND THE CARRIBEAN. Clark University Addresses.

Edited by George H. Blakeslee. N. Y., G. E. Steichert & Co. 1920. 363 pp., 9 x 6 in., cloth. $4.00. (Gift of Mr. Kirby Thomas.)

The Clark University Conferences upon International Relations are for the purpose of promoting a more intelligent understanding of our international problems, a more sympathetic appreciation of the attitude of other peoples, and a keener realization of our own international duties. This volume contains the addresses, delivered at the 1920 conference, upon Mexico and the Carribean, by business men, diplomats and others from the United States and the other countries concerned, which present the situation as seen by these experts and contain their recommendations for a national policy. Certain of them, notably Frederic R. Kellogg's upon the Mexican oil situation, and Kirby Thomas's upon business in the Carribean lands, are of special interest to engineers.

NEUE GRUNDLAGEN DER TECHNISCHEN HYDRODYNAMIK.

Von L. W. Weil. Munchen unde Berlin, R. Oldenbourg, 1920. 219 pp., illus., diagrams, 9 x 6 in., paper. 26M.

This work is concerned with some of the problems of hydrodynamics for which no exact elucidation or analytical solution has yet been obtained, as for example, eddies in streams and pipes, the effect of expansions or contractions in channels, orifice problems, water hammer and the theory of turbines and of rotary flow of liquids. The author advances certain principles, based on long theoretical and practical study, which he considers correct and in accordance with experimental results.

THE NEW THERMODYNAMICS; the non-postulated rationale of motive power of heat.

By Jacob T. Wainwright. Privately printed, 1921. 44 pp., 10 x 7 in., boards. (Gift of author.)

Believing that the second law of thermodynamics, which is the foundation for present day teaching of that branch of thermodynamics which treats of the motive power of heat, is untrue, the author presents his arguments for its repudiation. The monograph sets forth his views as to the rationale of the motive power of heat and his grounds for claiming that the Carnot principle conflicts with the principle of the conservation of energy and with observed results.

PATENT LAW.

By John Barker Waite. Princeton, University Press. Lond., Humphrey Milford, 1920. 316 pp., 9 x 6 in., cloth. $5.00.

In this volume the Professor of Law in the University of Michigan Law School presents a concise but complete and thorough discussion and exposition of the principles of patent law, intended for inventors, engineers and all that class of laymen who from time to time want information concerning their rights in respect to patents and inventions. It purports to cover only the substantive law of patents, their nature, validity, effect and their characteristics as property; and the author has attempted to present every issue that has come before the courts.

PERSONAL RECOLLECTIONS OF ANDREW CARNEGIE.

By Frederick Lynch. N. Y., etc., Fleming H. Revell Co., 184 pp., port., 8 x 6 in., cloth. $1.50.

Dr. Lynch's reminiscences cover a phase of Mr. Carnegie's activities that is not so widely known as his beneficences. His love of poetry and music, his religious opinions, interest in international peace, his views on education and similar topics, are set forth as he gave them to his friends.

PRACTICAL LOCOMOTIVE RUNNING AND MANAGEMENT.

By W. George Knight. Second edition, third thousand. Copyrighted 1920 by W. George Knight, Medford, Mass. 541 pp., illus., 8 x 5 in., cloth. $4.00.

This volume explains the construction and operation of the locomotive in detail, describes the accessories in detail and gives instruction in maintenance and methods of repair on the road. The book is intended for those who actually operate and maintain locomotives and is elementary in character.

PRIESTLEY IN AMERICA. 1794-1804.

By Edgar F. Smith, Phila., P. Blakiston's Son & Co., 173 pp., 7 x 5 in., cloth. $1.50.

From contemporary newspapers, documents and books, Dr. Smith has compiled the record of Priestley's life and literary and scientific activites, from his arrival in America until his death.

PRODUCER GAS.

By J. Emerson Dowson and A. T. Larter. Fourth edition. London and N. Y., Longmans Green and Co., 1920. 361 pp., illus., 9 x 6 in., cloth. $7.50.

Contents: Theory of producer gas.—Furnace work.—Heating work.—Engine work.—Suction plants.—Gas from bituminous coal for engine work.—Producer gas from peat.—Gas traction on roads.—Gas propulsion of vessels.—Stand-by losses.—Comparison of gas and steam power.—Fuel.—Analysis of fuel and of producer gas.—Calorific power of solid and gaseous fuels.—Practical notes. Appendixes.

The table of contents shows the scope of this treatise, which

gives a general survey of present practise in the production and utilization of producer gas. This edition has been thoroughly revised.

RED-LEAD AND HOW TO USE IT IN PAINT.

By Alvah Horton Sabin. Third edition, rewritten and enlarged. N. Y., John Wiley & Sons, Inc.; Lond., Chapman & Hall, Limited, 1920. 139 pp., illus., tables, 8 x 5 in., cloth. $2.00.

Like the preceding editions, this little book sets forth the essential facts concerning the manufacture of red lead, its preparation as a paint and the methods of using it based on thirty years' experience and study. The present edition is rewritten and considerably amplified.

STORAGE BATTERIES.

By C. J. Hawks. Minneapolis, The Wm. Hood Dunwoody Industrial Institute. 157 pp., illus., diagrams, charts, 9 x 6 in., cloth. $2.00.

This description of the theory, construction and operation of storage batteries in intended as an instruction book for the use in industrial schools and workmen's classes. The detailed construction of various types of cells is given, the methods of assembling, charging and testing are explained, with instruction in repair work.

TASCHENBUCH FUR SCHIFFSINGENIEURE UND SEEMASCHINISTEN.

By E. Ludwig and E. Linder. Dritte auflage. Munchen und Berlin, R. Oldenbourg, 1920. 12+502 pp., tables, diagrams, illus., 7 x 5 in., cloth. 24M.

This book is a third edition under a new title and with new compilers, of G. Bauer's "Kalender fuer seemaschinisten." In its present form it is a volume of convenient size, intended for marine engineers, and covering concisely all the mechanical equipment of ships. The volume contains the necessary physical and mathematical tables and formulas, sections on reciprocating steam engines, steam turbines, turbine reducing gear, boilers, boiler accessories, piping, combustion engines, auxiliary mechanical equipment, electrical equipment, measuring instruments, ship construction, navigation, laws and regulations. All these subjects are treated from a modern point of view, particular attention being given to methods likely to be used in the future.

TELEGRAPHY: A DETAILED EXPOSITION OF THE TELEGRAPH SYSTEM OF THE BRITISH POST OFFICE.

By T. E. Herbert. Third edition. Lond., and N. Y., Whittaker & Co., 1916. 20+985 pp., illus., 7 x 5 in., cloth. $6.50. (Gift of Isaac Pitman & Sons.)

This volume is a detailed description of the apparatus and methods used by the British Post Office, intended for students preparing for its examinations. Mathematical methods of exposition have been avoided. The present edition includes the many advances that have come since the issue of the preceding one in 1906, particularly in duplex, multiplex and automatic telegraphy.

A TEXTBOOK OF GEOLOGY.

By Amadeus W. Grabau. Part 1: General geology. N. Y. D. C. Heath & Co. 864 pp., illus., 9 x 6 in., cloth.

Dr. Grabau's treatise is intended as a standard text upon the subject, and while the needs of college classes have been kept in mind during its preparation, the author has also tried to produce a work of value as a work of reference. The volume differs from others of its kind in arrangement and also in the detailed attention given, wherever possible to typical examples of geological phenomena, rather than to generalizations with illustrations drawn from any sources.

TIME TELLING THROUGH THE AGES.

By Harry C. Brearley. N. Y., published by Doubleday, Page & Co., for Robert H. Ingersoll & Bro., 1919. 294 pp., plates, 9 x 6 in., boards. $3.00 (Gift of Robert H. Ingersoll & Bro.)

An interesting popular account of the subject from the earliest times to the present day, with special reference to the American watch industry. In addition to the main story, appendixes give a description of the mechanism of the watch, a bibliography, a chronological list of American watch manufacturers, a list of the chief collections of watches and an encyclopedic dictionary of terms.

A TREATISE ON CHEMISTRY.

By Sir H. E. Roscoe and C. Schorlemmer. Vol. 1. The Non-Metallic Elements. Fifth edition, revised by J. C. Cain. Lond., Macmillan and Co., Ltd., 1920. 968 pp., port., illus., 9 x 6 in., cloth. $9.00.

In this new edition the advances of chemistry during the past nine years have been incorporated so that the work is again up to date. The general style and character of the book has been preserved. It remains a fairly complete statement of the facts of modern chemistry and chemical theory, presented in readable form, with special attention given to the more important processes of technical chemistry and the most approved forms of apparatus employed in them.

TREATISE ON GENERAL AND INDUSTRIAL CHEMISTRY.

By Ettore Molinari, translated from the third Italian edition by T. H. Pope. Part 1. Phila., P. Blakiston's Sons & Co., 1921. 456 pp., illus., diagrams, 10 x 7 in., cloth. $8.00.

This book is characterized by an endeavor to combine, with the theoretical presentation of the subject, an extensive account of industrial processes and some information on the commercial aspects of production. It will be useful as a reference book.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Akron.—February 23, 1921. Paper: "Operating History of the Windsor Power Plant." Author: Mr. E. H. McFarland, Manager, Beech Bottom Power Plant. Attendance 47.

Baltimore.—February 25, 1921, Johns Hopkins University. Subject: "The Operating and Economical Advantages of Electric Locomotive." Speaker: Mr. A. H. Armstrong of the Railway and Traction Engineering Department of the General Electric Company. Attendance 120.

Chicago.—February 28, 1921, Western Society of Engineers. Subject: "Dependence of Aerial Transport upon Electricity." Speaker: Mr. Chas. F. Kettering, President, Dayton Engineering Laboratories Company. Attendance 250.

Cincinnati.—March 10, 1921, Assembly Hall, Union Gas & Elec. Co. Mr. W. S. Werner of the Kelley-Koett Mfg. Company, Covington, Ky., gave a very interesting talk on the history of the X-Ray and demonstrated the latest type of X-Ray apparatus. Attendance 60.

Cleveland.—February 15, 1921, Club Rooms of Cleveland Engineering Society. Subject: "Rates for Electrical Service as Viewed in the Light of the Present Economic Trend." Speaker: Mr. Paul M. Lincoln of the Lincoln Electric Company. Attendance 82.

Denver.—February 17, 1921, Albany Hotel. Mr. W. L. Winner, Instructor in Radio Educational Service, Fitzsimmons General Hospital, gave a very instructive talk on the radio telephone, illustrated by blackboard sketches. Mr. Winner gave a demonstration of the operation of a radio telephone which he had installed in the hotel. Music and conversations were transmitted from the hospital at Aurora to the hotel by wireless. The radio telephone in the hotel was equipped with a loud speaking receiving device which enabled everyone of the guests present in the room to hear the music and conversations distinctly. Attendance 200.

Fort Wayne.—February 11, 1921, Chamber of Commerce. Joint meeting with local Section of A. S. M. E. Mr. Calvin W. Rice, Secretary of the American Society of Mechanical Engineers, discussed the opportunities of the engineer in public service and pointed out just how the engineer, by proper organization, could assist the local community in the general solution of engineering problems. Attendance 75.

Indianapolis-Lafayette.—February 25, 1921, Chamber of Commerce Building, Indianapolis. Subjects: "Typical Utility

Service Complaints" by Mr. M. D. Atwater, Public Service Commission of Ind.; "Recent Development in Radio Telegraphy" by Mr. Francis Hamilton, American Radio Relay League. Attendance 75.

Kansas City.—February 25, 1921, University Club. Subject: "Human Engineering." Speaker: Chancellor Lindley of the University of Kansas. Attendance 64.

Los Angeles.—February 18 and 19, 1921, Polytechnic High School Auditorium. Joint meeting with the American Chemical Society and the Mathematics and Science Association. Subject: "The Structure of the Atom." Speaker: Dr. Robert A. Millikan. Attendance 765.

Lynn.—February 16, 1921. Subject: "Some Physical and Engineering Problems Connected with Guns and Projectiles." Speaker: Major Gordon F. Hull of Dartmouth College. The lecture covered the characteristics of air streams of high velocity: the factors determining forces on projectiles and other bodies; measurement of the retardation of a bullet; measurement of expansion of a gun during firing; and factors contributing to the bursting of guns. The talk was illustrated. Attendance 240.

Minnesota.—January 31, 1921, N. W. Telephone Building. Subject: "Problems of Unification of Manual and Automatic Telephone System in the Twin Cities." Mr. J. F. McDermott, Supervisor of the Development Division, discussed what the probable demands would be and the changes necessary to properly serve the public. Mr. C. B. Spring, General Equipment Engineer, from Omaha, explained the various methods of consolidating two systems of this kind, and explained why the present system was installed in the Twin Cities. He also explained fully, with the aid of slides, the operation of both the manual and the automatic systems. Dinner was served by the Northwestern Telephone Company in its cafeteria. Attendance 80.

New York.—February 25, 1921. On the evening of Feb. 25 in the Auditorium of Engineering Societies Building, New York, Dr. Saul Dushman, Research Engineer, General Electric Co. delivered a most interesting lecture on "Theory and Application of Hot Cathode Devices." The lecture was accompanied with interesting laboratory demonstrations of the action of the hot cathode under varying conditions and applications. Slides were shown illustrating various steps in the development of the kenotron and the pliotron. Dr. Dushman also touched on the development of the dynatron and the magnetron. Attendance about 900.

Directly preceding the lecture Chairman H. W. Buck called for a vote or amendment to the N. Y. Section By-laws permitting the earlier nomination and election of officers. Unanimous approval of the changes desired was obtained.

Philadelphia.—February 14, 1921, Engineers Club of Philadelphia. Informal dinner followed by addresses by Messrs. W. C. L. Eglin of the Philadelphia Electric Company; W. H. Hutt of the Federal Reserve Bank; H. B. Vincent of Day & Zimmerman; J. H. Tracy of the Electric Storage Battery Company. Attendance 102.

Pittsburgh.—March 8, 1921, Pittsburgh Chamber of Commerce Building. Two papers were presented as follows: "Electrical Features of Recent 100,000-H. P. Power Development at Niagara Falls" by Mr. J. Allen Johnson, Electrical Engineer of The Niagara Falls Power Company; "Salient Features of 32,500 Kv-a. Generator Design" by Mr. F. D. Newbury, Manager of Power Engineering Department, Westinghouse Elec. & Mfg. Co. Colored moving pictures by the Niagara Falls Power Company.

Pittsfield.—February 24, 1921. Subject: "Elements of the Automobile." Speaker: Dr. Rowland Rogers, Bray Studio, N. Y. Attendance 500.

March 3, 1921, Masonic Temple. Subject: "Instruments of the Orchestra." Speaker: Mr. John B. Taylor of the General Electric Company. Attendance 600.

Portland, Ore.—January 11, 1921, University Club. Subject: "The What and Why of Industrial Illumination." Speaker: Mr. O. L. Johnson. Refreshments were served after the meeting. Attendance 70.

Rochester.—February 25, 1921. Subject: "The Engineering Application of Electricity to the Automobile." Speaker: "Mr. G. R. Fessenden, Service Engineer of the Northeast Electric Company. Attendance 84.

San Francisco.—January 28, 1921, Engineers Club. Subject: "Pitt River Power Development of the Pacific Gas and Electric Company." Speaker: Mr. A. H. Markquart. Attendance 195.

Schenectady.—February 18, 1921, Edison Club Hall. Subject: "Making the Desert Bloom." Speaker: Mr. C. J. Blanchard, Statistician, U. S. Reclamation Service, Department of the Interior. Attendance 220.

March 4, 1921, Edison Club Hall. Subject: "The Economic Situation in Europe." Speaker: Mr. D. B. Rushmore of the General Electric Company. Attendance 220.

Seattle.—January 20, 1921, Bagley Hall, University of Washington. Joint meeting with the American Chemical Society and the Sigma Xi Fraternity. Subject: "The Chemistry of the Stars." Speaker: Dr. J. S. Plaskett, Director of the Canadian Government Astro-Physical Observatory at Victoria, B. C. Attendance 225.

February 14, 1921, Arctic Club Assembly. Subject: "Giving the Kilowatt a Show, Regardless of Whether the Kilowatt is used for Power Telephone or Radio Purposes." Speaker: Mr. R. W. Clark. Attendance 36.

Spokane.—January 7, 1921, Davenport Hotel. Illustrated lecture on "What and Why of Industrial Illumination." Attendance 67.

February 4, 1921, Davenport Hotel. A four reel motion picture on the subject "Coal is King" was shown and was followed by a discussion of the practises followed in the use of coal. Attendance 61.

Syracuse.—February 11, 1921, Technology Club. Subjects: "The Electric Furnace" by Mr. C. J. Rammling; "Brass Furnaces" by Mr. H. H. Plank. Attendance 62.

Toronto.—February 18, 1921. Joint meeting with Hamilton Branch of Engineering Institute of Canada. Subject: "Progress and Achievements in Radio Engineering." Speaker: Mr. Samuel M. Kintner. Attendance 180.

March 3, 1921. Joint meeting with the Toronto Branch of the Engineering Institute of Canada. Subject: "Ice Formation and Prevention." Speaker: Mr. John Murphy. Attendance 180.

Urbana.—February 25, 1921, Engg. Lecture Room, University of Illinois. Subject: "Rates and Rate Making." Speaker: Mr. Donald A. Henry. A film was also shown showing the process of manufacture of leather belting and another on the manufacture of storage batteries. Attendance 70.

Utah.—March 4, 1921, Commercial Club. Subject: "Electric Arc Welding." Speaker: Mr. E. Bachman of the General Electric Company. Attendance 65.

Vancouver.—February 4, 1921. Subject: "Electrification of Railroads." Speaker: Mr. F. W. McNeil. Attendance 24.

Washington, D. C.—March 8, 1921, Cosmos Club Hall. Subject: "Industrial Electrical Heating." Speaker: Mr. P. A. Meyer of the General Electric Company. Attendance 115.

Worcester.—February 25, 1921, Worcester Polytechnic Institute. Subject: "The St. Lawrence Project." Speaker: Mr. Henry I. Harriman, President, New England Power Company. Attendance 125.

PAST BRANCH MEETINGS

Alabama Polytechnic Institute.—February 3, 1921. Subject: "Hydroelectric Development." Speaker: Mr. J. D. Hurlbert. Attendance 26.

February 17, 1921. Subject: "The Methods of Hydro-

electric Development." Speaker: Mr. W. E. Mitchell of the Alabama Powers Company. Attendance 41.

University of Arkansas.—March 1, 1921. Subjects: "Conservation of Natural Resources" by Professor B. N. Wilson; "Electrical Apparatus Development During 1920" by Mr. H. B. Curtis; "Electrification of the Prussian Railways in Silesia" by Mr. Jack Thompson. Attendance 15.

Armour Institute of Technology.—February 18, 1921. Subjects: "Motion Picture Projectors" by Mr. Robert P. Burns; "Salesmanship" by Mr. Fletcher E. Hayden. Attendance 24.

Brooklyn Polytechnic Institute.—February 11, 1921. Subject: "Radio Engineering as a Profession." Speaker: Mr. Pierre H. Boucheron. Attendance 17.

February 24, 1921. Subject: "The Story of the Telephone." Speaker: Professor W. H. Freedman. Attendance 21.

University of California.—February 9, 1921. Subject: "Vacuum Tubes." Speaker: Mr. B. F. McNamee of the Moorhead Laboratories. Attendance 48.

February 23, 1921. Subject: "Illumination." Speaker: Mr. Prussia. Attendance 22.

California Institute of Technology.—February 24, 1921. Joint meeting with Chemistry Club and local Branch of A. S. M. E. Subject: "Electric Precipitation." Speaker: Mr. E. R. Wolcott of the Western Precipitation Company. Attendance 54.

Clemson Agricultural College.—February 18, 1921. Subject: "Mechanical Application of Electrical Motors." "Application in the Machine Shop" by W. W. Watkins; "Application to the Lumber Industry" by J. D. Salley; "Application to the Textile Industry" by W. M. Clatworthy; "Current Events" by F. D. Thomas. Attendance 25.

University of Colorado.—March 3, 1921. Subject: "Electrification of Steam Railroads." Speaker: Prof. M. S. Coover. Attendance 36.

Drexel Institute.—February 18, 1921. Business meeting followed by joint technical session with local Branch of A. S. C. E. Subjects: "Electrical Instruments" (lantern slides) by Wm. B. Creagmile (local Branch A. I. E. E.) "Clean Streets in Philadelphia" by James Follin (local Branch A. S. C. E.). Attendance 25.

Georgia School of Technology.—February 17, 1921. Subject: "Summer Work and Graduate Student Work." Speakers: Mr. L. E. Anderson, Westinghouse; Mr. H. E. Watkins, A. T. & T. Co.; Mr. C. C. Welchel, Westinghouse; Mr. J. O. Shepherd, G. E. Co. Attendance 27.

University of Iowa.—February 7, 1921. Election of officers as follows: Chairman, Charles Krause; Vice-Chairman, T. Varbedian; Secretary-Treasurer, A. P. Beyers. Attendance 34.

February 15, 1921. Subjects: "Course of Training in the U. S. Navy Steam Engineering School" by Mr. E. M. Apfel; "Cylinder Grinding" by Mr. I. MacDaniel; "Temperature Relays" by E. Paintin. Attendance 36.

Iowa State College.—February 16, 1921. Subjects: "Telephone Transmission" by Mr. G. H. Gray, Omaha Telephone Company; "Outside Plant Construction" by Mr. R. H. Fair, also of the Omaha Telephone Company. Attendance 35.

March 2, 1921. Subject: "Automatic Railway Substations." Speaker: Mr. John Drabelle, Iowa Railway and Light Company. Attendance 98.

University of Kansas.—February 9, 1921. Subject: "Problem of Finance." Speaker: Mr. J. T. Skinner, Manager of Kansas Electric Utilities Co. Attendance 18.

February 24, 1921. Subject: "The Utah Apex Mining Co., Bingham Cannon, Utah." Speaker: Mr. Harry Appleby '22. Refreshments were served. Attendance 91.

March 1, 1921. Subject: "Telephone Machine Switching." Speaker: Mr. W. E. Wickenden, Western Electric Company. Attendance 50.

Kansas State Agricultural College.—February 24, 1921. Election of officers as follows: Chairman, William Bucklee; Secretary, H. J. Staib; Treasurer, J. J. Seright. Subjects: "Home Lighting in the City of Manhattan" by Mr. W. C. Mars and "Electrification of Small Towns" by Professor C. E. Reed. Attendance 83.

March 3, 1921. Subjects: "Selling Your Services" by Mr. J. E. Byers; "The 'Three-Phase' Student" by Mr. Earl Thomas; "Illumination" by Mr. C. L. Zimmerman. Attendance 89.

University of Kentucky.—February 14, 1921. Subjects: "Regulation of Frequencies for Measurement Purposes" (A. I. E. E. February JOURNAL); "Progress of the Use of Electricity in the Industrial and Domestic Fields" (A. I. E. E. February JOURNAL); "Adjustable Laboratory Rheostats" (February *Electrical Engineer*). Attendance 22.

University of Maine.—February 16, 1921. Talks were given by Mr. W. S. Stevenson on summer work with the Westinghouse Company and Mr. J. Bernard on his work with the U. S. Air Mail Service. Attendance 26.

Massachusetts Institute of Technology.—February 17, 1921. Subject: "Labor in Production." Speaker: Mr. Mathew Poroshy of the Holtzer-Cabot Co. Refreshments were served. Attendance 54.

February 24, 1921. Subject: "Cable Construction." Speaker: Mr. E. W. Davis of the Simplex Wire and Cable Co. Refreshments were served. Attendance 65.

University of Michigan.—March 8, 1921. A talk was given by Mr. R. C. Bergrall, senior electrical engineer on power plants, relating especially to the problem of the electrification of a 450 mile stretch of road in Montana. Attendance 20.

School of Engineering of Milwaukee.—February 18, 1921. Subjects: "Engineering Reports from the Standpoint of the Practising Engineer" by Professor F. A. Kartak; "Relation of English to Engineering Reports" by Professor F. G. Fox; "Curves and Charts" by Professor Yeaton. Attendance 143.

University of Minnesota.—February 21, 1921. Subjects: "Radio-Telephony" by Mr. C. M. Jansky; "High-Frequency Phenomena" by Mr. E. C. Manderfeld and demonstration by Messrs. Manderfeld and Wessale. Attendance 85.

University of Missouri.—February 21, 1921. Subjects: "Inventory Methods for Valuation Purposes" by Mr. J. S. Palmer; "Valuation of Public Utilities" by Mr. O. J. Rotty; "Course of Training offered by the Century Electric Company" by Mr. O. S. Imes. Several reels of General Electric movies were also shown. Attendance 30.

March 8, 1921. Subject: "Transmission of Power at 220,000 Volts" by Mr. W. C. Austry. General Electric film "Queen of the Waves" was shown. Attendance 42.

Montana State College.—February 18, 1921. Moving picture film "King of the Rails" was shown. Attendance 359.

University of Notre Dame.—March 7, 1921. Subjects: "Report of the Berrien Springs Power Plant" by Mr. C. Tarnava, and "Report of the Elkhart Power Plant" by Mr. F. Miles. Attendance 18.

Oklahoma A. & M. College.—February 15, 1921. Subjects: "Automatic Stations" by Mr. M. C. Courtney and "A Summer's Work with the Oklahoma Railway Company" by Mr. Oral Baker. Attendance 19.

University of Pennsylvania.—February 11, 1921. Subject: "Electric Ship Propulsion" by Mr. K. McIlwain. Attendance 41.

February 18, 1921. Subject: "Electric Locomotives." Speaker: Mr. H. Peters. Attendance 41.

February 25, 1921. Subject: "Electric Starting Systems for Automobiles." Speaker: Mr. R. W. Robinson. Attendance 41.

University of Pittsburgh.—March 1, 1921. Subjects: "The Duquesne Light Company"—a description of its power plant at Bruno's Island, together with some features of its distribution system, by Mr. John J. Finnerty; "Commercial

Tests of Induction Motors at the W. E. & M. Co." by Mr. H. K. Aalborg. Attendance 21.

March 8, 1921. Subject: "The Vector Solution of an A-C. Single-Phase Distribution Line, Containing Uniformly Distributed Impedance and Leakage Resistance, but Having Zero Distributed Capacity"—a special case of the general distribution line problem applied to a-c. railroad signaling. Speaker: Mr. C. B. Bennett. Attendance 26.

Rensselaer Polytechnic Institute.—February 22, 1921. General Subject: "Recent Advances in Science and Engineering." Speakers: Mr. W. Byrne on "The Laws of Probability as Applied to the Choosing of the Number of Selectors for an Automatic Telephone Exchange"; Mr. H. Mimmo on "The Brown Tube"; Dr. Sebast contrasted the new Westinghouse oscillograph with the old type; Dr. Robb on "The Proposed Superpower Development;" Dr. Hunter on "The New Reported Method for Obtaining Aluminum from Ordinary Clay"; Professor Eldred on "The Proposed 220-Kilovolt Transmission Line in California"; Professor Williams on "The Recent Advances in the Telephone Game." Attendance 30.

Syracuse University.—February 18, 1921. Subject: "Stray Currents from Electric Railways." Speaker: Mr. Verdin. Attendance 13.

University of Texas.—February 14, 1921. Subjects: "Lightning Arresters" by Mr. Ray Barnard; "Railroad Block Signaling" by Mr. J. A. Jaccard; "Fuses" by Mr. B. A. Crocker; "Relays" by Mr. S. W. Marchall; "Protective Devices" by Mr. C. B. Lain. Attendance 25.

Virginia Military Institute.—February 12, 1921. Subjects: "Proposed Water-Power Development on the St. Lawrence" (material taken from article of similar nature in the *Electrical World* of February 8, 1921) Mr. Frederick P. Wilmer; "The Engineer and His Service" by F. F. Vaughan. Attendance 41.

February 24, 1921. Joint meeting of all departments of engineering. Address by Mr. Homer I. Ferguson, President of the Newport News Shipbuilding and Dry Dock Company. The talk was general in its nature but was of particular interest to those students about to enter the engineering field. Attendance 500.

University of Washington.—February 3, 1921. Subject "Making the Telephone Talk." Speaker: Mr. Scott, Chief Engineer of the City Telephone Company. Attendance 20.

State College of Washington.—February 25, 1921. Subject: "The Uses of the Vacuum Tube in Radio Work." Speaker: Dean H. V. Carpenter. Attendance 38.

West Virginia University.—February 21, 1921. Subjects: "The Engineering Profession Fifty Years Hence" by Mr. H. S. Shinn; "The Corona Voltmeter" by Mr. H. Chandler; "Welding Mild Steel" by Mr. R. L. Sheffer. Attendance 14.

Yale University.—March 8, 1921. Subject: "Water-Power Development." Speaker: Mr. Calvert Townley. Attendance 78.

March 11, 1921. Subject: "Industrial Illumination." Speaker: Mr. L. I. Edgerly. Attendance 60.

EMPLOYMENT SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after a period of three months, during which period names and records will remain in the active files.

NOTE.—Notices for the JOURNAL should be addressed to EMPLOYMENT SERVICE, 33 West 39th Street, New York, N. Y., the employment clearing house of the Societies constituting the Federated American Engineering Societies.

Notices for the JOURNAL are not acknowledged by personal letter, but they will usually appear in the next issue that goes to press.

All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to EMPLOYMENT SERVICE, as above.

Replies received by the bureau after the position to which they refer has been filled will not be forwarded, and will be held by the bureau for one month only.

Information regarding the notices published is on file in the offices of the member societies of the Federated American Engineering Societies.

OPPORTUNITIES

CHIEF DRAFTSMAN, experienced in air compressors. Must understand the theory of compressed air and be able to design. Steam pump experience will be considered. Location Illinois. X-90.

SALES ENGINEER with technical education or Extensive practical experience with Alternating current Motors by well established manufacturer located west of the Mississippi River. Correspondence confidential. Give full partiuclars. X-216.

INSTRUCTOR in Electrical Engineering. Knowledge of modern telephone practise and theory important but not essential. Location Ohio. X-237.

TELEPHONE ENGINEERS with sufficient telephone training to handle central office engineering work. X-239.

MANUFACTURER of Power and Heating Apparatus requires services of Mechanical Engineer to act as assistant director of experimental test and development. Ability to lay out and direct work of employees in this Department is of more importance than ability to carry out processes personally. Executive ability, a clear knowledge of mechanics and usual shop practises, experience in development work along similar lines and persistence for overcoming difficulties, are necessary qualifications for this position. First letter should state age, training, experience, present connection, salary desired and facts concerning personality and mechanical and executive ability. X-244.

ELECTRICAL ENGINEER to manage branch office located in central New York. Want a man familiar and experienced in business of an electrical contractor, and preference would be given to a man who has been engaged in this business himself. X-256.

ENGINEER to take charge of plant on brass sheets, rods and tubes. Must be good plant executive, who is familiar with management of such a plant, and must have sufficient technical knowledge of metallurgy to look after his own plant properly. X-259.

CAPABLE MASTER MECHANIC for plant consisting of 5 General Electric 500-kw. turbo-generators, with 500-kw. motor generator sets for railway and corresponding boiler plant and condensing equipment. Should like to get man that has had experience in such work, but principal quality is

to be first class machinist, who can show mechanics how to do accurate repair work and at the same time has experience enough to know when repairs, should be made to machinery in question, before it gets in bad condition. Also have in connection with plant small machine shop, a lathe, 2 drill presses, grindstones, pipe cutting machine, and emery wheel; but expect to increase machinery in near future by a shaper and another lathe, so we can do nearly any kind of repair work ourselves. Prefer man who can speak Spanish language. Location Mexico. X-264.

FIRM OF ELECTRICAL CONTRACTORS with record of 10 years of increasing and profitable business, because of increased burden on existing members, desires to secure young man with electrical training and some practical experience,as partner or associate, to become actively interested and grow with the business. Nominal investment to secure interest and permanency will be required. Good profit on investment plus adequate salary to right man. This is opportunity for some one to enter a successful business and have a real voice in its conduct. Main question is to secure man whose age, training, experience and personality fit in with present partners. Location New York City. X-266.

INSTRUCTORS, two, in Electrical Engineering Department. Location Southern America. X-267.

ASSISTANT PROFESSORS, two, in Electrical Engineering Department. Location Southern America. X-268.

ENGINEER experienced in microscopy, photography, physics, and chemistry for research work in laboratory of large rubber company. Location New York City. X-269.

ENGINEER to sell propellers and accessories to boat builders, manufacturers of marine engines, dealers and others, propellers and bronze castings for ships; also small electric generators. Prefer a man about thirty years old as he will be on the road a great deal of the time. Previous selling experience essential. Splendid opening with chance for advancement and a permanent position. X-290.

CAPABLE ENGINEER to take charge of Shanghai office. Desire partner who will invest ten or twenty thousand dollars fair basis, good salary and profits of business, totaling last year four hundred thousand dollars order from twenty sole agencies. China representatives finance any orders. X-142.

MEN AVAILABLE

MECHANICAL AND ELECTRICAL ENGINEER, graduate in 1910; broad experience in design and supervision of construction of power plant and industrial building, including electrical, mechanical, steel and concrete equipments Stone and Webster experience. Connection with consulting engineering concern is most desirable. Starting salary $4000 in New York. E-2585.

ELECTRICAL ENGINEER, age 36; ten years experience in power station design, construction operation and industrial engineering. Assoc. A. I. E. E. Extensive purchasing and executive experience. Desirous of entering engineering sales field or executive position. Salary $3500-5000. Available at once. E-2586.

TECHNICAL GRADUATE, 1918; single. Has had experience in test, design and commercial departments of large electrical manufacturer. Would like position with consulting engineering firm, construction concern, or power company. Would consider going to Philippine Islands. Available April 1st. E-2587.

PARTNERSHIP CONCERN having comprehensive knowledge of eastern territory and requiremens of the field and extensive clientele, desires exclusive representation for high grade article, preferably mechanical devices, such as commodity handling apparatus. Location New York City. E-2588.

ELECTRICAL ENGINEER, technical graduate, experienced in design, construction and maintenance, desires position as electrical engineer for industrial concern or supervising engineer on construction. Age 30; married. Salary expected $3600. Assoc. A. I. E. E. E-2589.

GRADUATE ELECTRICAL ENGINEER, age 27; married. Three years good practical experience, power house, sub-station and transmission line. Assistant construction engineer. Not afraid of hard work. Would like permanent position with bright future. Kind of work or location optional. E-2590.

ELECTRICAL ENGINEER, recent graduate of University of Michigan; age 25; single. Desires position affording opportunity for advancement. Would consider work in foreign fields, especially South American or Panama. Available immediately. E-2591.

ELECTRICAL ENGINEER. Eleven years experience in manufacture and sale of automobile electrical equipment, storage batteries, train lighting and welding machinery, desires position in charge of development or sale of electrical machinery or control devices. E-2592.

TESTING ENGINEER, B. S. degree, desires position with consulting engineer or manufacturing company in vicinity of Philadelphia. Five years experience in electrical, mechanical and materials testing. Assoc. A. I. E. E. Age 26. E-2593.

SALES ENGINEER desirous of operating several high grade nonconflicting accounts in central and western New York State territory. Several years successful commercial and professional engineering experience. E-2594.

ELECTRICAL SUPERINTENDENT, technical training, twelve years experience central stations, industrial plants, construction and maintenance, familiar with electrical contracting and its requirements, transmission systems up to 110,000 volts, electric precipitators, cranes, locomotives, turbines, chlorine cells, supplies, automatic control apparatus, electric welding, can design and lay out electrical equipment for industrial plants, can handle any number of men and work demanding executive and organizing ability, energetic tactful, age 32; married. Member of A. I. E. E.; A. I. and S. E., E-2595.

GRADUATE ENGINEER, 6½ years industrial plant maintenance and construction experience on design and field inspection of erection; buildings conveyers, heating and piping systems, property surveys, sewers and trackwork. Excellent references. E-2596.

SALES ENGINEER, desirous of taking on number of high grade non-interfering accounts for operation in vicinity of New York and for export to foreign countries. Fifteen years experience in sales engineering work. Successfully introduces a number of products and with existing organization in position to quickly penetrate trade with several new lines. E-2597.

GRADUATE ELECTRICAL ENGINEER; age 31; married. Ten years experience in design selection and ordering of materials, construction and operation of electrical power and industrial equipment of large installations. Seeks position offering great enough opportunities to warrant permanent residence. Available on short notice. Location preferred East Coast. Present salary $3000. Excellent references. E-2598.

PURCHASING AGENT, age 34. Five years experience in heavy electrical equipment supplies. Available immediately. E-2599.

GRADUATE ELECTRICAL ENGINEER, age 29. Two years General Electric test; one and one half years construction work; two years teaching in large university; one year in army. Would like to work for large public utility in a place where he can study operation and management of business. Western location perferred. E-2600.

GRADUATE ENGINEER, B. S. in M. E. 1919. Two years experience in d-c. and high voltage a-c. railroad electrification. Desire position with responsibility for advancement. Minimum salary considered $2000. Pacific coast preferred, but will go anywhere. E-2601.

ELECTRICAL MECHANICAL ENGINEER, age 24; desires position on construction or maintenance work as assistant chief or where opportunity for executive position is good. Foreign or domestic service. One year civil engineering; four years installation, manufacture and maintenance; one year safety engineer. Present time power plant engineer. Salary $2500. E-2602.

GRADUATE ELECTRICAL AND MECHANICAL ENGINEER. Five years experience in power plant layouts, installation, operation and maintenance mechanical and electrical apparatus. Age 27; married. Present salary $4000. Familiar with contracts and estimating. Desires position with consulting engineer; any other good offer considered. Location Louisiana, Tennessee, Oklahoma, Texas, Missouri, etc. E-2603.

EXECUTIVE. Engineering and business experience; Univeristy graduate; engineering and law; age 34. E-2604.

TECHNICAL GRADUATE with factory, construction, operating and commercial experience and training available on not less than two months notice as general superintendent or assistant to general manager of power company. Health unusually good, possesses strong reserve of physical and nervous energy. Good general business knowledge. E-2605.

INSPECTING SPECIALIST for railway cars and their equipment. Thoroughly acquainted with modern G. E. and Westinghouse apparatus for the single car, locomotive or multiple unit train of d-c. or a-c. types. Understands in detail central station apparatus from the condenser intake to transmission lines and its substations. E-2606.

ELECTRICAL ENGINEER, technical graduate, age 35; single. Two years experience small power plants and line work; ten years broad experience marine work, drafting, wiring, supervision installation apparatus, desires position offering broad opportunity for advancement in the vicinity New York or Philadelphia. Available short notice. E-2607.

ELECTRICAL AND MECHANICAL ENGINEER, thoroughly experienced, wants responsible position in New York. Executive, manager, superintendent, expert. Practised in manufacturing, development, maintenance and consulting. Large and small machines and appliances. Modern system. Directing large numbers male and female employees. B. S. and E. E. Univeristy of Pa. E-2608.

MECHANICAL AND ELECTRICAL ENGINEER. Technical training; age 38; married; with sixteen years experience in design, construction and operation of power, substation and distribution all tensions. Actually chief engineer large South American street railway light power concern. Thorough knowledge French, Portugese. Desires a change. South America or Southern Europe. E-2609.

ELECTRICAL-MECHANICAL ENGINEER age 42; married; university graduate. Fifteen years experience in this country and abroad in design, and construction of power and substations, electrical machinery and equipment and industrial engineering. Thoroughly conversant with a-c. and d-c. systems of distribution; high and low tension. E-2610.

GRADUATE ELECTRICAL ENGINEER. Twelve years experience designing, constructing, operating and appraising electrical properties, industrial plants, public utilities, etc. Position desired with progressive firm in North Central States. Available on short notice. E-2611.

ELECTRICAL ENGINEER, Member A. I. E. E. and A. S. M. E. age 41. Fifteen years experience in general industrial and, power plant engineering. Position preferred in Boston or New York City. Available in 30 days. E-2612.

FOREIGN REPRESENTATIVE, graduate electrical engineer, age 35; native of a Balkan State; working knowledge of French, Russian and most Slavic languages; four years experience with large western public service corporation; past three years in U. S. Government service. Further information gladly furnished. E-2613.

ELECTRICAL ENGINEER, graduate; age 33; married. Just completed installation of electrical equipment in one of the most up-to-date steel mills in the country. Can handle this sort of work for mills or factories in the most economical and efficient manner. Expert on reducing power bills. E-2614.

ELECTRICAL ENGINEER, technical graduate; age 27. Experienced in design of generating and substations, distribution systems, etc. Familiar with textile industry and modern production methods. G. E. test, training for sales engineer. Desires position in or near New England. E-2615.

EXPERIENCED SALES ENGINEER would consider change to position where compensation is commensurate with results and opportunity for growth exists. Familiar with central station, railway and mining equipment. E-2616.

GRADUATE ELECTRICAL ENGINEER, age 29; married. At present in transportation department of large street railway company, wishes to make change. Five years experience electric street railway maintenance and operation; nine months sales engineering experience with well known company, manufacturing electric wires and cables. Desires permanent position in sales engineering with company manufacturing electric railway supplies or other electrical machinery or devices. Would also consider permanent position in traffic analysis work or similar work allied to electric railway industry. New York City or middle Atlantic states preferred. References furnished upon application. Available on two weeks notice. Minimum salary $3000. E-2617.

GRADUATE ENGINEER, four years electrical experience in testing, laboratory, electrical construction of power houses, substation and transmission lines. Interested in generation and distribution of electric power. Familiar with design work and engineering economic studies. Age 29; single; American; protestant. Salary $2800. E-2618.

ELECTRICAL ENGINEER, age 25. Will graduate from college in June. Have also completed in I. C. S. course. Have been as assistant instructor while in college. Have had experience in construction work. E-2619.

INDUSTRIAL PLANT ELECTRICAL ENGINEER graduate; age 30; speaks Spanish. Nine years experience in design, selection and ordering of materials, construction and operation of electrical power and industrial equipment of large installations. Prefer proposition based on results attained. Seeks position offering great enough opportunities to warrant permanent residence. E-2620.

PRODUCTION OR SALES ENGINEER, age 27; married. Mechanical Electrical graduate with good commercial training. Three years experience production and engineering sales. Work covered; engineering correspondence, specifications; office methods; routing and scheduling machine work, drop hammers, crank and toggle presses, cost determination. Desire position in production or engineering sales. References furnished. E-2621.

ENGINEER EXECUTIVE, age 42. Twenty years experience in engineering, construction and maintenance of large public utility. College graduate. Desires connection with industrial or financial concern offering good opportunities. Large experience in organization, production, appraisal, accounting and labor problems. Present salary $6000. E-2622.

ELECTRIC DISTRIBUTION ENGINEER, age 29; technical graduate. Five years experience as superintendent of electric distribution department of large public utility serving a population of approximately 100,000. Location desired New York State or vicinity. Best of references. Available on short notice. E-2623.

TECHNICAL GRADUATE, age 26; married. Five years experience drafting, marine work, wiring, electric meters, machine shop, electrical testing, Assoc. A. I. E. E. Desires position with chance for advancement. Available immediately. E-2624.

ELECTRICAL ENGINEER, technical graduate. Eight years experience covering hydroelectric and steam power plant and substation operation, maintenance, design and construction; extensive testing and repairing all electrical apparatus used; acceptance tests on new stations; overhead and underground distribution and street lighting systems. Ex-Captain U. S. Army. Desires position of responsibility with good future with central station organization or firm of consulting engineers. Pacific coast preferred. Best references; available short notice. E-2625.

ELECTRICAL ENGINEER, college graduate 1917; has had experience in telephone work, both automatic and manual; general plant maintenance; design and layout of power houses and sub-stations; and in general electrical research work. Desires something permanent in any locality. E-2626.

ELECTRICAL MECHANICAL ENGINEER, age 27; technical graduate. Four years experience in large and small factories. Good executive. Desires position with a growing concern. Would consider engineering sales proposition. Location immaterial. E-2627.

MECHANICAL ELECTRICAL ENGINEER seeking new connection, would like to hear from responsible parties. Expert on operation of industrial plants; capable executive; valuable purchasing experience. Technical education; sixteen years practical experience. Age 40; married; good health. E-2628.

ADDRESSES WANTED

A list of members whose mail has been returned by the Postal Authorities is given below, together with the addresses as they now appear on the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Leo Arany, Room 201 Parkway Bldg., Broad & Cherry Streets, Philadelphia, Pa.

2.—De Los De Tar, 411 East 15th Street. Kansas City, Mo.

3 —H. S. Logan, 215 15th Street, Seattle, Wash.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED MARCH 11, 1921

ALBRIGHT, JOHN J., Jr., Electrical Engineer, Niagara, Lockport & Ontario Power Co., Syracuse, N. Y.

ALLEN, ASA EDWARD, Engineer, Southwest General Electric Co., Interurban Bldg., Dallas, Texas.

ANDREWS, RALPH J., Sales Engineer, Sangamo Electric Co., Jackson, Mich.

ASCHENBRENER, RUDOLPH A., Power Salesman, The Milwaukee Electric Railway & Light Co., Public Service Bldg., Milwaukee, Wis.

*ASHENDEN, HARRY B., Student Engineer, Cutler-Hammer Mfg. Co.; res., Y. M. C. A., Milwaukee, Wis.

ASPINWALL, GEORGE L., Vice President, Atlantic Radio Co., 88 Broad St., Boston, Mass.

BAILEY, GEORGE L., Electrician, *New York World* 63 Park Row, New York, N. Y.

BAKER, CHARLES F., Electrician, West Penn Power Co.; res., 104 Lookout Ave., Charleroi, Pa.

BALDWIN, BENJAMIN W., Salesman, St. Paul Electric Co.; res., 2258 Commonwealth Ave., St. Paul, Minn.

BALLANTYNE, WILLIAM M. H., Chief Electrician, Penn Water & Power Co., Holtwood, Pa.

*BANY, HERMAN, Asst. Head, No. 16 Test, Testing Dept., General Electric Co.; res., 111 Nott Terrace, Schenectady, N. Y.

BARNES, CHARLES T., Asst. Sales Manager, Toronto & Niagara Power Co.; res., 241 Woodbine Ave., Toronto, Ont.

BASTIAN, HARRY S., Asst. Engineer, Portland Railway Light & Power Co., 507 Electric Bldg., Portland, Ore.

BEARSE, EDWIN W., Electrical Engineer, General Electric Co., 3rd National Bank Bldg., Atlanta, Ga.

BEAVERS, FRANKLIN J., Engineer, Electrical Dept., Gary Heat, Light & Water Co.; res., 801 Jefferson St., Gary, Ind.

BELL, FREDERICK N., Engineer, Control Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1001 Franklin Ave., Wilkinsburg, Pa.

BENN, SYLVESTER M., Testing Dept., General Electric Co.; res., Edison Club, Schenectady, N. Y.

BISWANGER, CHARLES W., Electrical Engineering Dept., Weston Electrical Instrument Co.; res., 639 So. Belmont Ave., Newark, N. J.

*BLASSINGHAM, LLOYD F., Tester, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 500 Todd St., Wilkinsburg, Pa.

*BLOOMBERG, SHELDON, Motor Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; Westinghouse Club, Wilkinsburg, Pa.

BOLSTER, FRANK T. Asst. Distribution Engineer & General Line Foreman, Syracuse Lighting Co.; res., 124 Miles Ave., Syracuse, N. Y.

SPRING, JOHN H., Test Dept., Canadian Crocker-Wheeler Co.; res., 122 Albert St., St. Catharines, Ont., Canada.

STACKHOUSE, CLIFTON C., Office Engineer, The Panama Canal, 1709 G St., N. W., Washington, D. C.

*STANTON, GEORGE T., Asst. Engineer, Signals & Telegraphs, T. & O. C. R. R., 370 W. Broad St., Columbus, Ohio.

STAYNER, J. HYDE, Meterman, Utah Power & Light Co.; res., 824 East 17th South, Salt Lake City, Utah.

STERBA, ERNEST J., Research Engineer, Western Electric Co., 463 West St., New York, N. Y.

STEVENS, DON L., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

STEVENS, WALTER F., Supt., Supply Dept., The Edison Electric Illuminating Company of Boston, 1165 Mass. Ave., Roxbury, Mass.

*STORZ, JACOB F., Junior Engineer, Henry L. Doherty & Co., 60 Wall St., New York, N. Y.; res., Ethel, La.

TADA, TORAO, Electrical Section, Engineering Dept., Mitsui & Co., 65 Broadway, New York, N. Y.

TALBOT, THOMAS F., Student Engineer, Testing Dept., General Electric Co.; res., 23 Mynderse St., Schenectady, N. Y.

TALBOTT, ARNOLD M., Engineer, Henry L. Doherty & Co., 60 Wall St., New York, N. Y.

TARBOUX, JOSEPH G., Instructor, Electrical Engineering, Cornell University, Franklin Hall, Ithaca, N. Y.

TAVENNER, FRANK L., General Foreman of Electrification, Chicago, Milwaukee & St. Paul R. R., Deer Lodge, Mont.

*TAYLOR, EDWARD W., Construction Dept., General Electric Co., Newark; res., 140 Prospect St., E. Orange, N. J.

*TESCH, WALTER C., Student, School of Engineering of Milwaukee; res., 270 Martin St., Milwaukee, Wis.

THOMPSON, JOHN H., Chief Engineer, Canadian Government Radio Service, Dept. of Naval Service, Ottawa, Ont.

*THROOP, ALBERT R., Telephone Engineer, Chicago Telephone Co.; res., 507 W. 65th St., Chicago, Ill.

THURBER, JAMES P., Asst. Engineer, New England Tel. & Tel. Co., 50 Oliver St., Boston, Mass.

*TINKER, EDWARD L., Student, Lehigh University, Bethlehem, Pa.; res., 480 Washington Ave., West Haven, Conn.

TITTLE, HARRY W., General Foreman, Electrical Dept., B. F. Goodrich Rubber Co.; res., 79 Bachtel Ave., Akron, Ohio.

TITUS, CONRAD, Station Supt., Vermont & Quebec Power Co., Richford, Vermont.

TORGESEN, TORRIS K., Electrical Engineer, 5732 Grand Central Terminal, New York, N. Y.

TRACY, J. LEE, Asst. Engineer, Traffic Dept., Western Union Telegraph Co.; res., 112 W. 12th St., New York, N. Y.

TRIVETT, MARTIN A., Electrical Tester, Interborough Rapid Transit Co., 600 W. 59th St., New York, N. Y.

*TRULL, FREDERICK G., Power Salesman, Toronto Hydro-Electric System; res., 177 Davenport Road, Toronto, Ont., Canada.

TURNER, ROBERT B., Power Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

TURNER, THEODORE, J., Electrical Foreman' Crescent Tool Co.; res., 20 Sherman St., Jamestown, N. Y.

TURNER, WILLIAM M., Foreman, Electrical Construction, The Atlantic Refining Co., Philadelphia, Pa.; res., 521 Harrison Ave., West Collingswood, N. J.

VARMA, GANESH LALL, Engineer, The Lakshmi Industrial Works, Ajmer-Rajputana, India.

*VERNON, FORD H., Sales Agent, General Electric Co., Rialto Bldg., San Francisco, Cal.

*WAGNER, HENRY O., Sales Agent, General Electric Co., 1501 Dime Bank Bldg., Detroit, Mich.

WAINTRAUB, ALEXANDER, Electrical Draftsman, New York Edison Co., New York, N. Y.

WAINWRIGHT, STUART F., Electrical Draftsman, So. California Edison Co., Edison Bldg.; res., 1926 Delta St., Los Angeles, Cal.

WALZ, JAMES O., Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 517 Elliott St., Wilkinsburg, Pa.

WARDLE, BERTRAM, Draughtsman, Canadian Crocker-Wheeler Co., St. Catharines, Ont., Canada.

WATERS, WILLIAM, General Foreman, Overhead Dept., Toronto & Niagara Power Co., & Toronto Railway Co.; res., 204 Beatrice St., Toronto, Ont.

WEBER, JOHN C., Electrical Inspector, Engg. Dept., Northern Indiana Gas & Electric Co., Hammond, Ind.

WESTIN, CARL L., Engineer, Motor Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 114 6th St., Turtle Creek, Pa.

WHITBECK, HOWARD S., Asst. Supt. of Construction, Pacific Power & Light Co., Kennewick, Wash.

WHYTE, JAMES S., Works Engineer, Canada Carbide Co. Ltd.; res., Cascade Inn, Shawinigan Falls, P. Q.

WIGGLESWORTH, FRANK, President & Treasurer, Atlantic Radio Co., 88 Broad St., Boston, 9, Mass.

*WILDES, KARL L., Instructor in Mathematics, Mass. Institute of Technology, Cambridge 39, Mass.

WILLEN, NILS G., Order Clerk, The Cutler-Hammer Mfg. Co., 50 Church St., New York, N. Y.

WILLIAMS, ALEXANDER T. Laboratory Engineer, Crocker-Wheeler Co., Ampere; res., 437 Badger Ave., Newark, N. J.

WILLIAMS, H. H., Design Engineer, Control Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

WILLIAMS, JAMES P., Engineer, Transmission Dept., The Pacific Tel. & Tel. Co.; res., 124 E. 17th St., Portland, Ore.

WOOD, JOYCE L., Draftsman & Switchboard Engineer, The Pacific Tel. & Tel. Co., 503 Telephone Bldg., Portland, Ore.

WYCKOFF, JOHN S., JR., Electrical Engineer, Motor Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 311 Pitt St., Wilkinsburg, Pa.

Total 321.

*Former enrolled students.

ASSOCIATES REELECTED MARCH 11, 1921

GILLILAND, CLARENCE R., Manager, Railway & Power Depts., Westinghouse Elec. & Mfg. Co., 1104 Traction Bldg., Cincinnati, Ohio.

KOBAK, EDGAR, St. Louis Representative, McGraw-Hill Co., Inc., 713 Star Bldg., St. Louis, Mo.

MILLER, PETER C., Chief Engineer, Electrical & Mechanical Dept., C. H. Mead Co., Buckley, W. Va.

POLLOCK, ROBERT T., President & Treasurer, Robert T. Pollock Co., 38 Fairfield St., Boston, Mass.

PORTA, PETER, Foreign Dept., Shipley Construction & Supply Co., 42nd & 2nd Ave., Brooklyn, N. Y.

RUTZ, E. C., President, R. & W. Construction Co., 35 S. Desplaines St., Chicago, Ill.

SPEER, GUY F., Public Service Bldg., Milwaukee, Wis.

TOEPPEN, MANFRED J., Appraisal Engineer, Michigan Public Utilities Commission; res., 8837 Clarendon Ave., Detroit, Mich.

WILKINSON, THOMAS W., Equipment Engineer, Kansas City Telephone Co.; res., 3423 "A" Forest Ave., Kansas City, Mo.

ASSOCIATES REINSTATED MARCH 11, 1921

FLOOD, HENRY, JR., Engineer-Secretary, Superpower Survey, 709 Sixth Ave., New York, N. Y.

GERHARDT, CARL L., Electrical Engineer & Draftsman, United Verde Copper Co., Clarkdale, Ariz.

MORGANS, FRANK D., Engineer, Holton Power Co., 120 S. 6th St., El Centro, Cal.

MEMBERS ELECTED MARCH 11, 1921

BIRCKHEAD, LENNOX, Asst. Electrical Engineer, Consolidated Gas, Electric Light & Power Co., Baltimore; res., Towson, Md.

BODGE, HAROLD H., Electrical Engineer, General Electric Co., 84 State St., Boston, Mass.

BURRILL, H. G., Asst. to Supt. of Steam Stations, Consolidated Gas, Electric Light & Power Co.; res., 3609 Windsor Mills Road, Baltimore, Md.

DOWS, CHESTER L., Electrical Engineer, National Lamp Works, Nela Park, Cleveland, Ohio.

ELLIOTT, ROY K., Electrical Engineer, General Electric Co., Boston; res., 20 Bay State Ave., Somerville, Mass.

EVANS, G. L., Asst. Vice-President, Wagner Electric Mfg. Co., 6400 Plymouth Bldg., St. Louis, Mo.

FERNHOLZ, WILLIAM H., District Manager, Electrical Engineer's Equipment Co., 453 E. Water St., Milwaukee, Wis.

FISH, JOSEPH P., Electrical Engineer, Stone & Webster, 147 Milk St., Boston, Mass.

GRIFFIN, G. BREWER, Manager, Automotive Equipment Dept., Westinghouse Elec. & Mfg. Co., 82 Worthington St., Springfield, Mass.

HENRY, DONALD A., Engineering Dept., Public Service Utilities Commission, Springfield, Ill.

HJORT, ALF, Electrical & Mechanical Engineer, Booth & Flynn, Ltd.; res., 251 Fort Washington Ave., New York, N. Y.

HOLBROOK, AUGUSTUS T., General Sales Manager, Multiple Electric Products Co., Inc., 450 4th Ave., New York, N. Y.

HOWARD, JOHN J., Electrical Engineer, The Connecticut Co., 129 Church St., New Haven, Conn.

INGLIS, WILLIAM, Electrical Engineer, Messrs. Matthews & Yates Ltd., Cyclone Works, Swinton, near Manchester, Eng.

KIRKPATRICK, F. O., Manager, Industrial Div., Westinghouse Elec. & Mfg. Co., 1107 Traction Bldg., Cincinnati, Ohio.

KOCH, MAX, Directeur, de Service Commercial a la Francaise Thomson-Houston Co., 4 Rue d'Aguesseau, Paris, France.

KONDO, SHIGERU, Director & Chief Engineer, Nihon Hydraulic Power Co.; res., 29 Ovancho, Yotsuya-Ku, Tokyo, Japan.

MARROTTE, LOUIS H., Asst. to Chief Engineer, Montreal Public Service Corp., Montreal, Quebec, Can.

McLANAHAN, ALLEN, Electrical Engineer, Central Limones, Limonar, Cuba.

MUSTARD, JOHN H., Professor of Electrical Engineering, University of North Carolina, Chapel Hill, N. C.

WARE, JOHN S., Distribution Engineer, Public Service Electric Co., 80 Park Place, Newark, N. J.

TRANSFERRED TO GRADE OF FELLOW MARCH 11, 1921

RIDDILE, J. S., Manager of Power, Laurentide Power Co., Ltd., Grand Mere, Quebec.

TRANSFERRED TO GRADE OF MEMBER MARCH 11, 1921

ANDERSON, OSCAR V., Superintendent, Distribution Dept., Toronto & Niagara Power Co. and Toronto Railway Co., Toronto, Ontario.

BAKER, CAREY W., Engineer, Transformer Dept., Canadian Westinghouse Co., Hamilton, Ont.

BEAUBIEN, JAMES DE GASPE, Consulting Engineer, Montreal, Quebec.

COLE, HORACE L., Engineer, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

CORIELL, LOUIS D., Periodontist and Radiologist, Baltimore, Md.

HAISLIP, RICHARD A., Telephone Engineer, Dept. of Development & Research, American Telephone & Telegraph Co., New York, N. Y.

HEWSON, WILLIAM G., Railway Engineer, Hydro-Electric Power Commission, Toronto, Ont.

HOLMES, HOWARD A., Engineer, Morris Knowles, Inc., Pittsburgh, Pa.

KENT, JAMES MARTIN, Teacher and Consulting Engineer, Manual Training High School, Kansas City, Mo.

SEABURY, RICHARD W., President, Boonton Rubber Mfg. Co., Boonton, N. J.

WALTER, HENRY C., Electrical Engineer, Allis-Chalmers Mfg. Co., Milwaukee, Wis.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its meetings held February 11 and March 4, 1921, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

YOKURA, MORINOSUKE, Engineer-Captain Chief of Electrical Engineering Bureau, Imperial Japanese Navy, Tokyo, Japan.

To Grade of Member

AMOS, WALTER L., Electrical Engineer, Engineering Dept., Hydro-Electric Power Commission of Ontario, Toronto, Ont.

BEACH, ROBIN, Acting Head of Electrical Engineering Dept., Polytechnic Institute, Brooklyn, N. Y.

BOND, JOHN MILTON, Head of Car Equipment Test Dept., Interborough Rapid Transit Co., New York.

CORNELL, ROBERT L., Vice-President, Industrial Supply & Engineering Co., Lexington, Ky.

CRICHTON, LESLIE N., Section Engineer, Supply Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

DELLENBAUGH, FREDERICK S., JR., Secretary, Research Division, Electrical Engineering Dept., Massachusetts Institute of Technology, Cambridge, Mass.

FAY, FRANK H., Supervisor, Printing Telegraph Service, American Telephone & Telegraph Co., New York.

FLOOD, HENRY, JR., Engineer-Secretary, Superpower Survey, U. S. Geological Survey, New York.

FURUICHI, TATSUWO, Engineer Lieutenant-Commander, Imperial Japanese Navy, Tokyo, Japan.

GAYLORD, TRUMAN P., Acting Vice-President Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

GILLILAND, CLARENCE R., Manager, Railway & Power Depts., Westinghouse Elec. & Mfg. Co., Cincinnati, Ohio.

HERR, EDWIN M., President, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

HOFFMAN, A. J., Electrical Engineer, Lockwood, Greene & Co., Chicago, Ill.

RYLANDER, JOHN L., Electrical Engineer, Motor Engineering Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

SHREEVE, HERBERT E., Telephone Engineer, Western Electric Co., New York.

SPENCER, BURT K., Assistant Engineer with A. G. Wood, Philadelphia, Pa.

THURSTON, ERNEST B., Electrical Engineer, Haughton Elevator & Machine Co., Toledo, O.

TOEPPEN, MANFRED K., Appraisal Engineer, Michigan Public Utilities Commission, Detroit, Mich.

TRIPLETT, HUGH A., Electrical Construction Engineer, Midland, Pa.

WOOD, HENRY BLAKE, Electrical Engineer, Stone & Webster Inc., Boston, Mass.

APPLICATIONS FOR ELECTION

Abbott, Gordon A., Toronto, Ont.
Alexander, H. Gordon, Manitoba, Canada
Anderson, Herbert M., Erie, Pa.
Angove, Raymond H., Milwaukee, Wis.
Armstrong, Robert B., Wenatchee, Wash.
Armstrong, Walter R., Salt Lake City, Utah
Atkinson, William H., Washinton, D. C.
Barton, Harold F., (Member), Syracuse, N. Y.
Beck, Robert C., New York, N. Y.
Begley, Francis P., Coshocton, Ohio
Berry, Oliver F., E. Pittsburgh, Pa.
Black, John, Niagara Falls, Canada
Blackwedel, George H., New York, N. Y.
Blersch, Roy E., Cleveland, Ohio
Bliss, Mervin W., Amherst, Mass.
Blosser, Herman G., Swissvale, Pa.
Borgardt, John B., Cleveland, Ohio
Bowen, Hiram, Seattle, Wash.
Boyce, Harry, New York, N. Y.
Brady, Terence M., Effingham, Ill.
Braun, Carl H., Cleveland, Ohio
Breslin, Edward T., Worcester, Mass.
Brown, G. Jay, Cassel, Cal.
Burns, Robert P., Chicago, Ill.
Cahoon, Chester P., (Member), Murray, Utah
Callender, Delmer W., Hamilton, Canada
Cannell, J., Hartford, Conn.
Cardoso, Antonio C., E. Pittsburgh, Pa.
Carlsen, Nels P., San Francisco, Cal.
Carroll, John D., New York, N. Y.
Carstein, L. W. F., Long Beach, L. I., N. Y.
Cates, Richard H., Los Angeles, Cal.
Chaichin, Abraham, New York, N. Y.
Chapman, William V., Portland, Ore.
Charley, Reginald M., Pittsburgh, Pa.
Chow, Kon-Puh, Philadelphia, Pa.
Christen, Arthur E., St. Johns, Newfoundland
Church, Arthur D., Santa Maria, Cal.
Clark, Harold M., (Member), Toronto, Ont.
Coffman, Raymond N., Newark, Ohio
Coghlin, Charles C., Worcester, Mass.
Coler, Carl S., E. Pittsburgh, Pa.
Convery, John H., Peterboro, Ont.
Coolidge, William H., Jr., Magnolia, Mass.
Cordes, Henry R., Jr., New York, N. Y.
Corten, Theodore, Jr., Chicago, Ill.
Coxhead, Harry B., New York, N. Y.
Cronan, Philip G., Washington, D. C.
Curtis, Frederick, Detroit, Mich.
Curtis, Harvey L., Washington, D. C.
Daly, Charles J., New Haven, Conn.
Day, Irvin W., (Member), Waterbury, Conn.
De Merit, Merrill W., Detroit, Mich.
DeViney, Albert F., Chicago, Ill.
Doughman, Ferman C., E. Pittsburgh, Pa.
Dring, George S., New York, N. Y.
Dunning, Samuel G., Cleveland, Ohio
Earnshaw, John, Warren, R. I.
Edom, William E., Detroit, Mich.
Elliott, John T., Erie, Pa.
Enriques, Alfonso, Manila, P. I.
Ewart, James B., New York, N. Y.
Ferguson, John S., Bend, Ind.
Fessenden, George R., Rochester, N. Y.
Fick, Ernest, Chicago, Ill.
Fitz, J. Allen, Brooklyn, N. Y.
Fitzpatrick, Robert W., Atlanta, Ga.
Fortier, Charles L., (Member), Milwaukee, Wis.
Francis, Francis, Toronto, Ont.
Freiburghouse, Edward H., Schenectady, N. Y.
Fuller, Howard H., Madison, Wis.
Geyer, Arthur N., (Member), Salt Lake City, Utah
Goldfarb, George, New York, N. Y.
Goodall, Arthur S., Lynn, Mass.
Graham, Frank H., New York, N. Y.
Grimshawe, Joseph L., Charleston, S. C.
Hagelin, Boris C. W., (Member), Elizabeth, N. J.
Hale, Frederick B., Long Island City, N. Y.
Hannibal, E. R., Spokane, Wash.
Harvey, Walter, Newark, N. J.
Hasemeier, Stanley H., Chicago, Ill.
Heitner, Alfred C. L., New York, N. Y.
Hemstreet, John G., Jackson, Mich.
Herbig, Rudolph O., Cincinnati, Ohio
Hern, George P., Newark, N. J.
Hill, Robert N., Chicago, Ill.
Hollingsworth, Fred L., Atlanta, Ga.
Hunter, Charles H., Easton, Pa.
Hunting, Ralph W., Phoenix, Ariz.
Hyman, Benzion, Toronto, Ont.
Ingles, Harry C., Minneapolis, Minn.
Jacobson, Alfred T., W. Allis, Wis.
Jaeger, Walter H., Peterboro, Ont.
Jaques, Arthur, New York, N. Y.
Jeffery, John J., Toronto, Ont.
Jerauld, Rodman E., Salt Lake City, Utah
Kameyama, Toru, Schenectady, N. Y.
Kauffman, L. W., Baltimore, Md.
Keers, John K., Jr., New York, N. Y.
Kelleher, James, Toronto, Ont.
Keller, Emanuel, Newark, N. J.
Kelley, Leo A., New York, N. Y.
Kelly, Albert G., Yonkers, N. Y.
Kemp, William B., Detroit, Mich.
Kent, Joseph B., San Francisco, Cal.
King, Cecil W., Port Richmond, N. Y.
Kirchner, Lester F., Washington, D. C.
Kline, William H., St. Louis, Mo.
Kloeffer, Royce G., Manhattan, Kans.
Kritzmarher, Harry L., Newark, N. J.
Lambe, Alfred B., (Member), Ottawa, Ont.
Lang, John J., Detroit, Mich.
Lanoue, Alexander J. R., Montreal, Que.
Lauderdale, Fernando S., Wilkinsburg, Pa.
Laven, Harris, New York, N. Y.
Lawson, Denhart K., Pittsburgh, Pa.
Leslie, Fred A., Baltimore, Md.
Levy, Charles H., Jr., New York, N. Y.
Lewis, D. K., (Member), Winnipeg, Man.
Lindsay, William H., Pittsburgh, Pa.
Loux, Raymond A., Nashwauk, Minn.
Love, Robert M., Toronto, Ont.
Luerssen, George A., (Member), Newark, N. J.
Lynch, John P., Boston, Mass.
MacLean, Ian M., Peterboro, Ont.
Malwitz, Ray C., Chicago, Ill.
Marks, Alexander, (Member), New York, N. Y.
Martina, Sylvio W., Milwaukee, Wis.
Martindale, Roy, (Member), Los Angeles, Cal.
McClung, Donald R., Portland, Ore.
Mercier, Cyril A., Scranton, Pa.
Michaelson, Arthur R., New York, N. Y.
Miller, George M., Louisville, Ky.
Miller, W. Ray, Erie, Pa.
Milne, Winford G., Hamilton, Ont.
Mintz, Jay J., New York, N. Y.
Mitchell, Charles T., Point Gray, Vancouver, B. C
Mitchell, Earle A., Yonkers, N. Y.
Moffatt, William R., Toronto, Ont.
Mohr, Franklin, New York, N. Y.
Moir, Daniel F., Marysville, Mich.
Montgomery, Robert G., Baltimore, Md.
Moore, Charles A., Windber, Pa.
Moser, Walter A., Salt Lake City, Utah
Myers, Don E., Beardstown, Ill.
Nash, Albert E., Erie, Pa.

Synchronous Motors for Ship Propulsion

BY E. S. HENNINGSEN
General Electric Co., Schenectady, N. Y.

SINCE the inception and development of the idea of electric ship propulsion, the question of the possibility of using synchronous motors for such service has often been raised. Such a motor could be designed for unity power factor with a resulting saving in cost, weight, and efficiency, of both motor and generator. So far as mechanical design was concerned, the answer was, of course, that the same substantial mechanical features could be obtained with a synchronous motor as with an induction motor. In addition, the synchronous motor would have greater clearance between rotor and stator and repairs could be more easily made since it would not be necessary to remove the rotor to replace either field or armature coils. The question, therefore, was whether or not satisfactory electrical characteristics could be obtained with this type of motor. The affirmative answer to this question is attested to by the fact that the S. S. *Cuba*, a fast passenger and express boat belonging to the Miami Steamship Company, and the first vessel of any kind to be propelled by a synchronous motor, has been in successful operation since November 1920, and five more equipments are under construction. Four of these are to drive cutters being built for the U. S. S. Coast Guard Service and one for a fruit steamer.

The first consideration in the problem was to determine as accurately as possible what the torque requirements were, first under normal operation, and second, during reversal of the propeller. The only point in question under normal operation is the margin in break-out capacity that is required to keep the motor in step during rough weather or when the ship is making a turn. From the limited data available on single-screw ships, it appears that the torque imposed on the propeller, due to the pitching of the ship in rough weather, varies between zero and about 175 per cent of the average. The period of this variation in torque is about seven seconds. However, this requirement is not peculiar to the synchronous motor drive, since it is equally necessary to meet this condition with any form of electric drive. Since the break-out capacity depends upon the ratio of no-load ampere turns to synchronous impedance ampere turns and also upon the amount of field excitation that can be carried on both motor and generator, sufficient break-out torque is simply a question of proper design.

The torque required to reverse the propeller under full speed conditions has been accurately determined for battleships by the Navy Department, and is illustrated in Fig. 1 for the U. S. S. *Delaware*.[1] This curve, which assumes that the ship continues ahead at full speed, shows that when the driving torque is reduced to zero, the propeller drops to the no-slip speed which is 76 per cent of its full speed. To

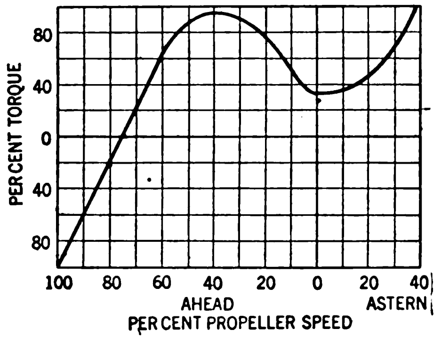

FIG. 1—CURVE OF TORQUE REQUIRED TO REVERSE THE PROPELLERS OF THE U. S. S. *Delaware*

bring the propeller to rest against the action of the water requires a constantly increasing torque until at about one-half of the no-slip speed, the maximum braking torque is reached. This value is about 95 per cent of full torque. Below the speed the required torque falls off and at zero propeller speed is about 33 per cent. One hundred per cent of normal torque is required to drive the propeller at 38 per cent speed backwards. These values will, of course, be somewhat lower due to the retardation of the ship during the time required for switching and reversing. No such accurate curve is at present available on a single-screw ship, but tests on several such ships indicate

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

1. From an article by Lieut. S. M. Robinson, U. S. N., *Journal American Society Naval Engineers*, February 1916.

that the torque required to reverse the propeller is materially less than that shown in Fig. 1. It is, therefore, safe to assume that this curve represents the maximum torque requirements that must be met during reversal.

In land practise, motors are usually operated from a constant potential and constant frequency system. For ship drive, since the main power circuit comprises only the generator and the motor, it is neither necessary nor economical to design for

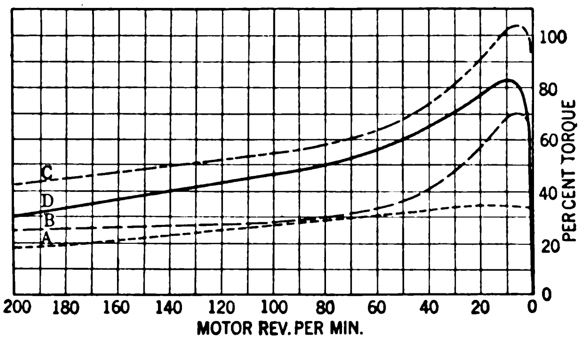

FIG. 2—BRAKING TORQUE TEST—GENERATOR AND SYNCHRONOUS MOTOR CONNECTED TOGETHER WITH OPPOSITE PHASE ROTATION

either constant potential or constant periodicity during the operation of reversing. In other words, both motor and generator may be overexcited for brief periods and advantage may be taken of the fact that the generator's speed can be reduced until the motor has been synchronized and the two units then brought up to speed together. Based on these facts a number of methods of reversal were suggested and tested out on an equipment consisting of the following machines: A 375-kv-a. generator, driven by a 3600-rev. per min. turbine, was used to supply power to a 36-pole, 275-h. p. synchronous motor. The propeller was represented by a 200-kw. direct-current generator mounted on the same shaft with the motor. By varying the field excitation of the motor-driven exciter to which the d-c. generator was connected, the load on the synchronous motor could be reversed and varied rapidly enough to approximate very closely the propeller torque curve of Fig. 1.

The results of some of the tests made on this equipment may be briefly summarized as follows:

1. The first method to be tried out was to cut off the steam from the turbine, reverse the phase rotation between motor and generator, establish field excitation on both machines, allow the turbine to come to rest with the motor and then start up by admitting steam to the turbine, bringing the motor up in synchronism with the generator from zero speed. Although sufficient braking torque could be developed by this method, it was not found to be feasible because the amount of load that could be started was very small when the number of poles of the generator differed widely from those of the motor. On the particular motor and generator used in these tests, it was found that with normal full load field current on each, the motor could just be started with no-load on the d-c. generator. With 190 per cent of normal full load field current on each only 22½ per cent of normal load could be started. This method is also objectionable on account of the high temperatures that result when steam is admitted to the turbine at standstill.

2. The second suggestion was to reverse the phase rotation and establish both fields as before but allow the generator to drop to only one-fourth speed. The objection to this method was the excessive mechanical vibration that resulted when the motor was at standstill but still excited and the generator running (also excited) at one-quarter speed. In this connection it is interesting to note the test shown in Fig. 2. Curve *A* represents the torque developed by the amortisseur winding of the motor with normal excitation on the generator field and the motor field short-circuited. Curve *B* represents the torque developed by the motor functioning as a generator with normal excitation on the field and the armature leads connected to those of the generator. It was expected that with both fields normally excited, the resulting torque curve would be the sum of curve *A* and curve *B*, or curve *C*.

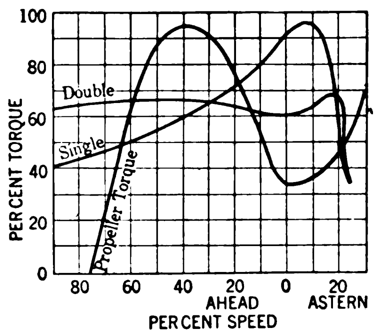

FIG. 3—COMPARISON OF THE TORQUE CURVES OF A SYNCHRONOUS MOTOR WITH SINGLE AND DOUBLE AMORTISSEUR WINDINGS

The generator was held at one quarter normal speed and had the same field excitation for each curve.

Instead, the resultant curve *D*, obtained from test, shows that due to interference of the two polyphase systems of opposite phase rotation, the resulting torque is only about 86 per cent of the sum of the separate torques.

3. The motor was then equipped with a double amortisseur winding to find out whether the advantage so gained would be worth the added mechanical difficulty. Fig. 3 shows the test curves obtained with both the single and double amortisseur windings. The generator was run at one quarter of full speed

and with the same field excitation for both curves. It will be noted that the double winding will give a slight gain in the time of stopping the propeller, but an almost equal loss in time to come up to speed

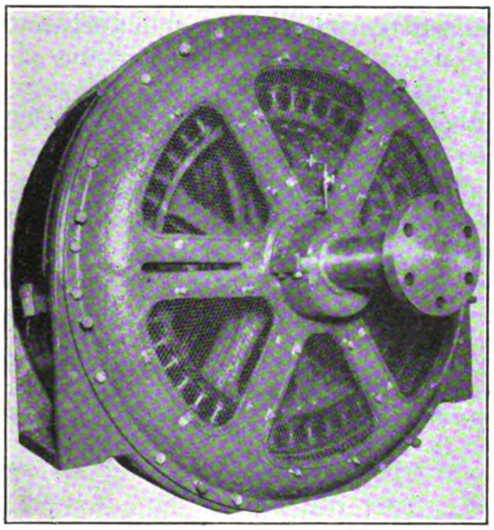

Fig. 4—Coupling End of 46-Pole, 2600-H. P., 50-Cycle, 130-Rev. per Min., Synchronous Motor for Ship Propulsion

in the opposite direction, hence practically no advantage will be obtained with the double winding.

4. It was found that with a given field excitation on both generator and motor, a 10 per cent greater maximum load could be carried before the motor would fall out of step when the load was varied between zero and a maximum in a seven-second period, than when the load was gradually applied. Also when the swinging load was increased somewhat and the motor fell out of step on the high swing it would pull back into synchronism on the low swing.

5. The tests showed that the two most satisfactory methods of accomplishing a full speed reversal of the propeller are as follows:

Method No. 1: (a) Throw the turbine speed governing mechanism to the quarter speed position; (b) reverse the phase rotation between motor and generator; (c) excite the motor field only, thus causing the motor to function as a generator and hence brake the propeller to zero speed; (d) energize the generator field and deenergize the motor field, thus causing the motor to come up to approximately one-fourth speed as an induction motor; (e) apply motor field to synchronize, and (f) bring up the turbine speed.

Method No. 2: (a) and (b) same as in Method No. 1, (c) establish field on the generator, thus causing the motor to come to rest and up to approximately one-quarter speed in the opposite direction by means of the amortisseur winding torque only; (d) apply motor field to synchronize, and (e) bring up the turbine speed.

Method No. 1 although requiring one more operation has the advantage that very much higher braking torque can be obtained from the generator characteristic than from the induction motor torque characteristic and also that it affords a means of keeping the propeller from rotating while the ship is still going ahead due to its momentum, a procedure which is not possible without complicated control when only the induction motor torque characteristic is used.

The construction of synchronous motors for ship drive is illustrated by Figs. 4 and 5. They differ in the following particulars from those designed for land practise: The diameter is smaller and the length correspondingly greater; they are of the end shield bearing type; the air gap clearance is somewhat greater; special precautions are taken to make the insulation moisture-proof; the amortisseur winding is so constructed that the poles may be removed without removing the rotor; jacking bolts are provided in the bearing housings for taking the weight of the rotor when it is desired to remove a bearing. In

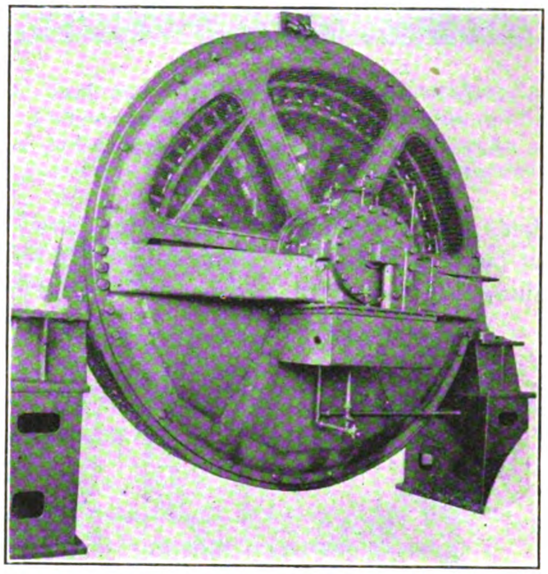

Fig. 5—Thrust Bearing End of 60-Pole, 3000-H. P., 50-Cycle, 100-Rev. per Min., Synchronous Motor for Ship Propulsion

order to facilitate temporary repairs, the armature winding has as large a number of circuits as the number of poles will permit. Then in case of a burn-out it is only necessary to cut out that particular circuit or circuits without having to install jumpers across the damaged section. Since the power to drive the propeller varies approximately as the cube of the speed, cutting out one circuit of a twelve-circuit winding, for instance, would mean a drop in speed of only a little more than 2½ per cent to keep the load on the other circuits as before.

The motor illustrated in Fig. 5 has the ship's main thrust bearing installed in the forward lower bearing bracket, the upper part of which is made in the form of a deep beam. Details of this spring thrust bear-

ing are shown in Fig. 6. Lubrication of the thrust bearing and horizontal bearings is furnished by an oil pump, driven from the main shaft and mounted in an oil tank bolted to the under side of the bearing

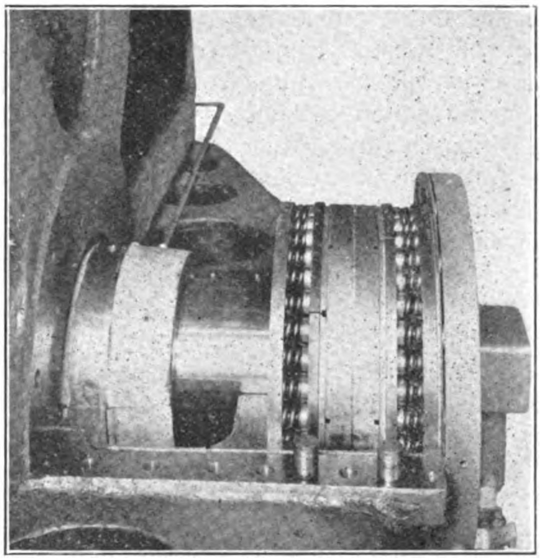

Fig. 6—3000-H. P., 50-Cycle, 100-Rev. per Min., Synchronous Motor for Ship Propulsion

With bearing caps removed to show one journal bearing and spring thrust bearings assembled in lower bearing bracket.

bracket. This particular design of the motor, thrust bearing, and oil system as a unit, contemplated installing the motor in a separate compartment as

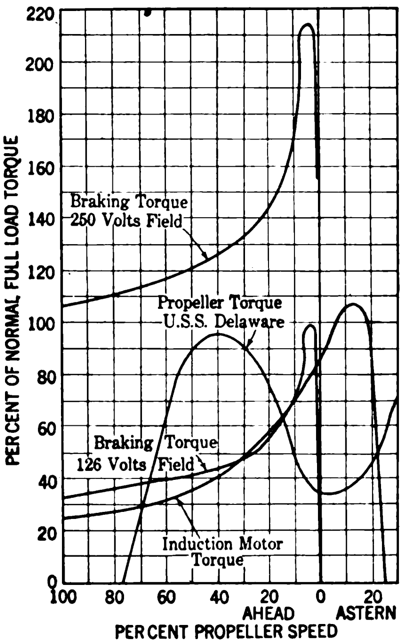

Fig. 7—Torque Characteristics—3000-H. P., 100-Rev. per Min., Synchronous Motor

far aft as possible and hence doing away with the usual long shaft alley. In such an installation a gravity feed oil system could be installed to be used in case of a failure of the direct-connected oil pump. With such low speeds as are employed, very little lubricating oil is required and a comparatively small gravity tank would supply oil until repairs could be made. With a motor such as shown in Fig. 4, the spring thrust bearing is mounted in a separate housing.

Fig. 7 shows the torque characteristics of an equipment consisting of a 3000-h. p., 100-rev. per min. synchronous motor and a 3000-h. p., 3000-rev. per min., 50-cycle turbo-generator installed on the S. S. *Cuba*. The curves marked braking torque show the torque developed by the motor functioning as a generator with both 125 volts and 250 volts across the collector rings. The motor is connected to the generator with opposite phase rotation but the field of

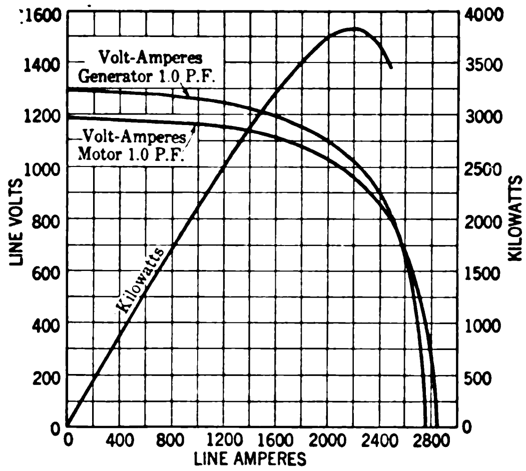

Fig. 8—Load Characteristic at Full Excitation—3000-H.P., 3000-Rev. per Min. Generator and 3000-H. P., 100-Rev. Min., Synchronous Motor

the generator is not excited. The curve marked induction motor torque is the torque developed by the amortisseur winding of the motor. For this curve the generator is running at one-fourth of normal speed and has twice the normal excitation voltage impressed across the collector rings. This double excitation is obtained by means of a 250-125-volt, three-wire exciter. During normal operation the generator and motor fields are connected across the 125-volt circuits and during reversal across the 250-volt circuit. The propeller torque curve given in Fig. 1 has also been plotted in Fig. 7. As mentioned before this curve is considerably higher than that of a single-screw vessel. Tests made on the S. S. *Cuba* showed that the propeller could be brought to rest from full speed in three and one-half seconds by means of braking with 220-volt excitation; in twenty-seven seconds by braking with 110-volt excitation; and in thirteen seconds with the motor operating as an induction motor.

The load characteristic of this equipment is given in Fig. 8. With 125-volt excitation across the collector rings, the margin in break-out capacity is 161 per cent for a steadily applied load. Somewhat

more than this can be safely carried when the load is a variable one such as will result due to the action of the waves and rough weather.

The successful application of synchronous motors to ship propulsion, therefore, marks another advance in the ever widening field of activity of this type of motor. It is certainly to be expected that the same high record of substantial and reliable performance that it has established in other lines of industry will be duplicated in the marine field.

The Electric Strength of Air under Continuous Potentials and as Influenced by Temperature

BY J. B. WHITEHEAD and F. W. LEE
of the Johns Hopkins University

The paper describes a series of experiments on the influence of temperature on corona-forming continuous potentials. The observations have been made on three sizes of wire of diameters 0.0251 cm., 0.0803 cm., and 0.0933 cm., and in each case at several values of temperature within the range 5 deg. cent and 70 deg. cent. At each temperature the pressure has been varied from a value in the neighborhood of that of the atmosphere downwards; reaching in the extreme cases the value 6.03 cm. of mercury. Within the range of values reached, as indicated above, the general form of the law of corona, as developed experimentally by a number of other observers, is found to be fulfilled. There are separate families of curves for positive and negative potentials as obtained by varying the pressure for each constant value of temperature.

The observations show that under constant conditions as to pressure and temperature a higher value of negative potential than positive potential is required to form corona.

As plotted graphically, the results seem to indicate that when larger wires are used corona appears at the same values of both positive and negative potential. The observations, however, have not been extended sufficiently to show this identity of value. This conclusion is at variance with the observations of a number of other experimenters, in particular those of W. S. Brown, who concludes that with larger values of diameter of wire negative corona may appear at lower values than positive corona.

The experiments substantiate the empirical laws developed by Whitehead and Peek, although the constants of the equations involved are higher than any heretofore observed. There is some indications that at temperatures in the neighborhood of 70 deg. cent. a departure from the empirical laws mentioned may set in.

Introduction and Historical Setting

THE LAW of corona formation on round wires in air has been devised empirically from the observations of a number of experimenters. It involves the electric intensity at the surface of the wire, the radius of the wire, and the relative density of the air.

The empirical law has been investigated over quite wide ranges of values of radius of wire and air density as dependent on pressure. Comparatively few attempts have been made however to study the influence of temperature on corona formation. This paper describes a series of experiments in which corona voltages have been measured at several temperatures within the range of 5 deg. cent. to 70 deg. cent., the pressure being varied in each case from that of atmosphere downward, in the extreme cases to 6.03 cm. of mercury.

Continuous potential has been used throughout the work. Various investigators have shown that with alternating corona voltages the maximum values of the wave are very closely, if not identically, the same as the continuous voltage values.

The law of corona had its origin in the laws governing the sparking between plates. Townsend[2], upon the experiments formed by J. B. Baille[1], first stated the relation for the sparking voltage in air as given by the formula

$$V = 39\,P\,S + 1700 \tag{1}$$

Where V = voltage between two parallel plates,
P = pressure of the gas,
S = the distance between the plates.

This formula by dividing through by $P\,S$ gave use to the relation

$$\frac{E}{P} = 39 + \frac{1700}{P\,S} \tag{2}$$

Since the electric intensity between the plates is uniform and therefore $\frac{V}{S} = E$. The relation concentrated the attention upon the electric intensity and not upon the total voltage. Townsend in his development of secondary ionization first showed that in a corona tube the distance S in the above formula is that of the path which an ion traverses in the greatest field and therefore is next to the wire. Under this consideration the above formula for the corona tube is,

---

To be presented at the Annual and Pacific Coast Convention of the A. I. E. E., Salt Lake City, June 21-24, 1921.

$$\frac{E}{P} = A + \frac{B}{r_w} \cdot \frac{1}{\sqrt{P}} \tag{3}$$

Where A and B are constants of the phenomena and r_w is the radius of the wire. This equation giving the law of corona formation was first developed experimentally by Whitehead, Peek and others, and Townsend has shown that it may be derived from his experiments on gaseous ionization at low pressures and that it is in accord with the theory of ionization by collision.

Whitehead[3] first determined these constants in a corona tube for air under normal conditions. Peek[11] later showed that the density or the pressure and the temperature together affected the formation of corona and established the density factor δ.

$$\delta = \frac{3.92\,P}{T} \tag{4}$$

where P = pressure of the gas in centimeters of mercury,
T = absolute temperature in degrees centigrade.

The corona formula then reduced to the form

$$\frac{E}{\delta} = A + \frac{B}{\sqrt{\delta\, r_w}} \tag{5}$$

which it has at present.

Whitehead[3] and Peek[11] carefully investigated the values of A and B with alternating potential by changing δ, r_w, humidity of the air and the material

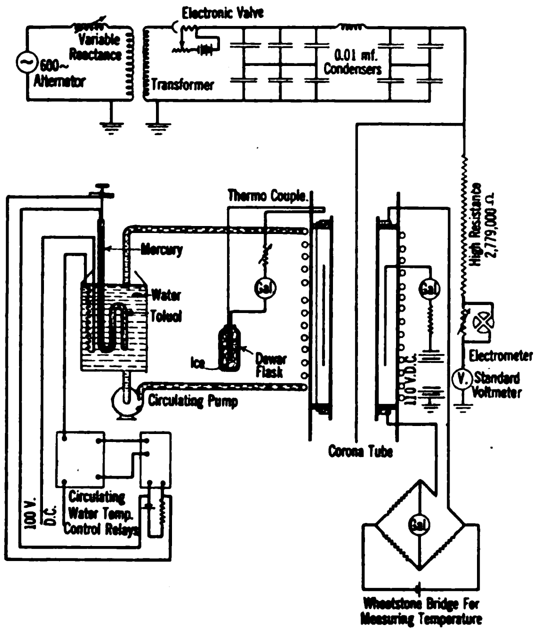

Fig. 1—Connection of High-Potential Voltage to Corona Tube and Auxiliary Apparatus

of the wire. Later Whitehead and Brown[3] also determined the constants A and B with continuous potentials by changing the diameter of the wire. Farwell[6], Watson[4] and Schaffers[5] also worked with direct potentials upon corona. Their method of detecting corona was mostly visual and with the methods and material available at that time they secured qualitative results which later experiments under more favorable conditions to a larger degree confirmed. It remained for Whitehead and Pullen[3] to develop a tube which gave more sensitive indications of corona.

This experimental investigation aims to continue the work of Whitehead and Brown[3] with continuous potentials. The immediate purpose was to investigate the constants A and B with positively and negatively charged wires under different temperatures and variable pressures at each temperature.

Description of Apparatus

The source of high continuous potential in these tests was secured from a "kenotron"* or rectifying vacuum tube, in connection with a high voltage transformer and condensers. Fig. 1 indicates the manner in which they were connected and how they were controlled.

The alternator was a two-armature generator designed to operate at either 600 cycles or at 3000 cycles and was directly connected to a three-h. p., 220-volt continuous-current shunt motor. The motor power, as well as the field excitation were secured from a 450-ampere-hour, 110-220-volt storage battery to insure steadiness of alternating potential.

The voltage to the transformer was controlled by a variable iron reactance. This reactance consisted of two coils mounted upon the legs of a core type transformer in which the core could be adjusted. The adjustment was accomplished by a screw having a pitch of twenty threads to the inch, and in this way the reluctance of the magnetic circuit was changed; and this in turn changed the ratio of voltage upon the transformer and the reactance coil. The generator voltage remained constant. In this way the high potential voltage could be raised in a continuous manner with an exceptional degree of adjustment.

In the high-tension circuit of the transformer a kenotron was connected in series with a battery of condensers, of which each unit had a capacity of 0.01 microfarad. The kenotron was designed for 40,000 volts and 1/10 ampere. In this experiment the voltage was limited by the condensers to 20,000 volts. The current taken by the exciting coil of the kenotron was six amperes for 100 per cent electronic emission. The resistance of the heating filament, a ten-mil tungsten wire was one ohm. The construction and theory of the kenotron are now quite well understood and thoroughly described by Dushman[7]. A small storage battery of six cells in series with a small carbon compression rheostat was sufficient to properly excite and regulate the filament current. The kenotron together with its exciting apparatus

*Name given by General Electric Company to a rectifing Fleming valve.

was carefully insulated from the ground by wooden insulators and logical grouping.

The condensers were of the oil-insulated high-potential type and were grouped into two batteries, one of six units, the other of four units each. The combined capacity of the first condenser battery was 0.015 microfarad and the combined capacity of the second condenser battery was 0.01 microfarad. The needle gap of each condenser was adjusted to 10,000 volts, thereby making the voltage across two condensers 20,000 volts. Between these two batteries was connected an inductance of 0.027 henry. According to Hull[8] the voltage fluctuation would be,

$$V = \frac{8\,i\,\pi}{L\,w^3}\left(C + \frac{1}{L\,w^2}\right)^2 \qquad (6)$$

$$= 4.62 \times i \times 10^{-10} \text{ volts}$$

where C = total capacity in farads,

$w = 2\,\pi\,f = 2\,\pi \times 600$ angular velocity in radians per sec.

L = coefficient of self-induction in henrys between condenser batteries,

i = current taken from the second condenser battery.

The current i which was used in the voltage measuring circuit never exceeded 0.01 ampere. From the above formula it is seen that the correction factor is negligible. That this coincided with experimental observations was tested by Brown[3].

The voltage was measured with a precision Weston voltmeter in series with a resistance of 1,428,000 ohms of manganin wire and of 1,343,000 ohms of lavite resistances. About 50 watts was the maximum rate of energy dissipation in the form of heat in this circuit. The quadrant electrometer connected as shown

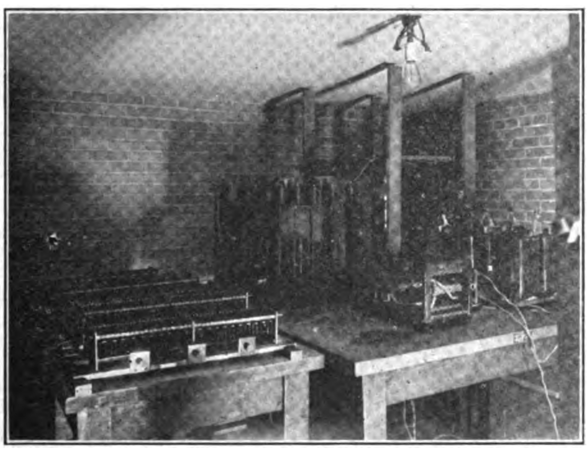

Fig. 2

was not used for detecting corona voltage, but for other purpose to be described later. The resistance in this circuit did not change within the range of 1 per cent in this experiment as tested by a Wheatstone bridge upon the summation of the individual units composing this resistance. (See Fig. 2.)

The corona tube as constructed for this experiment was similar to the one constructed before by Whitehead[3] and Pullen[3]. The main chamber was constructed from a piece of 6-in. steel piping 19 in. long. This pipe was carefully bored out in a lathe so as to receive the concentric cylinder supports and perforated corona cylinder. (See Fig. 3.) Around the inner 4-in.

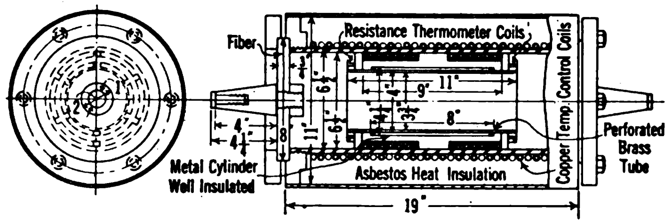

Fig. 3—Diagram Showing Construction and Dimensions of Tube

brass cylinder was another metal cylinder carefully insulated from it. This insulated cylinder received a small fraction of the corona current and, in conjunction with a galvanometer, served to indicate the presence of corona. (See Fig. 1.) The tube was closed at each end by a fiber head which also supported the central wire. Glass, one inch thick, was first tried for this purpose, but it was found that it was unable to withstand the stress due to internal pressure. The fiber used for this purpose was thoroughly boiled in paraffin to expel all moisture. Glass windows were inserted into this fiber to observe the condition of the wire at all times. Around the outside of this cylinder were wrapped coils of copper tubing to serve as heating or cooling coils to the apparatus. These coils of copper tube were further insulated as to heat on the outside by an asbestos heat insulating compound. Directly above and below the inside brass cylinder, but out of the electric field, were placed two copper wire coils each having a resistance of two ohms. These two coils were connected in series and served as a resistance thermometer. A thermocouple was also placed in the tube well away from the iron walls, to measure the temperature of the gas. The thermocouple was made with a very small heat capacity so as to quickly acquire the surrounding temperature, and thereby give an indication of any quick change of temperature of the gas inside of the tube. All of the joints were carefully packed with string first immersed in a packing compound. Insulated terminals were taken from the tube by the aid of spark plugs. The pipe joints were all well coated with litharge before finally adjusting them. All of the cylinders were machined to align centrally and the adjustment was within one-hundredth of an inch. Upon the outside of the tube was placed a spring, as shown in Fig. 4, which served to keep

the wire taut with changes of length of tube arising from the unequal expansion to the tube and its wire.

The temperature of the circulating water used in maintaining the temperature of the tube was controlled by a special thermostatic regulator. This regulator consisted of a glass tube of 3/16-in. bore, sealed at one end, filled with mercury and toluol, as indicated. Since the coefficient of volumetric temperature expansion of mercury is too small for

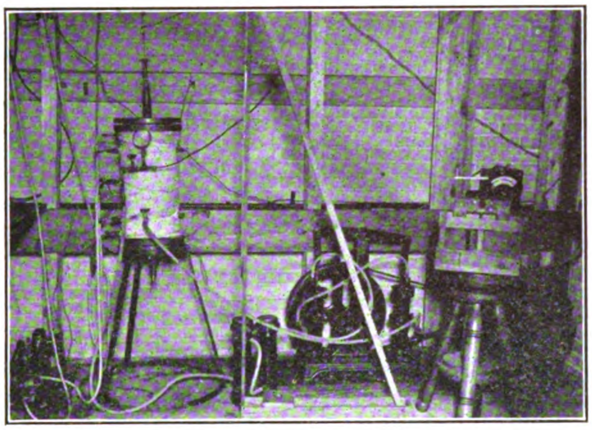

FIG. 4

sensitive regulation, toluol was also placed in this tube, as shown in the diagram of connections. The mercury acted as a seal for the very volatile toloul and at the same time served as a conductor in all the control circuits. The circulating water was heated with an immersion iron wire rheostat and was capable of carrying, when submerged, fifty amperes. This current was automatically interrupted by a remotely controlled switch, when the water had risen to its predetermined temperature. The control circuit of this switch was operated through a telegraph relay since it was necessary to interrupt this control circuit at a difference of potential of 110 volts d-c. A six-volt storage battery was used to excite this relay connected in series with a resistance. When the mercury in the tube had risen sufficiently high it short-circuited the battery connection to the relay and thereby opened the remotely controlled switch. As soon as the temperature receded this short circuit was removed and allowed the heating current to reestablish itself. The final temperature of the cirlating water was adjusted by means of a regulating screw. The height of this regulating screw determined the amount of expansion which the mercury and toluol could have before actuating the control circuits.

This constant temperature water was circulated by a positive rotary pump through the heating coils of the tube. By this method the corona tube reached a final steady temperature after one and one-half hours. The difference in temperature of the circulating water and of the gas in the tube was three degrees when operating in a steady state. Temperatures lower than room temperatures were secured by using cracked ice in the circulating water supply tank. The temperature of the circulating water in this case was that of melting ice, which was sufficiently constant for the experiment. In a like manner the temperature of one thermal junction was kept constant; only here a Dewar flask or thermos bottle was used to keep the ice from melting too rapidly.

The vacuum pump used to exhaust the corona tube was a small "Gyrek" model belted to a motor. (See Fig. 4.) The pressure was measured directly with a mercury manometer. Needle valves were used in all of the pressure control tubes to assure positive closing of the air connections.

From Fig. 5 it is seen that with the arrangement employed here it was possible to use but one lamp for illuminating the galvanometer mirrors, and also one scale sufficed to measure their deflection. The scale in this case was constructed from a ten-foot California redwood board bent into the arc of a circle of ten feet radius and mounted ten feet from the temperature measuring galvanometer. For indicating the presence of corona a D'Arsonval galvanometer slightly underdamped was used. This galvanometer ordinarily had a sensitivity of 83 megohms but with the above scale arrangement it was increased to 250 megohms.

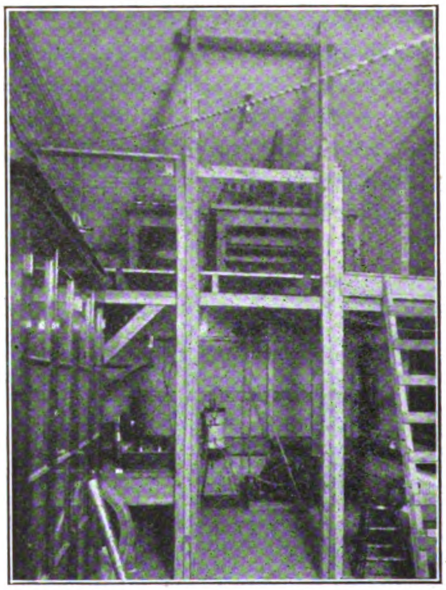

FIG. 5

It was found expedient, because of the large amount of apparatus used for operating this experiment, to separate the high-potential apparatus from the remainder by a platform. The platform was constructed above the corona tube, as is shown in Fig. 5. In this way it was possible to do all of the manipulating with dispatch and without any danger of coming into contact with high-potential circuits.

Preliminary Experiments

The method of securing high-potential direct-current voltage was substantially the same as that used by Brown[8]. However, it was found more convenient to control the alternating-current potential across the transformer with a reactance than with the field circuit of the alternator.

The voltmeter used in these tests was a precision Weston model No. 1064. It was, however, checked with a Weston standard cell and a Leeds and Northrup potentiometer through its entire range and was found accurate within the limits of observation.

The resistances of the voltage measuring circuit were measured with a Leeds and Northrup precision bridge and checked from time to time.

The thermocouple was made from a junction of "Advance" and copper wire and was calibrated with a standard mercury thermometer in a bath of water well agitated and slowly cooling. With the aid of a resistance in the copper portion of this circuit it was possible to adjust the deflection to an exact multiple of the temperature unit. One degree centigrade corresponded to a deflection of two divisions upon the scale. The resistance of the galvanometer was 110 ohms and the extra resistance in the circuit was 1161 ohms, thereby making a total of 1271 ohms in this circuit.

This thermocouple was then used to calibrate the resistance thermometer in the corona tube. According to Dellinger,[10] this resistance should have a linear variation of temperature within the range of temperature from 0 deg. cent. to 70 deg. cent. Its calibration will therefore check the accuracy of both the variation of mercury thermometer and of uniformity of

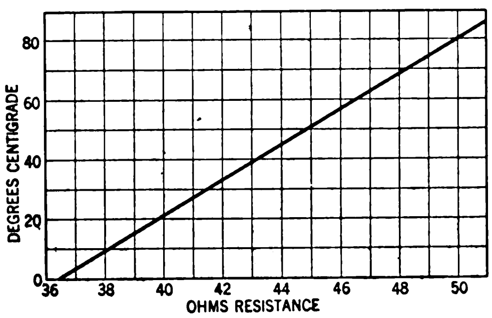

Fig. 6—Calibration of Resistance Thermometer With Thermocouple

temperature distribution in the tube. The temperature resistance curve upon this basis proved to be a straight line and hence the errors were below that of observation. (See Fig. 6.) The calibrating was done by first bringing the tube to a high steady temperature and then allowing it to cool slowly. It required six hours to secure this calibration curve.

The question of insulation was a more difficult one. It was found that the metal electrode cylinder around the perforated brass cylinder had a resistance to ground of 20 megohms through the hard rubber insulation. This was changed by replacing the insulators with new hard rubber.

Since the foundation of generating high direct potential by this method presupposes almost perfect insulation, it was necessary to check all of the leaks to ground in the generating system. This was done by charging the high-potential side of the system to a difference of potential of forty volts to ground and observing the decrease of potential upon the quadrant electrometer. The relations which exist by measuring the resistance by the loss of charge method are:

$$V = V_0 \epsilon^{-\frac{1}{CR}t} \tag{7}$$

where V = 34.7 potential at time t = 10 seconds.
V_0 = 39 initial potential,
C = 0.025 capacity in farads,
R = the resistance to ground.

This resistance from the observations as shown by the test was 38×10^9 ohms. It is safe to conclude that even under the highest voltages the leakage

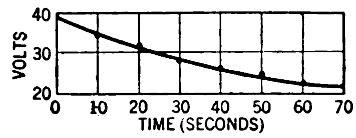

Fig. 7—Insulation Test With Quadrant Electrometer

current did not modify the potential within limits of observation. (See formula 6). Fig. 7 shows the insluation test with the quadrant electrometer.

Final Observations
